Although fish populations occur throughout the EMBA and Project Area, areas of particularly high fish diversity or abundances that are predicted to be contacted above thresholds include Scott Reef and Seringapatam Reef, Browse Island, Ashmore Reef and Cartier Island, Rowley Shoals, the Kimberley AMP and the Argo-Rowley Terrace AMP (probabilities of contact in relation to specific hydrocarbon fate are provided in **Table 6-158**). Fish assemblages in these areas are likely to include various species of site-attached reef fish assemblages and also species of pipefish and seahorses that are protected under the EPBC Act. Submerged banks and shoals that have low probability of contact above entrained and/or dissolved thresholds are also expected to support higher fish abundances than surrounding featureless, deepwater habitat, these being Barracouta Shoal, Eugene McDermott Shoal, Heywood Shoal, Hibernia Reef, Vulcan and Goeree Shoals and Fantome Bank. Coral reef fish generally have small home ranges and as reef residents they are at higher risk from hydrocarbon exposure than non-resident, more wide-ranging fish species. The exact direct impact on resident fish populations would be entirely dependent on actual hydrocarbon concentration, duration of exposure and water depth of the affected communities. In addition, the could be indirect consequences to site-attached fish assemblages due to the loss of coral habitat and subsequent recovery of the reef system. It is also noted that the early life stages (larval and fingerling) of resident fish populations are particularly sensitive to hydrocarbon exposure.

A number of KEFs also overlap the EMBA, with many of these associated with high fish abundances and diversity. Impacts to KEFs and AMPs are discussed below.

Based on the outcomes of quantitative spill modelling, hydrocarbon spills resulting from the proposed Browse to NWS Project have the potential to significantly impact fish species, including protected species, within the Project Area and EMBA. Although such potential impacts could include mortality or sub-lethal injury/illness of fish, for most mobile species this would be expected to comprise a small proportion of the transitory populations (i.e. whale sharks, shortfin and long fin mako sharks). For species which are considered site-attached, such as reef fish and pipefish and seahorses, a hydrocarbon spill could potentially have higher level impacts (e.g. site-attached coral fish assemblages of Scott Reef).

Assessment against EPBC Act recovery and conservation plans and advices

Table 6-159 summarises how the risk of an unplanned hydrocarbon release associated with the proposed Browse to NWS Project is not inconsistent with the objectives and actions of the relevant EPBC Act recovery and conservation plans and advice for protected fauna.

Table 6-159 Alignment with EPBC Act recovery and conservation plans and advices for protected fauna – unplanned hydrocarbon release

Fauna	Relevant plan(s)/ Conservation Advice	Plan/advice objectives and actions	Assessment
Migratory shorebirds	Wildlife Conservation Plan for Migratory Shorebirds (Commonwealth of Australia, 2015a)	Anthropogenic threats to migratory shorebirds in Australia are minimised or, where possible, eliminated.	With the implementation of controls, it is considered highly unlikely that impacts will occur to migratory shorebirds as a result of unplanned hydrocarbon release. Therefore, it is considered that the proposed activities are not inconsistent with the Wildlife Conservation Plan for Migratory Shorebirds.
Whale shark	Conservation advice *Rhincodon typus* whale shark (Threatened Species Scientific Committee, 2015a)	Assess the impacts of offshore installations and associated environmental changes (light spill, chronic noise, changed water temperature, localised nutrient levels) on whale sharks and mitigation options for these impacts.	No specific reference to hydrocarbon pollution is provided in the conservation advice. Given the low number and infrequent nature of whale shark presence in the Project Area, and the implementation of controls, it is considered highly unlikely impacts to whale sharks will occur as a result of an unplanned hydrocarbon release. Therefore, it is considered that the proposed activities are not inconsistent with the conservation advice.

Fauna	Relevant plan(s)/ Conservation Advice	Plan/advice objectives and actions	Assessment
Green turtle	The Recovery Plan for Marine Turtles in Australia (Commonwealth of Australia, 2017)	Management actions: + Manage anthropogenic activities to ensure marine turtles are not displaced from identified habitat critical to the survival. + Manage anthropogenic activities in BIAs to ensure that biologically important behaviour can continue. + In relation to the Scott Reef – Browse Island green turtle genetic stock, the priority action is to manage anthropogenic activities to ensure marine turtle are not displaced from identified habitat critical to their survival.	Risk to marine turtles have been assessed and will be managed in accordance with the Recovery Plan for Marine Turtles in Australia which includes the minimisation of chemical discharge as an overarching action area (Commonwealth of Australia, 2017a). In relation to the Scott Reef – Browse Island green turtle genetic stock, the priority action to manage anthropogenic activities to ensure marine turtle are not displaced from identified habitat critical to their survival is predicted to be met as the likelihood of an unplanned hydrocarbon release impacting marine turtles has been assessed as highly unlikely. Therefore, it is considered that the proposed activities are not inconsistent with the Recovery Plan for Marine Turtles.
Hawksbill turtle			
Pygmy blue whale	Conservation Management Plan for the Blue Whale (Commonwealth of Australia, 2015c)	Acute chemical discharge (oil or condensate spill) is identified as a moderate risk to pygmy blue whales, however, there are no specific actions identified.	With the implementation of controls, it is considered highly unlikely that impacts will occur to cetaceans as a result of unplanned hydrocarbon release. Therefore, it is considered that the proposed activities are not inconsistent with the Conservation Management Plan for the Blue Whale or the conservation advices listed.
Humpback whale	Conservation advice *Megaptera novaeangliae*, Humpback Whale	Marine discharges have not been identified as a direct threat to these whale species; however, habitat degradation has been identified as a threat and unmanaged discharges may contribute to this threat. The conservation advice relevant for this threat – identifies modification to the coastal region in areas of importance to listed whales may result in reduced occupancy, compromised reproductive success and even mortality.	
Sei whale	Conservation advice *Balaenoptera borealis*, Sei Whale		
Fin whale	Conservation advice *Balaenoptera physalus*, Fin Whale		

Key Ecological Features

Change in sediment quality, change in water quality, injury or mortality to fauna

KEFs have the potential to be impacted through exposure to hydrocarbons in the event of an unplanned hydrocarbon release. Based on the outcomes of quantitative spill modelling for Scenarios 1 to 4, the following KEFs have the potential to be impacted at varying probabilities of exposure above threshold concentrations for floating, dissolved and entrained hydrocarbons (see Table 6-158):

- Continental slope demersal fish communities
- Seringapatam Reef and Commonwealth waters in the Scott Reef complex
- Ancient coastline at 125 m depth contour
- Mermaid Reef and Commonwealth waters surrounding Rowley Shoals
- Ashmore Reef and Cartier Island and surrounding Commonwealth waters

Although these KEFs are primarily defined by seabed geomorphological features, they are described to identify the potential for increased biological productivity and, therefore, ecological significance. The values and sensitivities of these KEFs primarily relate to seafloor features and demersal fish species (i.e. that live close to the seafloor). Therefore, water depth can determine whether any hydrocarbons (i.e. dissolved and entrained) can potentially interact with these values and sensitivities. Some KEFs, such as those defined around Scott Reef, Ashmore Reef and Cartier Island, and Rowley Shoals, also have shallow and emergent features and are, therefore, more vulnerable to the impacts of hydrocarbon spills. These KEFs have added protection of being Commonwealth and State protected marine parks.

Potential impacts to KEFs include the contamination of sediments, impacts to benthic fauna/habitats and associated impacts to demersal fish populations and reduced biodiversity. Most of the KEFs within the EMBA have relatively broad-scale distributions and are unlikely to be significantly impacted.

Summary

Table 6-160 provides an assessment of the risk of unplanned hydrocarbon discharge in relation to the pressures on KEFs identified in the Marine bioregional plan for the North-west Marine Region (Commonwealth of Australia, 2012).

Table 6-160 Alignment with protection of conservation values of KEFs – unplanned hydrocarbon release

Key Ecological Feature	Relevant plan(s)	Relevant pressures	Assessment
Ashmore Reef and Cartier Island and surrounding Commonwealth waters	Marine bioregional plan for the North-west Marine Region (Commonwealth of Australia, 2012).	Oil pollution currently identified as "of potential concern"	With the implementation of controls, it is considered highly unlikely that impacts will occur to KEFs as a result of unplanned hydrocarbon release. Therefore, there is a high level of confidence that there will not be an adverse impact to marine ecosystem function or integrity with in the KEFs; or any reduction to the conservation values of the KEFs will occur.
Seringapatam Reef and Commonwealth waters in the Scott Reef Complex			
Mermaid Reef and Commonwealth waters surrounding Rowley Shoals			
Ancient coastline at 125 m depth contour		Oil pollution currently identified as "of less concern"	
Continental slope demersal fish communities		Oil pollution currently identified as "no of concern"	

Australian marine parks

Change in sediment quality, change in water quality, injury or mortality to fauna

AMPs have the potential to be impacted through exposure to hydrocarbons in the highly unlikely event of an unplanned hydrocarbon release. Based on the outcomes of quantitative spill modelling for Scenarios 1 through 4, the following AMPS have the potential to be impacted at varying probabilities (Table 6-158):

- Kimberley Marine Park (highest probability is 31% probability for entrained hydrocarbons)
- Argo-Rowley Terrace Marine Park (highest probability is 100% probability for surface hydrocarbons)
- Rowley Shoals Marine Park (highest probability is 34% for entrained hydrocarbons)
- Ashmore Reef Marine Park (highest probability is 18% probability for accumulated hydrocarbons)
- Cartier Island Marine Park (highest probability is 22% for accumulated hydrocarbons)
- Mermaid Reef Marine Park (highest probability is 34% for entrained hydrocarbons).

In the highly unlikely event of a worst-case scenario release, the open water environment protected within the AMPs may be affected by floating, dissolved, entrained, and/or shoreline hydrocarbons above thresholds. If hydrocarbons contact key receptor locations within these protected areas, such as islands and mainland coastlines or defined BIAs, significant impacts may occur, including the contamination of sediments and water, impacts to benthic fauna/habitats, impacts to protected and other marine fauna, and a potential to result in ecosystem level impacts (including a reduction in biodiversity).

Conservation values of these areas are described in Section 5.3.3. Potential impact on the values of these AMPs is discussed in the relevant sections above for ecological and physical (water quality) values and below for social (socio-economic) values.

Table 6-161 provides an assessment of the proposed seabed disturbance in consideration of the North-west Marine Parks Network Management Plan (Director of National Parks, 2018).

Table 6-161 Alignment with the North-west Marine Parks Network Management Plan – Risk of unplanned release of hydrocarbons

Australian Marine Park	Relevant plan(s)	Australian Marine Park objectives	Assessment
Argo-Rowley Terrace Marine Park Kimberley Marine Park Mermaid Reef Marine Park Cartier Island Marine Park Ashmore Reef Marine Park	North-west Marine Parks Network Management Plan (Director of National Parks, 2018)	**Sanctuary Zone (1a)** The objective of the Sanctuary Zone (1a) is to conserve ecosystems, habitats and native species in as natural and undisturbed a state as possible **National Park Zone (II)** The objective of the National Park Zone (II) is to provide for the protection and conservation of ecosystems, habitats and native species in as natural a state as possible. **Habitat Protection Zone (IV)** The objective to the Habitat Protection Zone (IV) is to allow activities that do not harm or cause destruction to seafloor habitats, while conserving ecosystems, habitats and native species in as natural a state as possible. **Multiple Use Zone (VI)** The objective of the Multiple Use Zone (VI) is to provide for ecologically sustainable use and the conservation of ecosystems, habitats and native species.	If a large hydrocarbon spill occurred as a result of the proposed Browse to NWS Project, AMPs could potentially be impacts (depending In the nature and location of the spill). However, as described above, it is considered highly unlikely that such a spill will occur. Therefore, it is considered that the risk of unplanned release of hydrocarbons as a result of the proposed activities is not inconsistent with the North-west Marine Parks Network Management Plan.

State marine parks and nature reserves

Change in sediment quality, change in water quality, injury or mortality to fauna

Based on the outcomes of quantitative spill modelling for Scenarios 1 through 4, the following State marine parks and nature reserves have the potential to be impacted at varying probabilities (Table 6-158):

- Scott Reef Nature Reserve
- Rowley Shoals Marine Park
- Lalang-garram/Camden Sound Marine Park (however, modelling only predicted the area to be contacted by localised shoreline accumulation above thresholds, i.e. not dissolved, entrained or floating hydrocarbons, at a probability of 1%).

In the highly unlikely event of a worst-case scenario release, these State marine parks and nature reserves may be affected by floating, dissolved, entrained, and/or shoreline hydrocarbons above thresholds. If hydrocarbons contact key receptor locations within these protected areas, significant impacts may occur including the contamination of sediments and water, impacts to benthic fauna/habitats, impacts to protected and other marine fauna, and a potential to result in ecosystem level impacts including a reduction in biodiversity.

Conservation values of these areas are described in Section 5.3.3. Potential impact on the values of these State marine park and nature reserves is discussed in the relevant sections above for ecological and physical (water quality) values and below for social (socio-economic) values.

Other protected places

Change in sediment quality, change in water quality, injury or mortality to fauna

In the event of an unplanned hydrocarbon release, the Scott Reef and Surrounds or the Mermaid Reef – Rowley Shoals Commonwealth Heritage Places may be affected by floating, dissolved, entrained and/or shoreline hydrocarbons above thresholds. If hydrocarbons contact key receptor locations within these protected areas, significant impacts may occur, including the contamination of sediments and water, impacts to benthic fauna/habitats, impacts to protected and other marine fauna, and a potential to result in ecosystem level impacts (including a reduction in biodiversity).

Conservation values of these areas are described in Section 5.4.3. Impact on the values of these protected areas is discussed in the relevant sections above for ecological and physical (water quality) values.

Other users

Changes to the functions, interests or activities of other users - Commonwealth and State managed fisheries

Four Commonwealth and 11 WA State fisheries overlap the Project Area, in particular the BTL (**Section 5.4.2.2**). Of these, six have been assessed as having the potential to actively operate within the Project Area (Development Area and BTL) and, therefore, be most likely to be impacted in the event of a hydrocarbon spill given their proximity to potential release locations.

In general, fisheries have the potential to be impacted by an unplanned hydrocarbon release through direct impacts to target populations or prey species and fishing gear and from the exclusion of users from a fishing area, potentially resulting in lost revenue.

Fish exposure to hydrocarbons can result in 'tainting' of their tissues. Even very low levels of hydrocarbons can impart a taint or 'off' flavour or smell in seafood. Tainting is reversible over time through the process of depuration which removes hydrocarbons from tissues by metabolic processes, although it depends on the magnitude of the contamination. Fish have a high capacity to metabolise these hydrocarbons while crustaceans (such as prawns) have a reduced ability (Yender et al., 2002).

Seafood safety is a major concern associated with spill incidents. Actual or potential contamination of seafood can affect commercial and recreational fishing and can impact seafood markets long after any actual risk to seafood from a spill has subsided (Yender et al., 2002). A major spill could result in the establishment of an exclusion zone around the spill-affected area, leading to temporary prohibition on fishing activities and subsequent potential economic impacts to affected commercial fishing operators. Additionally, hydrocarbons can foul fishing equipment such as traps and trawl nets, requiring cleaning or replacement. Depending on the release scenario and its severity, an exclusion zone could be a temporary localised area around the immediate vicinity of the release point or could cover a large portion of fishery or management zones and extend over a number of fishing seasons.

Based on the outcomes of quantitative spill modelling, hydrocarbon spills resulting from the proposed Browse to NWS Project would have the potential to impact commercial fisheries., with potential impacts including mortality or sub-lethal injury/illness of fish, with subsequent impacts to fishers as a result of reduction in catch.

Changes to the functions, interests or activities of other users – tourism and recreation, scientific studies

Tourism, recreation and scientific users have the potential to be impacted by an unplanned hydrocarbon release due to exclusion from an area or indirectly from a change in marine fauna behaviour, injury or mortality to marine fauna. Hydrocarbons can also accumulate on recreation areas predicted to be contacted and impact access to such areas due to any clean-up or decontamination activities. Tourists and recreational users may also avoid areas due to perceived impacts, including after the hydrocarbon spill has dispersed. Any impact to receptors that provide nature-based tourism opportunities may cause a subsequent negative impact to recreation and tourism activities.

Charter fishing, diving, snorkelling, whale, marine turtle and dolphin watching and cruising are the main commercial tourism activities in and adjacent to the North-west Marine Region. With the exception of offshore charter fishing, most marine tourism activities occur in State waters (DEWHA, 2008a). Recreational fishing tends to be concentrated in State waters adjacent to population centres (e.g. Broome) (DEWHA, 2008a). Engagement with regional tourism groups and Recfishwest indicate that only one to two recreational fishing charter operators run trips to Scott Reef approximately four to five times per year. Scott Reef has the potential to provide significant opportunities increased tourism; however, given the distance from closest landfall and costs, only a limited number of charter operators are prepared to take recreational fishers out to Scott Reef.

Similar activities occur or have the potential to occur at other key locations within the EMBA such as the Kimberley AMP, Seringapatam Reef, Ashmore Reef, Cartier Island and Rowley Shoals. However, the offshore waters of the Project Area and EMBA are not expected to support significant tourism or recreational activities. Should shoreline contact occur in the event of a spill, restricted access to beaches for a period of days to weeks may occur until natural weathering or tides and currents remove the hydrocarbons. Modelling results found localised areas of the Kimberley coast, as well as Timor Leste and Indonesia, have the potential to be contacted by shoreline hydrocarbons, however, as discussed in impacts to shoreline habitat, these areas are not expected to be significantly impacted. Hydrocarbons are not expected to reach any major inhabited areas.

Based on the outcomes of quantitative spill modelling, hydrocarbon spills resulting from the proposed Browse to NWS Project have the potential to impact tourism, recreational, scientific and traditional fishing activities in localised offshore areas such as Scott Reef and Rowley Shoals. However, even in the highly unlikely event of a large spill, potential impacts are likely to be restricted to short-term exclusion to an area with a potential for long term impacts to a small number of operators and users that visit these areas.

Changes to the functions, interests or activities of other users – shipping

Shipping has the potential to be impacted from an unplanned hydrocarbon release through exclusion to an area resulting in altered shipping routes and from increased operating costs (e.g. fuel consumption). Shipping activity is widespread across the NWS region. Shipping is sparse near the Browse Development Area, with the nearest main shipping channels approximately 50 to 100 km west of Scott Reef. However, a number of shipping channels do overlap or come in proximity to the BTL corridor.

In the highly unlikely event of a large spill, an exclusion zone may be established around the spill-affected area. This could result in exclusion of other users such as shipping vessels or vessels used by the mining and petroleum industries. Any exclusion zone established would probably be limited to the projected extent of floating hydrocarbons, estimated from spill modelling to be a maximum of between 67 and 143 km for Scenarios 1 through 4. The exclusion zone would probably be temporary, given the significant weathering predicted to take place within a few days of a worst-case scenario spill, therefore, physical displacement of vessels is unlikely to be a significant impact. Modelling did not predict surface hydrocarbons to reach any active port, therefore, there will be no impacts to these areas.

Changes to the functions, interests or activities of other users – industry

Industry, including other oil and gas operators, has the potential to be impacted from an unplanned hydrocarbon release through exclusion to an area or from a change to the functions, interests or activities of other users. The NWMR supports a number of industries including petroleum exploration and production, as well as minerals extraction.

In the highly unlikely event of a large spill, an exclusion zone may be established around the spill-affected area. The exclusion zone would extend from the spill source to encompass the projected limit of floating hydrocarbons (67 to 143 km for Scenarios 1 to 4). This could result in exclusion of other users such as vessels used by the mining and petroleum industries. The exclusion zone would probably be temporary, as significant weathering is predicted to occur within a few days of a worst-case scenario spill, therefore, physical displacement of vessels or impacts to other oil and gas operators is unlikely to be a significant impact. Modelling did not predict that surface hydrocarbons would reach any shoreline where significant industry occurs, therefore, there will be no impacts to these areas (e.g. Broome, Karratha, Dampier).

Changes to the functions, interests or activities of other users – aboriginal and indigenous heritage

Aboriginal heritage has the potential to be impacted from an unplanned hydrocarbon release through direct contact with heritage sites and impacts to Indigenous fishing activities. Although no known sites of significant Aboriginal heritage have been identified within the Project Area or EMBA, modelling indicated that localised shoreline contact above thresholds could occur at the Bardi Jawi, Uunguu and Dambimangari Indigenous Protected Areas on the Kimberley Coast at probabilities of 1-2% (Scenario 1 only). As discussed in impacts to shoreline habitats, no dissolved, entrained or floating hydrocarbons were predicted to reach these areas and contact was highly localised with maximum accumulated volumes of between 8 and 14 m^3. Furthermore, the minimum time to contact was 98 days, meaning hydrocarbons would be significantly weathered and unlikely to reach the receptor at the modelled volumes. Given this and the initial low likelihood of a spill occurring, no significant impacts are predicted to these protected areas.

Although no designated traditional fisheries have been identified, it is recognised that Indigenous communities' fish in shallow coastal and nearshore waters of the Kimberley coastline and, therefore, may be potentially impacted in the highly unlikely event that a hydrocarbon spill was to reach the coastline in significant quantities. Given no contact is predicted by floating, entrained and dissolved hydrocarbons and only minimal volumes of shoreline accumulation are predicted, no significant impacts to indigenous fishing are expected.

In addition, traditional Indonesia fishermen visiting Scott Reef and Seringapatam Reef as part of the MOU 74 provisions may be impacted in the highly unlikely event of a spill within the Browse Development Area, potentially contaminating and restricting access to their traditional fishing grounds. However, the extent of impacts will depend on exposure concentration, duration and degree of weathering of the hydrocarbons.

Marine archaeology and other cultural heritage

Change in heritage values

Marine archaeology sites such as historic shipwrecks have the potential to be impacted from an unplanned hydrocarbon release through direct contact with hydrocarbons resulting in toxicity impacts to marine life that shelter in and around these wrecks. The consequences of such hydrocarbon exposure may include all or some of the following: large fish species moving away and/or resident fish species and sessile benthos (such as hard corals) exhibiting sub-lethal and lethal impacts (which may range from physiological issues to mortality).

Within the EMBA a number of places are designated National and Commonwealth heritage places. These places are also covered by other designations such as marine parks, and listed shipwrecks. Potential impacts have, therefore been discussed in the sections above.

6.3.21.6 Cumulative Impacts

The risk of cumulative impact of hydrocarbons spills from other development activities within the Browse Basin is low, as large scale events, although they could occur, are extremely rare. Titleholders undertaking petroleum activities are required to have in place an approved OPEP detailing its oil spill response. These OPEPs are backed up by State and national response plans.

6.3.21.7 Prevention and response

In order to prevent a potential unplanned release of hydrocarbons, the following management measures will be put in place:

Drilling and completion activities

- During drilling, proven systems and procedures will be employed. These will be applied and supervised by highly competent and experienced personnel. The industry is also highly regulated.
- Drilling and completion activities will only be undertaken when metocean conditions are deemed suitable for safe operations.
- Reservoirs will be isolated from the surface by a minimum of two independent and verifiable barriers. The configuration of isolation barriers during the drilling phase typically includes:
  - Overbalanced hydrostatic pressure maintained on the reservoir via the drilling fluids.
  - Seabed BOPs which can be activated to “shut in” the well in the event that well control via overbalanced drilling fluids is lost.
- A 500 m petroleum safety zone will be implemented around the MODU.
- Relief well planning will be outlined in the OPEP.
- Accepted Safety Case for MODU.

Commissioning, operational and IMR activities

- Testing will be undertaken prior to commissioning to confirm integrity of SURF and BTL system.
- IMR activities to manage integrity of subsea systems will occur throughout operations.
- The configuration of reservoir isolation barriers during the operations phase typically includes:
  - production tubing from the reservoir to valving on the subsea tree
  - cemented casing and associated valving on the subsea tree, plus a production packer to isolate the annulus between the casing and production tubing from the reservoir
  - a Surface Controlled Subsurface Safety Valve (SCSSV) fitted on all production wells.
- the wells, subsea system and FPSO facilities will use corrosion resistant materials, where applicable and be designed to protect against integrity threats (e.g. corrosion, impact, erosion, low temperature embrittlement).
- Wellhead valve design and configuration will allow safe operation and control of the well.
- FPSO facilities will be designed to include compartmentalised condensate storage.
- FPSO facilities are assessed against one in 10,000-year return period weather conditions to mitigate risk of extreme weather conditions.
- FPSO facilities will include double sided hull design to minimise risk of hydrocarbon release in the event of a collision.
- 500 m petroleum safety zones will be maintained at the FPSO facilities.
- Design codes and material specifications for all risers and flowlines will be compliant with the relevant Australian and international standards.
- SURF and BTL monitoring will be undertaken including:
  - monitoring of corrosion protection system
  - periodic integrity inspections in line with risk-based inspection outcomes.
- Export trunkline volumes will be able to be isolated to prevent an ongoing fire impacting the FPSO
- accepted Safety Case for FPSOs.

Offloading and refuelling activities during drilling and operations

- Condensate offtake hoses will be fitted with ‘dry break’ or ‘breakaway’ couplings.
- Scuppers and save-alls (receptacles or enclosures to contain minor leakages around machinery), including those around tank vents, will be in place before commencement of refuelling activities.
- The diesel refuelling hose inventory will be drained before disconnection.
- The diesel refuelling station will be isolated and equipment stowed when not in use.
- Offloading and refuelling hoses will be certified as suitable for a safe operating pressure range. The hoses and fittings will also be compatible with support vessel/condensate tanker pump pressures.
- Support vessel/condensate tanker pumps will be fitted with relief valves to allow diverting back of fluids to source in the event of excessive pressure build up in the transfer hose.
- Where practicable, refuelling of support vessels will be conducted in port.
- Diesel storage tank levels will be continuously

monitored to prevent overflow, and tank level indication and level alarms will be provided for diesel storage tanks.

- Vessels (as appropriate to vessel class) will be required to have in place a Shipboard Oil Pollution Emergency Plan (SOPEP)/ Shipboard Marine Pollution Emergency Plan (SMPEP), as required by Marine Order 91 (Marine Pollution Prevention) 2014. Offloading and refuelling will only be undertaken when metocean conditions are deemed suitable for safe operations.
- Condensate tankers will be piloted during berthing and offloading operations.
- Offloading and refuelling will be undertaken by trained personnel using defined procedures.
- Responsibilities and accountabilities will be defined for hydrocarbon spill response and notifications to Woodside and relevant authorities.
- A loading plan (volume to be transferred) will be agreed between the supply point (vessel) and the delivery point, and a pre-load checklist completed.
- Transfer equipment and emergency shutdown functions will be checked immediately prior to commencement of offtake.
- The diesel transfer pumps emergency shutdown system onboard condensate tankers will be tested at the commencement of transfer.
- Communication (visual and/or radio) between the support vessel/condensate tanker will be maintained throughout refuelling and offloading operations.

Spill response techniques

In the event of a spill, Woodside will respond in accordance with the Environment Plans and OPEPs specifically developed for the proposed Browse to NWS Project, which will be not inconsistent with the *National Plan for Maritime Environmental Emergencies 2019*. The Environment Plans and OPEPs will detail the spill response and mitigation measures adopted by Woodside following the rigorous risk assessment of a range of spill response strategies available. These will include strategies to limit the volume of hydrocarbons being released to the marine environment and strategies to reduce the volume of hydrocarbons reaching sensitive receptors.

A comprehensive Oil Spill Preparedness and Response Mitigation Assessment (OSPRMA) will be undertaken to evaluate and determine which techniques may be incorporated into a Browse to NWS Project spill response. This OSPRMA will use the detailed environmental assessment in the EP, including the identified environmental values and sensitivities, to conduct a Net Environmental Benefit Analysis (NEBA).

The NEBA is a systematic process undertaken during both planning and response that supports the assessment and selection of response techniques to manage and reduce the overall impact of an incident. The IPIECA/IOGP good practice Spill Impact Mitigation Assessment (SIMA) methodology is adopted to undertake the NEBA. The NEBA considers the potential feasibility and effectiveness of various techniques in monitoring, treating and/or removing spilled materials. It also assists in identifying and evaluating any subsequent impacts that may be generated from the adopted response actions and which require further measures.

A NEBA is undertaken as part of the development of the OSRPRMA, using simulated oil spill modelling scenarios. Feasibility and effectiveness of the following response techniques, together with the potential exposure of environmental receptors, are considered by assessing this modelling scenario data:

- **Monitoring and evaluation of a hydrocarbon spill** includes Operational Monitoring methods that may be activated:
  - satellite tracking drifter buoy(s)
  - aerial monitoring including use of UAVs where feasible
  - satellite radar imagery
  - water quality monitoring
  - shoreline assessment: pre-emptive assessment as well as clean-up assessment
  - modelling:
    - ADIOS 2 – a hydrocarbon model that estimates the expected characteristics and behaviour of hydrocarbons spilled into the marine environment.
    - trajectory modelling – Woodside has access to both an in-house rapid modelling tool and 24/7 scenario-specific modelling capabilities.
- **Activation of a Subsea First Response Toolkit (SFRT)**, maintained by AMOSC in a constant state of readiness. The SFRT provides the following capability:
  - pressure injection to close the BOPs
  - preparing a subsea wellhead for a capping stack including removal of damaged/obstructing equipment
  - injecting dispersant subsea (including a supporting stockpile of dispersant).
- **Deployment of a well capping stack**, to be installed on the subsea well where feasible and safe to do so.
- **Drilling of a relief well** to kill the well.
- **Application of dispersants:** Dispersion of hydrocarbons into the water column reduces the volume on the ocean surface, which then reduces the potential for direct impact on emergent receptors. Dispersants break hydrocarbons down into smaller droplets which are rapidly diluted into

the water column, aiding the process of natural dispersion and accelerating biodegradation. It can also reduce surface volatile or organic compounds when dispersants are applied subsea.

Many light hydrocarbons, including Torosa condensate, may not be amenable to dispersants, as the droplet sizes are already below the point that can be achieved with dispersants. In Australia, AMSA maintains a list of approved Oil Spill Control Agents (OSCA) that includes dispersants. In the highly unlikely event of an unplanned hydrocarbon spill from the Browse to NWS Project, dispersant use would only be considered for use in areas that are within the dispersant 'Zone of Application' (ZoA) defined in the Browse Environment Plans and OPEPs. In defining the ZoA for dispersant use, Woodside would expressly prohibit the use of dispersants within areas such as Scott Reef.

The decision to apply dispersants during a spill would still be subject to a rigorous risk assessment, including revalidation of the NEBA undertaken in the OSPRMA using modelling and monitoring of actual data from the spill. If dispersant is assessed to be an appropriate technique, only OSCA dispersants approved by the regulator will be utilised. They will only be applied to surface hydrocarbons where appropriate concentration thresholds are present, and continuous monitoring of the dispersed oil plume will be undertaken to ensure ongoing effectiveness. Dispersant application will cease when operational monitoring shows that its use is no longer effective.

- **Containment and recovery:** Physical containment and removal of hydrocarbons from the marine environment minimises damage to sensitive resources. This technique may be triggered when monitoring indicates that a floating hydrocarbon threshold has been reached, making it a potentially effective technique. Some limitations also include current and wind conditions, which may inhibit effectiveness.
- **Protection and deflection:** Use of booms to create physical barriers to separate hydrocarbons from sensitive resources. This technique can be effective on some hydrocarbons where surface accumulation exceeds thresholds required. Browse hydrocarbons will be assessed against viability for using protection and deflection.
- **Shoreline clean-up:** Recovery of hydrocarbons accumulated on shorelines to minimise environmental damage. Typical techniques that may be used for shoreline clean-up include:
  - nearshore booming and skimming
  - use of sorbents
  - manual clean-up
  - waste collection facilities – temporary storage or vessels with waste tanks.
- **In-situ burning:** A NEBA will consider in-situ burning to determine its suitability as a response technique for Browse and to support identifying any restrictions that may apply to its use, if it is identified as a suitable response technique. However, potential long-term damage to the subsea ecology due to particulates as a result of in-situ burning is not well understood scientifically and its benefits versus risks have not been proven. Although this remains a potential technique, it is unlikely to be used for the Browse to NWS Project.
- **Oiled wildlife response:** Undertaken to minimise impacts on at-risk wildlife populations, oiled wildlife response activities would be carried out in accordance with the Western Australian Oiled *Wildlife Response Plan (WA OWRP)*, to ensure it is conducted in accordance with legislative requirements, and additionally following Woodside's *Oiled Wildlife Response Operational Plan*. Woodside has access to oiled wildlife response kits from AMOSC and OSRL and trained personnel via AMOSC, OSRL, Woodside and Sea Alarm.
- **Scientific monitoring:** Undertaken to quantify and monitor impacts and recovery to a range of environmental receptors, such as (but not limited to) water quality, sediment quality, benthic primary producers and fauna. Scientific monitoring will also be used to inform response techniques and longer term recovery programs. The types of scientific monitoring needed would be assessed as part of the OSPRMA. Scientific monitoring would be carried in accordance with Woodside's Scientific Monitoring Program. Woodside has access to a range of equipment and trained personnel via standby contract with selected environmental consultancies. Each EP and OPEP will include an assessment of any additional risks and impacts that may be generated from the adopted response techniques, including further reduction and mitigation measures. From previous assessments, Woodside has identified a series of treatment measures to mitigate further potential impacts and risks generated from implementing response techniques. An indicative list of these measures are described below.

Vessel operations and access in the nearshore environment

- Booms will be monitored and maintained to ensure trapped fauna are released as early as possible, with containment and recovery activities only occurring in daylight hours.
- If vessels are required for accessing areas, anchoring locations will be selected to minimise disturbance to benthic primary producer habitats.
- Shallow draft vessels will be used to access remote shorelines to minimise the impacts associated with seabed disturbance.

Dispersant

- Surface dispersant will only be applied within the approved zone and to hydrocarbons at the appropriate concentration thresholds.
- Continuous monitoring of dispersed oil plume will be undertaken to monitor effectiveness.
- Regulator-approved dispersants will be prioritised for surface and subsea use.

Presence of personnel on the shoreline

- Oversight will be provided by trained personnel who are aware of the risks.
- Trained unit leaders will brief personnel of the risks prior to operations.
- Shoreline access routes (foot, car, vessel and helicopter) with the least environmental impact will be selected by trained specialists.
- Vehicular access will be restricted on dunes, turtle nesting beaches and in mangroves.

Waste generation

- All shorelines will be zoned and marked before clean-up operations commence to prevent secondary contamination and minimise the mixing of clean and oiled materials.
- Removal of vegetation will be limited to moderately or heavily oiled vegetation.

Additional stress or injury caused to wildlife

- Operations will be conducted with advice from the Department of Biodiversity, Conservation and Attractions (DBCA) Oiled Wildlife Advisor and in accordance with the WA OWRP.

Review of major incidents

Woodside periodcally reviews major incidents and updates (as appropriate) practices, emergency response and oil spill contingency plans to ensure that the systems in place are comprehensive and appropriate to design for, maintain and manage primary and secondary well control. Woodside also evaluates and improves the adequacy of procedural controls such as management of change, engineering assurance and competency assessments of personnel to ensure that the mechanisms outlined above are correctly and consistently applied.

6.3.21.8 Impact and Risk Assessment Summary and Acceptability Assessment

A summary of the risk assessments for the highly unlikely event of an unplanned release of hydrocarbons is provided in **Table 6-162**.Assessment has been given for the worst-case predicted consequences from any unplanned hydrocarbon release, including modelled Scenarios 1 through 4.

These tables provide the environmental objectives relevant to each potentially impacted receptor, as well as the risk rating for unplanned events and incidents.

For unplanned incidents and events, the environment objective is predicted to be achieved and the risk deemed acceptable where the risk rating has been assessment as Low, or where the risk rating has been assessed as Moderate or High, with the risk likelihood of the event occurring assessed as remote or highly unlikely.

The final acceptability assessment is provided in Table 6-163.

Table 6-162 Risk assessment summary and adopted controls – Unplanned Hydrocarbon Releases (Modelled Scenarios 1 to 4) (Hold: added scenario 4)

Receptor	Risk Event	Environmental objective	Adopted controls	Scenario	Consequence	Likelihood	Risk Rating
Marine sediments (medium value (open waters))	Unplanned hydrocarbon release leading to: + Change in sediment quality + Change in water quality + Injury or mortality to fauna + changes to the functions, interests or activities of other users + change in heritage values.	**Objective 1:** To not result in a substantial change in sediment quality which may adversely impact on biodiversity, ecological integrity, social amenity or human health. **Objective 2:** To not result in persistent organic chemicals, heavy metals, or other potentially harmful chemicals accumulating in the marine environment such that biodiversity, ecological integrity, social amenity or human health may be adversely affected.	Refer to Section 6.3.21.7 for details of the planned preventive measures and approach to hydrocarbon spill response.	Scenario 1: Well loss of containment	Catastrophic	Highly unlikely	High (A1)
				Scenario 2: Cargo tank rupture	Major		Moderate (B1)
				Scenario 3: Vessel offtake system failure	Minor		Moderate (D1)
				Scenario 4: Vessel fuel tank rupture	Moderate		Moderate (C1)
Water quality (medium value (open waters))		**Objective 3:** To not result in a substantial change in water quality which may adversely impact on biodiversity, ecological integrity, social amenity or human health.		Scenario 1: Well loss of containment	Catastrophic	Highly unlikely	High (A1)
				Scenario 2: Cargo tank rupture	Major		Moderate (B1)
				Scenario 3: Vessel offtake system failure	Minor		Moderate (D1)
				Scenario 4: Vessel fuel tank rupture	Moderate		Moderate (C1)
Plankton communities (medium value (open water))		**Objective 7:** To not have a substantial adverse effect on a population of plankton including its lifecycle and spatial distribution.		Scenario 1: Well loss of containment	Moderate	Highly unlikely	Moderate (C1)
				Scenario 2: Cargo tank rupture	Moderate		Moderate (C1)
				Scenario 3: Vessel offtake system failure	Minor		Moderate (D1)
				Scenario 4: Vessel fuel tank rupture	Minor		Moderate (D1)
Shallow water benthic communities and habitats (<75 m depth)		**Objective 10:** To avoid changes beyond natural variation in ecosystem processes, biodiversity, abundance and biomass of marine life or in the quality of water, sediment and biota that form part of the Scott Reef shallow water benthic habitat (<75 m water depth).		Scenario 1: Well loss of containment	Catastrophic	Highly unlikely	High (A1)
				Scenario 2: Cargo tank rupture	Catastrophic		High (A1)
				Scenario 3: Vessel offtake system failure	Moderate		Moderate (C1)
				Scenario 4: Vessel fuel tank rupture	Major		Moderate (B1)
Deep water benthic communities and habitats (>75 m depth) – (medium value)		**Objective 6:** To not modify, destroy, fragment, isolate or disturb an important or substantial area of habitat such that an adverse impact on marine ecosystem functioning or integrity results.		Scenario 1: Well loss of containment	Catastrophic	Highly unlikely	High (A1)
				Scenario 2: Cargo tank rupture	Major		Moderate (B1)
				Scenario 3: Vessel offtake system failure	Minor		Moderate (D1)
				Scenario 4: Vessel fuel tank rupture	Moderate		Moderate (C1)

Receptor	Risk Event	Environmental objective	Adopted controls	Scenario	Consequence	Likelihood	Risk Rating
Seabirds and migratory shorebirds (high value species)		**Objective 11:** To not have a substantial adverse effect on a population of seabirds or migratory shorebirds, or the spatial distribution of the population. **Objective 12:** To not substantially modify, destroy or isolate an area of important habitat for a threatened or migratory species. **Objective 13:** To not seriously disrupt the lifecycle (breeding, feeding, migration or resting behaviour) of an ecologically significant proportion of the population of a threatened or migratory species. **Objective 14:** To not have a substantial adverse effect on a population of fish, or the spatial distribution of the population. **Objective 15:** To not have a substantial adverse effect on a population of marine mammals, or the spatial distribution of the population. **Objective 16:** To not have a substantial adverse effect on a population of marine reptiles, or the spatial distribution of the population.		Scenario 1: Well loss of containment	Catastrophic	Highly unlikely	High (A1)
				Scenario 2: Cargo tank rupture	Catastrophic		High (A1)
				Scenario 3: Vessel offtake system failure	Moderate		Moderate (C1)
				Scenario 4: Vessel fuel tank rupture	Major		Moderate (B1)
Fish (high value species)				Scenario 1: Well loss of containment	Catastrophic	Highly unlikely	High (A1)
				Scenario 2: Cargo tank rupture	Catastrophic		High (A1)
				Scenario 3: Vessel offtake system failure	Moderate		Moderate (C1)
				Scenario 4: Vessel fuel tank rupture	Major		Moderate (B1)
Marine mammals (high value species)				Scenario 1: Well loss of containment	Catastrophic	Highly unlikely	High (A1)
				Scenario 2: Cargo tank rupture	Catastrophic		High (A1)
				Scenario 3: Vessel offtake system failure	Moderate		Moderate (C1)
				Scenario 4: Vessel fuel tank rupture	Major		Moderate (B1)
Marine reptiles (high value species)				Scenario 1: Well loss of containment	Catastrophic	Highly unlikely	High (A1)
				Scenario 2: Cargo tank rupture	Catastrophic		High (A1)
				Scenario 3: Vessel offtake system failure	Moderate		Moderate (C1)
				Scenario 4: Vessel fuel tank rupture	Major		Moderate (B1)
KEFs (medium value)		**Objective 17:** To not modify, destroy, fragment, isolate or disturb an important or substantial area of habitat such that an adverse impact on marine ecosystem functioning or integrity in an area defined as a Key Ecological Feature.		Scenario 1: Well loss of containment	Moderate	Highly unlikely	Moderate (C1)
				Scenario 2: Cargo tank rupture	Minor		Moderate (D1)
				Scenario 3: Vessel offtake system failure	No lasting effect		Low (F1)
				Scenario 4: Vessel fuel tank rupture	Slight		Low (E1)
Australian marine parks (medium value (multiple use zones))		**Objective 18:** To not modify, destroy, fragment, isolate or disturb an important or substantial area of habitat such that an adverse impact on marine ecosystem functioning or integrity of a Protected Place.		Scenario 1: Well loss of containment	Catastrophic	Highly unlikely	High (A1)
				Scenario 2: Cargo tank rupture	Catastrophic		High (A1)
				Scenario 3: Vessel offtake system failure	Moderate		Moderate (C1)
				Scenario 4: Vessel fuel tank rupture	Major		Moderate (B1)
State marine parks and nature reserves and other protected places (high value)		**Objective 18:** To not modify, destroy, fragment, isolate or disturb an important or substantial area of habitat such that an adverse impact on marine ecosystem functioning or integrity of a Protected Place.		Scenario 1: Well loss of containment	Catastrophic	Highly unlikely	High (A1)
				Scenario 2: Cargo tank rupture	Catastrophic		High (A1)
				Scenario 3: Vessel offtake system failure	Moderate		Moderate (C1)
				Scenario 4: Vessel fuel tank rupture	Major		Moderate (B1)

Receptor	Risk Event	Environmental objective	Adopted controls	Scenario	Consequence	Likelihood	Risk Rating
State and Commonwealth managed fisheries (high value marine users)		**Objective 20:** To not have a substantial adverse effect on the sustainability of commercial fishing. **Objective 21:** To not interfere with other marine users to a greater extent than is described in the EIS/ERD.		Scenario 1: Well loss of containment	Catastrophic	Highly unlikely	High (A1)
				Scenario 2: Cargo tank rupture	Catastrophic		High (A1)
				Scenario 3: Vessel offtake system failure	Moderate		Moderate (C1)
				Scenario 4: Vessel fuel tank rupture	Major		Moderate (B1)
Other users including tourism and recreation and scientific studies (high value users)		**Objective 21:** To not interfere with other marine users to a greater extent than is described in the EIS/ERD.		Scenario 1: Well loss of containment	Major	Highly unlikely	Moderate (B1)
				Scenario 2: Cargo tank rupture	Moderate		Moderate (C1)
				Scenario 3: Vessel offtake system failure	Slight		Low (E1)
				Scenario 4: Vessel fuel tank rupture	Minor		Moderate (D1)
Shipping (Medium/ high value users)		**Objective 21:** To not interfere with other marine users to a greater extent than is described in the EIS/ERD.		Scenario 1: Well loss of containment	Major	Highly unlikely	Moderate (B1)
				Scenario 2: Cargo tank rupture	Moderate		Moderate (C1)
				Scenario 3: Vessel offtake system failure	Slight		Low (E1)
				Scenario 4: Vessel fuel tank rupture	Minor		Moderate (D1)
Industry (low value)		**Objective 21:** To not interfere with other marine users to a greater extent than is described in the EIS/ERD.		Scenario 1: Well loss of containment	Slight	Highly unlikely	Low (E1)
				Scenario 2: Cargo tank rupture	No lasting effect		Low (F1)
				Scenario 3: Vessel offtake system failure	No lasting effect		Low (F1)
				Scenario 4: Vessel fuel tank rupture	No lasting effect		Low (F1)
Aboriginal and indigenous heritage (high value)		**Objective 19:** To not have a substantial adverse impact on heritage value.		Scenario 1: Well loss of containment	Minor	Highly unlikely	Moderate (D1)
				Scenario 2: Cargo tank rupture	Slight		Low (E1)
				Scenario 3: Vessel offtake system failure	Slight		Low (E1)
				Scenario 4: Vessel fuel tank rupture	Slight		Low (E1)
Marine archaeology (high value)		**Objective 19:** To not have a substantial adverse impact on heritage value.		Scenario 1: Well loss of containment	Minor	Highly unlikely	Moderate (D1)
				Scenario 2: Cargo tank rupture	Slight		Low (E1)
				Scenario 3: Vessel offtake system failure	Slight		Low (E1)
				Scenario 4: Vessel fuel tank rupture	Slight		Low (E1)

Table 6-163 Acceptability assessment – unplanned hydrocarbon releases

Acceptability Assessment

Confidence in assessment

Woodside has a high level of certainty with respect to the risks and consequences of an unplanned hydrocarbon release as:

- Quantitative hydrocarbon spill modelling utilising established methods has been undertaken of the worst-case credible spill scenarios.
- The worst-case impact magnitudes to receptors, although significant, are based on worst-case scenarios which are highly unlikely to occur given the controls implemented and, therefore, within the applicable standards.
- As an experienced and reputable operator, Woodside has a proven track record with respect to spill prevention and response preparedness.
- In the event of a spill, Woodside will respond in accordance with the Environment Plans and OPEPs specifically developed for the proposed Browse to NWS Project, which will be not inconsistent with the *National Plan for Maritime Environmental Emergencies 2019*. The Environment Plans and OPEPs will detail the spill response and mitigation measures adopted by Woodside following the rigorous risk assessment of a range of spill response strategies available.

Principles of ESD

There are no planned release of hydrocarbons to the environment. The likelihood of an unplanned hydrocarbon release is considered highly unlikely, particularly given the stringent controls in place.

With the application of the proposed controls it is predicted that the nominated environmental objective for each potentially impacted receptor will be achieved. As such, it is considered that the principles of ESD will be met.

Conclusion: Acceptable

Significant impacts as defined by the MNES Significant Impact Guidelines

Listed threated species and ecological communities/listed migratory species

As described in **Table 6-162**, the risk of an unplanned hydrocarbon release presents a Moderate to High risk to all listed threatened and migratory species (depending on the scenario).

These risk ratings are driven by the potential Moderate to Catastrophic consequence (depending on the scenario) where regional impacts affecting species at a population level could occur. It should be noted, however, that with the implementation of the proposed controls it is highly unlikely that such an event would occur. As such, no significant impacts to listed threated or migratory species (as defined by the Significant Impact Guidelines (**Table 6-5**)) are predicted.

Commonwealth marine environment

As described in **Table 6-162**, the risk of an unplanned hydrocarbon release presents a Moderate to High risk to all ecological receptors (depending on the scenario) and a Low to High risk to other marine users (depending on the user and the scenario). As above, these risk ratings are driven by the potential Moderate to Catastrophic consequence (depending on the scenario) where regional impacts affecting the marine environment could occur. As above, with the implementation of the proposed controls, it is highly unlikely that such an event would occur. As such, no significant impacts to the Commonwealth marine environment (as defined by the Significant Impact Guidelines (**Table 6-5**)) are predicted.

National Heritage Places

Even the highly unlikely event of an unplanned hydrocarbon release, no impact to National Heritage Places would be expected.

Conclusion: Acceptable

Acceptability Assessment

WA EPA Environmental Objectives

An assessment of the risk presented in relation to unplanned hydrocarbon release against the WA EPA Objectives is presented in the State Proposal ERD (**Chapter 10, Appendix B**).

Marine environmental quality

As described in **Table 6-162**, the risk of an unplanned hydrocarbon release presents a Moderate to High risk to sediment quality and water quality and a Moderate risk to plankton (depending on the scenario). As above, these risk ratings are driven by the potential Moderate to Catastrophic consequence (depending on the scenario) where regional impacts affecting the marine environmental quality both within the State Proposal Area and other State waters including adjacent to the mainland could occur. As above, with the implementation of the proposed controls, it is highly unlikely that such an event would occur. Given this, it is considered that with the application of the proposed controls, the nominated environmental objectives for these receptors will be achieved, and the WA EPA environmental objective "*To maintain the quality of water, sediment and biota so that environmental values are protected*" will be achieved for the State Proposal.

Benthic communities and habitats

As described in **Table 6-162**, the risk of an unplanned hydrocarbon release presents a Moderate to High risk to benthic habitats including regional shallow water benthic habitats. As above, these risk ratings are driven by the potential Minor to Catastrophic consequence (depending on the scenario) where regional impacts affecting benthic communities and habitats both within the State Proposal Area and other State waters including adjacent to the mainland could occur. As above, with the implementation of the proposed controls, it is highly unlikely that such an event would occur. Given this, it is considered that with the application of the proposed controls, the nominated environmental objectives for these receptors will be achieved, and the WA EPA environmental objective "*To protect benthic communities and habitats so that biological diversity and ecological integrity are maintained*" will be achieved for the State Proposal.

Marine fauna

As described in **Table 6-162**, the risk of an unplanned hydrocarbon release presents a Moderate to High risk to marine fauna. As above, these risk ratings are driven by the potential Moderate to Catastrophic consequence (depending on the scenario) where regional impacts affecting the marine fauna within the State Proposal Area and other State waters including adjacent to the mainland could occur. As above, with the implementation of the proposed controls, it is highly unlikely that such an event would occur. Given this, it is considered that with the application of the proposed controls, the nominated environmental objectives for these receptors will be achieved, and the WA EPA environmental objective "*To protect marine fauna so that biological diversity and ecological integrity are maintained*" will be achieved for the State Proposal.

Conclusion: Acceptable

External context

To date, there have been no specific matters raised by stakeholders regarding hydrocarbon spills in relation to the proposed Browse to NWS Project.

Conclusion: Acceptable

Internal context

Hydrocarbon spill prevention and response will be managed in accordance with regulatory requirements, including Safety Cases, EPs, OPEPs and a Well Operations Management Plan to manage credible spill risks, capability and response, which require acceptance by NOPSEMA. In addition, vessels will have a valid and appropriate SOPEP and/or SMPEP.

Conclusion: Acceptable

Acceptability Assessment

Other requirements

EPBC Act recovery and conservation plans and advices

As detailed in Table 6-159, the proposed activities are considered to be not inconsistent with the objectives and actions of:

- Wildlife Conservation Plan for Migratory Shorebirds (Commonwealth of Australia, 2015a)
- Conservation advice *Rhincodon typus* whale shark (Threatened Species Scientific Committee, 2015a)
- Recovery Plan for Marine Turtles in Australia (2017-2027) (Commonwealth of Australia, 2017a)
- Conservation Management plan for the Blue Whale (Commonwealth of Australia, 2015c)
- Conservation advice *Megaptera novaeangliae*, Humpback Whale (Threatened Species Scientific Committee, 2015b)
- Conservation advice *Balaenoptera borealis*, Sei Whale (Threatened Species Scientific Committee, 2015c)
- Conservation advice *Balaenoptera physalus*, Fin Whale (Threatened Species Scientific Committee, 2015d)

KEFs

As detailed in Table 6-160, the proposed activities are not predicted to materially increase existing relevant pressures on the conservation values of KEFs.

AMPs

As detailed in Table 6-161, proposed activities are considered to be within the objectives of AMPs.

Other protected places

No impacts are expected to occur to the to the values of the Scott Reef and Surrounds or the Mermaid Reef – Rowley Shoals Commonwealth Heritage Places.

Conclusion: Acceptable

6.4 Social and Economic Considerations

Introduction

Assessment under the EPBC Act and EP Act requires consideration of the social, economic, aesthetic and cultural aspects of the physical and biological environment. Under the EPBC Act, the Minister must also consider economic and social matters in deciding whether to approve an action and what conditions to impose.

6.4.1 Social Impact Assessment

To inform the assessment of social matters and potentially to identify any social aspects relevant to stakeholders in relation to the physical environment, in 2018, Woodside commissioned a SIA for the proposed Browse to NWS Project to identify potential impacts and opportunities and provide recommendations for management and mitigation while also ensuring the opportunities presented are maximised.

The Browse to NWS Project SIA study area incorporated the community of Broome, the Dampier Peninsula, the wider Kimberley region and the State of Western Australia (Advisian, 2019).

Broome and the Dampier Peninsula are considered most likely to be affected by the potential social benefits and impacts due to Broome being considered the potential primary supply chain and logistic locations for the proposed Browse to NWS Project. The SIA addressed socio-economic impacts and risks related directly to offshore activities associated with the proposed Browse to NWS Project. These impacts and risks are addressed for each relevant aspect in Section 6.3.

This section summaries the results of the SIA to assess the potential social impacts and opportunities which may arise from the proposed Browse to NWS Project, including potential changes resulting from the construction and operation phases.

6.4.2 Method

Potential social impacts and opportunities on Broome and the Dampier Peninsula communities arising from the proposed Browse to NWS Project were assessed in terms of how potential Browse to NWS Project activities may interact with communities and stakeholders that are likely to be affected.

At the direction of Woodside, the SIA methodology included targeted stakeholder engagement. Key stakeholders were consulted and provided input into the identification and assessment of impacts as well as the understanding of local and regional dynamics. Refer to Chapter 4 for further detail on stakeholders.

Identified impacts and opportunities were rated with a significance and ranked. This process facilitated an understanding of the overall magnitude and significance of each issue.

Following this process, mitigation and management measures to enhance opportunities and minimise potential impacts for the local communities were developed. The process sought to align measures with regional planning initiatives to maximise outcomes for communities rather than duplicate existing services or programs. They were also aligned with, or serve to enhance, Woodside's current activities in the region (Advisian, 2019).

6.4.3 Key Findings

6.4.3.1 Economic Development, Local Business and Employment Opportunities

The economic development, business and employment opportunities were the primary opportunities for local communities, particularly within Broome.

The findings of the ACIL Allen Economic Impact Assessment (further detailed in Chapter 3) suggests that the proposed Browse to NWS Project is projected to provide direct economic benefit into the Western Australian economy, as well as indirect benefits through utilisation of service and support industries. With a 44-year project lifecycle, this represents a significant opportunity to contribute to the economic development of Broome and the Kimberley more broadly.

Woodside's commitment to using Broome as the supply chain and logistics hub offers increased potential to contribute to the economy of Broome and has generated a level of excitement within the town for the potential this offers in terms of economic development, employment and skills development.

The proposed Browse to NWS Project presents Woodside with an opportunity to utilise an increased regional approach building employment opportunities and a skilled labour force. It was acknowledged that the opportunity would be incremental, and expectations should be managed through transparent engagement with communities.

The long potential project lifecycle of the proposed Browse to NWS Project presents an opportunity for Woodside to identify social investment options designed to support local capability development for a number of communities within the project impact areas, specifically Indigenous communities.

6.4.3.2 Community Amenity and Cohesion

Community amenity concerns were identified, for example, these included helicopter noise in Broome and the 'visibility' and behaviour of the workforce. Amenity related impacts will be more concentrated during construction.

As a workforce transit point for offshore and onshore developments, workforce behaviour was identified as an issue by some stakeholders.

Stakeholders emphasised that while the oil and gas industry and the tourism industry can co-exist, the 'visibility' of the oil and gas industry through poor workforce behaviour and a lot of 'high-vis' can detract from the overall amenity and lifestyle in the town. While these impacts can be significant, they are also readily mitigated.

A further attraction contributing to amenity and lifestyle in Broome is its location. However, it is this location, primarily the distance and sometimes excessive costs to travel in and out of Broome. Airfare costs also impact on residents and local businesses, particularly the tourism industry. With the exception of some seasonal direct flights from the east coast of Australia to Broome, almost all flights transit via Perth. SIA consultations revealed a concern that once construction of the proposed Browse to NWS Project begins, flights in and out of Broome, specifically to Perth, will again become excessively expensive. It should be noted expensive airfares are the result of a number of factors, and while the proposed Browse to NWS project may contribute to price increases, clear attribution for this will be difficult to quantify. Consultations did reveal that measures have been made by airlines to manage excessive flight costs for Broome residents.

6.4.3.3 Housing and Accommodation

The proposed Browse to NWS Project is likely to have minimal negative or positive impacts on the housing and accommodation market in Broome. The offshore nature of the proposed Browse to NWS Project and the small operations workforce will not see a significant increase in demand for housing and accommodation.

6.4.3.4 Population Growth

The SIA identified a desire among the Broome community for the population to grow, but in a sustained way that contributes to a vibrant community with a strong economy. Population growth could translate into economic growth and stability if this growth is sustained in the long-term. SIA findings indicate that Broome can accommodate an increase in population and there will be limited to no impact on existing service providers such as health providers, who all indicated capacity to meet increased demands.

6.4.3.5 Cultural Heritage

The impact of the proposed Browse to NWS Project on sites of cultural significance was considered in the context of the offshore nature of the project.

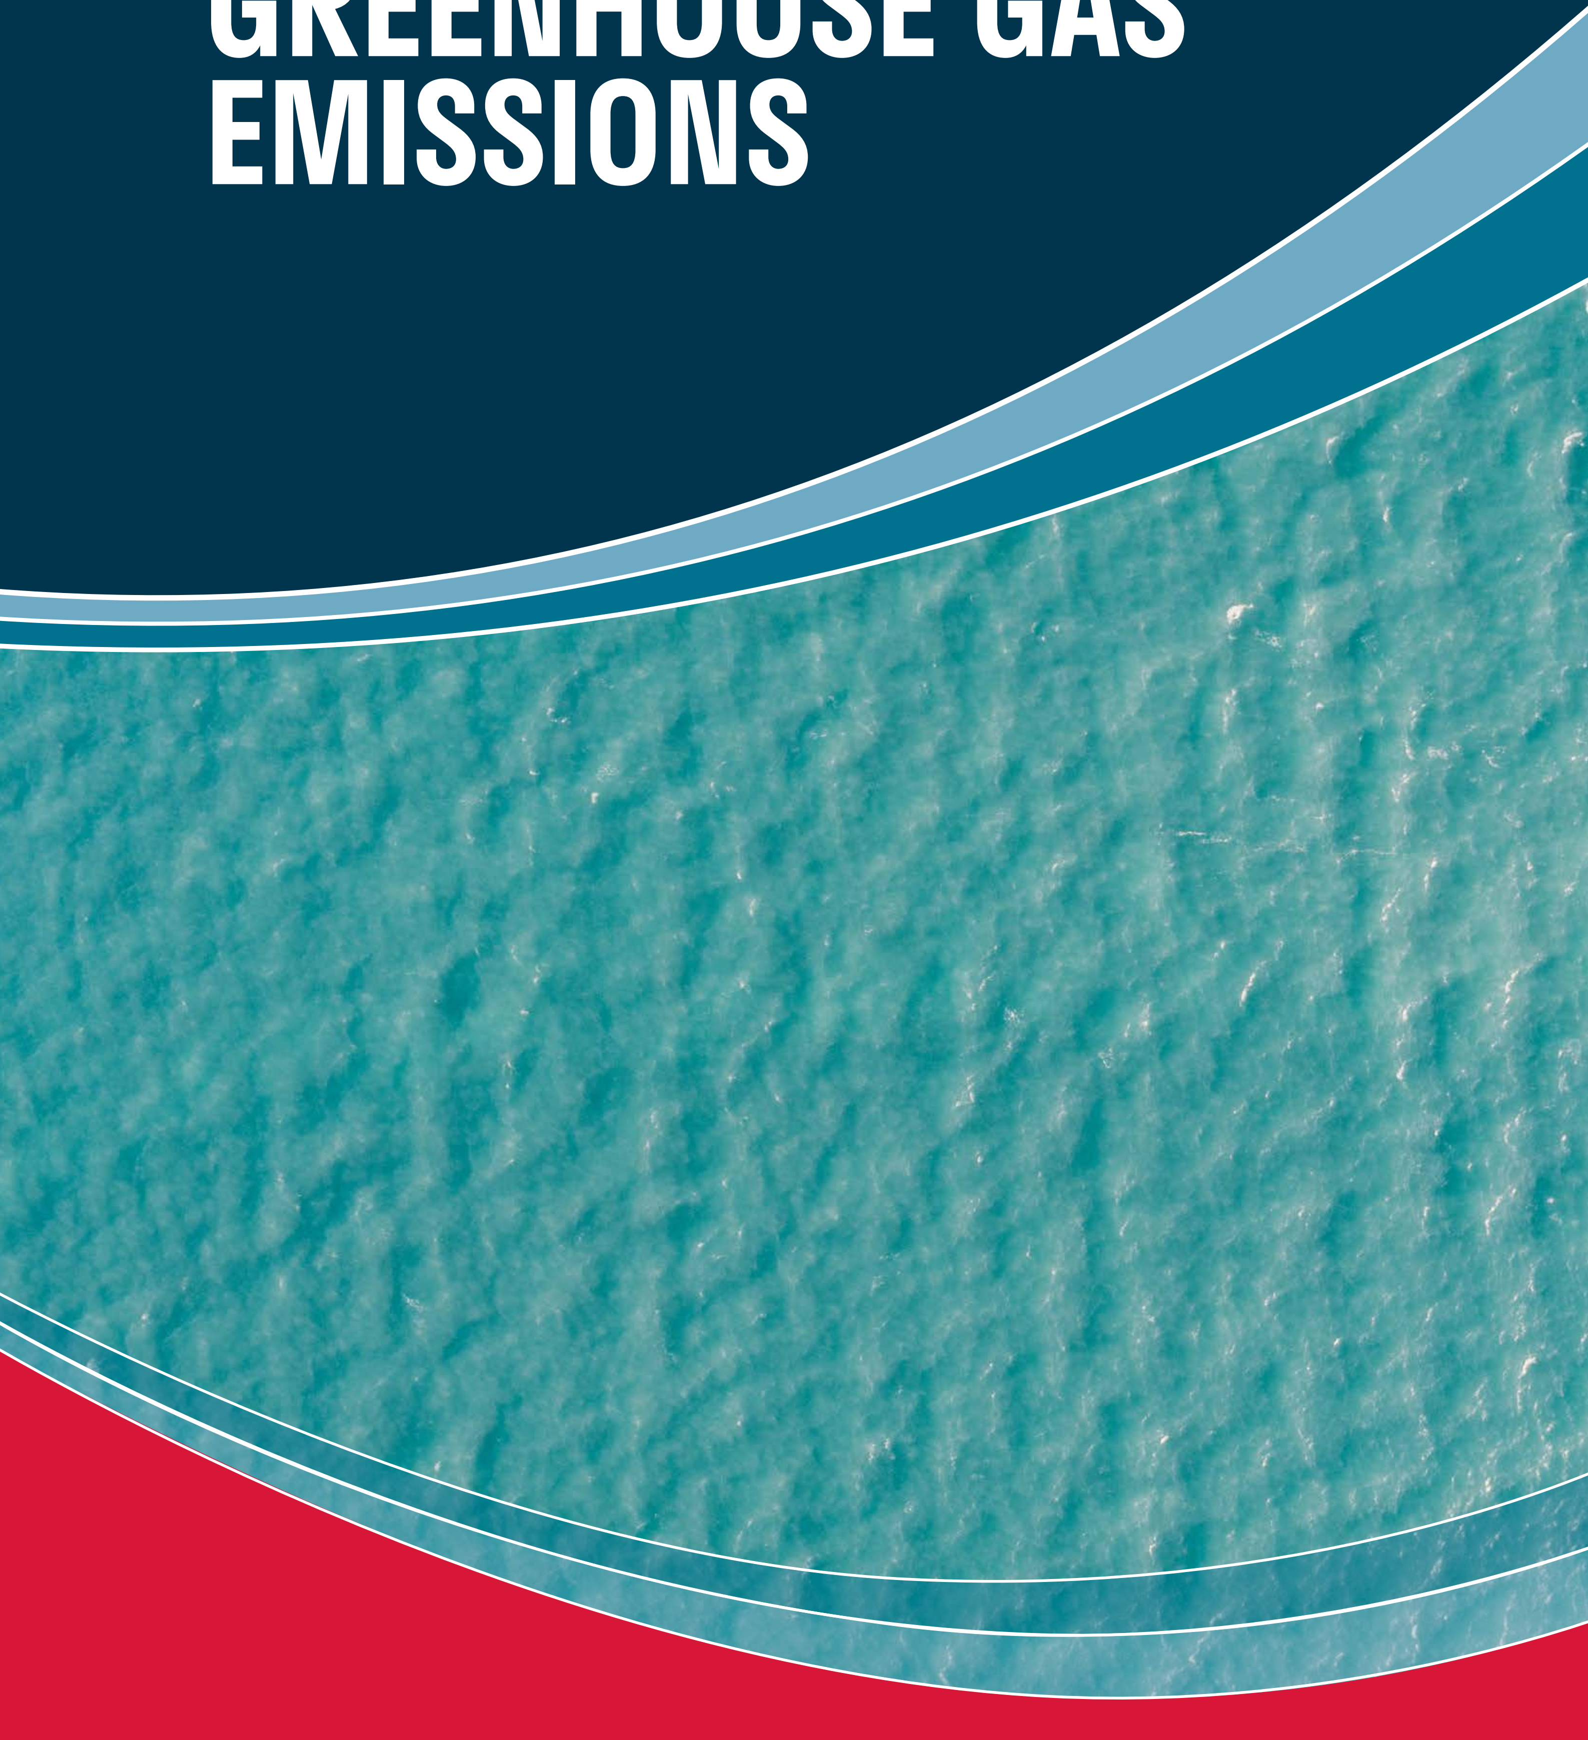
SIA consultations with Dampier Peninsula communities highlighted the strong linkage that exists between Aboriginal stakeholders and the sea, as an important food source, but also as an important cultural resource.

6.4.4 Proposed Approach to Mitigation and Management

Mitigation and management measures proposed in this assessment will be implemented through social impact management plans prepared in the usual course as part of the implementation of Woodside Management System.

CHAPTER 7

GREENHOUSE GAS EMISSIONS



Woodside

7. GREENHOUSE GAS EMISSIONS

7.1 Overview

This chapter details the assessment of greenhouse gas (GHG) emissions, including the potential impact on sensitive receptors within Australian jurisdictions and the contribution of GHG emissions from the proposed Browse to NWS Project.

GHG emissions are those that absorb infrared radiation in the atmosphere and release this energy as heat, consequently increasing global temperatures. This increase in temperature is predicted to have an adverse effect on natural ecosystems as a result of reductions in the bioclimatic range within which a given species or ecological community exists.

The main categories of human-induced activities that emit GHGs are:

- energy
- industrial processes including use of synthetic gases
- waste emissions
- agriculture
- land use, land use change and forestry.

Ecosystems which are particularly susceptible to adverse effects of climate change include alpine habitats, coral reefs, wetlands and coastal ecosystems, polar communities, tropical forests, temperate forests and arid and semi-arid environments (Department of the Environment and Energy, 2019). In Australia, the most affected ecosystems include coral reefs, alpine regions, rainforests, arid and semi-arid environments, mangroves, grasslands, temperate forests and sclerophyll forests. Future climate change (increased temperature and decreased rainfall) has the potential to have a range of impacts on ecological factors and threaten biodiversity in the Australian Mediterranean ecosystem (CSIRO, 2017).

7.2 Environment Objective

The key environmental objectives of the proposed Browse to NWS Project in relation to GHG emissions are:

- To not result in a substantial change in air quality which may adversely impact on biodiversity, ecological integrity, social amenity or human health.
- To optimise efficiencies in air emissions and reduce greenhouse emissions to acceptable levels.

7.3 Policy and Guidance

7.3.1 International Policy

The United Nations Framework Convention on Climate Change (UNFCCC) came into force in 1994 and has been ratified by 197 countries. The UNFCCC established a goal of preventing dangerous anthropogenic interference with the climate system. Subordinate treaties and agreements have been ratified by parties to the UNFCCC, including the Paris Agreement in 2015. The Paris Agreement establishes a series of targets including:

- Keeping "global average temperature to well below 2°C above pre-industrial levels and pursuing efforts to limit temperature increase to 1.5°C" (Article 2.1(a)).
- Reaching "global peaking of GHG emissions as soon as possible…achieve a balance between anthropogenic emissions by sources and removals by sinks in the second half of this century" (Article 4.1).

The ratification of the Paris Agreement under decision 1/CP.21 (UNFCCC, 2016) acknowledged that the Nationally Determined Contributions (NDCs) made by countries as commitments under the Paris Agreement were insufficient to meet the goals of the Paris Agreement. To manage this, the Paris Agreement includes a process to update, or 'ratchet-up' NDCs every 5 years.

Australia's NDC is for an absolute economy-wide emissions reduction by 2030, to be developed into an emissions budget covering the period 2021-2030 (Australia, 2015). Australia is expected to restate its NDC in 2020 and update it in 2025.

7.3.2 Commonwealth Legislation and Policy

The following key legislation relating to GHG is administered by the Clean Energy Regulator:

- *National Greenhouse & Energy Reporting Act 2007* (Cth) (NGERS) established the NGER scheme which require companies such as Woodside to report on GHG emissions, energy production and energy consumption.
- *National Greenhouse and Energy Reporting Regulations 2008* (Cth) sets out the details that establish compliance rules and procedures for administering the NGERS.

- *National Greenhouse and Energy Reporting (Measurement) Determination 2008* (Cth) sets the methods, criteria and measurement standards for calculating greenhouse gas emissions and energy data.
- *The National Greenhouse and Energy Reporting (Safeguard Mechanism) Rule 2015* (Cth) (SGM) sets out the details that establish compliance rules and procedures for administering the safeguard mechanism.

The Safeguard Mechanism (see 7.3.2 below) is one of a number of mechanisms by which Australia intends to meet its NDC. It was developed to ensure that emission reductions implemented through the Emissions Reduction Fund (ERF) are not offset or exceeded by significant GHG emissions (above 'business-as-usual levels') emanating from other industrial or economic sectors. The SGM currently applies to facilities which emit greater than 0.1 $MtCO_2$-e per annum, requiring annual covered emissions to be reported against a designated emissions 'baseline'.

In March 2019, modifications to the SGM were introduced to transition facilities from current 'reported' baselines (an absolute value based on the historical high-point of emissions) to a 'calculated' baseline (set based on production forecasts and emissions intensity). There is now an expectation that existing facilities will transition to calculated baselines within the next two years.

This change to the SGM also provides direction for future transition from calculated baselines, which are valid for a fixed period, to 'production adjusted' baselines which are annually updated in line with production.

New facilities after 1 July 2020 will be subject to a 'benchmark baseline', which is expected to be defined by the DoEE and be based on leading-practice emissions intensities (top 10% of comparable facilities).

At the time of writing, three schedules within the SGM remain unpublished. These will include the benchmark parameters, production adjusted production variables and emissions intensities and fixed production variables and emissions intensities (Schedules 1, 2 and 3 respectively). The publication of this data is intrinsic to determining a baseline emissions figure under the SGM amendments.

The Federal Government climate change policy is the Climate Solutions Package (CSP), "a $3.5 billion investment to deliver on Australia's 2030 Paris climate commitments" (DOEE, 2019). In addition to the SGM, the CSP includes a range of programs to reduce emissions, including a $A2 billion 'Climate Solutions Fund' to provide additional budget for the operational Emissions Reduction Fund, support for energy efficiency and electric vehicles, two large projects to manage additional intermittent renewables and an education campaign to encourage households and business to regularly maintain air conditioning equipment (COA, 2019).

The compliance of Browse with the SGM is discussed in **Section 7.7.2**.

As described in Chapter 2, the controlling provisions under the EPBC Act for the proposed Browse to NWS Project include "the Commonwealth marine area, the protected matter being the environment generally". Under the EPBC Act, the 'environment' includes consideration of:

- ecosystems and their constituent parts including people and communities
- natural and physical resources
- qualities and characteristics of locations, place and areas
- heritage values of places
- social, economic and cultural components of the environment.

These receptors and sensitivities with respect to global GHG emissions are further discussed in **Section 7.5**.

7.3.3 State Legislation and Policy

The Western Australian Government released a GHG Emissions Policy for Major Projects on 28 August 2019. The Policy included an aspirational target of net zero greenhouse gas emissions by 2050. The Minister for Environment will consider how the Policy relates to major proposals assessed under Part IV of the EP Act (Government of Western Australia, 2019).

Public consultation on the WA EPA's draft Environmental Factor Guideline and Technical Guidance relating specifically to GHG emissions closed on 2 September 2019.

Woodside is continuing to work to reduce (net) emissions intensity through improvements in energy efficiency, investments in biosequestration projects and innovation in our production processes. Woodside has a Climate Change Policy described on the website https://www.woodside.com.au/sustainability/climate-change.

7.4 Source Activity

7.4.1 Origin of GHG Emissions

The EIS Guidelines/Environmental Scoping Document for the proposed Browse to NWS Project requires quantification and impact assessment for GHG emissions associated with both the proposed Browse Joint Venture infrastructure and proposed processing of Browse feed gas through North West Shelf Project Extension third party tolling facility infrastructure (EPA 2186, EPBC 2018/8335).

GHG emissions associated with gas extraction and LNG processing activities are typically from two key sources; the combustion of the hydrocarbon-based fuel (Coulson et al., 2010) and pre-existing CO_2 in the hydrocarbon reservoir. Combustion of hydrocarbon-based fuel is used to power export compression and associated processing and utilities. CO_2 content in the hydrocarbon reservoir is a naturally occurring geological phenomenon that must be treated as a waste product during LNG liquefaction. It is not influenced by the design of the processing facilities.

Contemporary large operating and proposed developments off the west coast of Australia include a number of developments where the levels of CO_2 in the reservoir are comparatively high (at an average of *circa* 10 - 20 mol%) compared to historical development on the NWS. The relative proportion of CO_2 emissions associated with reservoir and fuel combustion components are modified accordingly. For example:

- Barossa Development (proposed): *circa* 16–20 mol%
- Gorgon LNG Development (operating): *circa* <1-14 mol%
- Ichthys Project (operating): *circa* 8-17 mol%
- Prelude FLNG: *circa* 9 mol%
- Proposed Browse to NWS Project: *circa* 7-12 mol%.

In terms of the feed gas, the removal of reservoir CO_2 is essentially a purification process, but is also a critical pre-cursor to liquefaction, preventing the formation of solids during that process and the associated plugging of system elements (particularly the heat exchanger) (Li et al., 2011). A variety of methodologies and technologies have been employed to achieve the effective separation and removal of CO_2 from the LNG stream.

In the upstream environment, the separation of reservoir CO_2 from hydrocarbon gas takes place principally within the Acid Gas Removal Unit (AGRU). The CO_2 removed at this point is vented to the atmosphere and this represents one of the principal sources of carbon emissions for the proposed Browse to NWS Project.

Not all the reservoir CO_2 is removed by upstream processing. Further removal may take place in the downstream environment, allowing for installation of a smaller offshore AGRU. This both improves the overall safety profile of the offshore facilities and also results in a slight reduction in overall emissions (due to reduced overall fuel consumption). Under current plans, between 1 mol% and 2.8 mol% CO_2 will be exported via the BTL from the FPSO facilities along with the hydrocarbon gas, with an expected target of 2.5 mol% CO_2. In the downstream environment, a second phase of acid gas removal at KGP will remove the remaining proportion of the reservoir CO_2 and it is expected to be described in the proposed NWSJV's 'North West Shelf Project Extension ERD' (EPA 2186, EPBC 2018/8335). The proportion of reservoir CO_2 that will be emitted at the NWS infrastructure is anticipated to be broadly consistent with the historical reservoir emissions associated with NWS feed gas, subject to the outcome of commercial arrangements. At each AGRU it is possible that hydrocarbons, in particular methane, may be entrained in the reservoir CO_2. Typically, these hydrocarbons are converted to CO_2 by a thermal oxidiser on the vent stream which processes the vent stream of the AGRU. When the thermal oxidiser is not online, the hydrocarbons are vented to atmosphere. These emissions form a small part of the overall CO_2-e vented from the AGRU. Estimates of vented reservoir emissions are inclusive of vented hydrocarbons.

As the separation of reservoir CO_2 from the gas stream occurs prior to liquefaction, the total (i.e. upstream and downstream) reservoir CO_2 emissions are a function of the CO_2 content of the reservoir.

A further source of CO_2 emissions is flaring and fugitive emissions. Flaring refers to the combustion of hydrocarbons that are not able to be processed. The flare is a safety feature to prevent the risk of creating explosive atmosphere in case of a process blowdown. Flaring from the FPSO facilities is expected to be minimal relative to other processing emissions and reservoir emissions. Further information on flaring is provided in **Chapter 3**. Fugitive emissions refer to minor leaks of hydrocarbon gases that occur from the process, or uncombusted hydrocarbons that pass through the flare or gas turbines. Fugitive emissions are expected to be minimal relative to flaring, other processing emissions and reservoir emissions.

Finally, some combustion of fuel and flaring will be associated with downstream processing at KGP. It is noted that the emissions for downstream processing at KGP are expected to be assessed under the NWSJV's 'North West Shelf Project Extension ERD' (EPA 2186, EPBC 2018/8335).

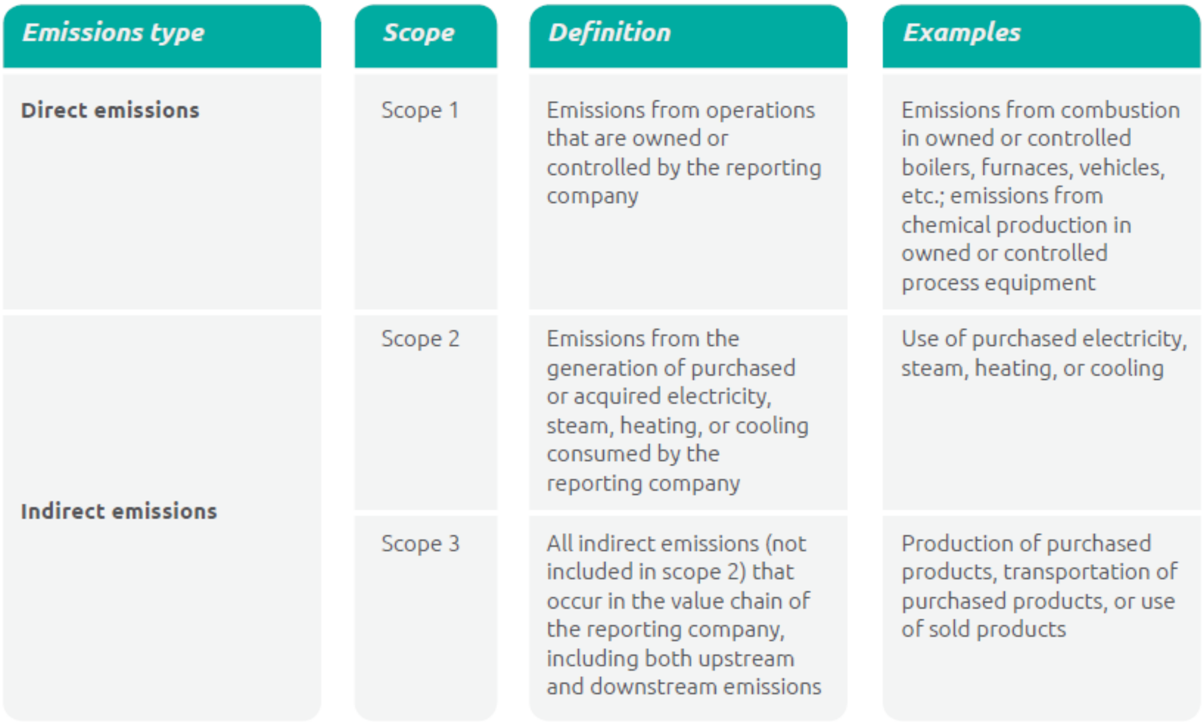
7.4.2 GHG Accounting Principles

GHG emissions are typically characterised by reference to the GHG Protocol Corporate Standard. Originally published in 2001, the GHG Protocol represents a collaboration between the World Resources Institute (WRI) and the World Business Council for Sustainable Development (WBCSD), with the objective of developing an international standard for corporate GHG accounting and reporting. One of the most important outcomes of developing the Protocol has been the widespread recognition of a high-level emissions classification scheme that allows organisations and industries to better define key focus areas for abatement activities. This scheme has been adapted and deployed by national and local regulators and represents a globally accepted subdivision of GHG emissions for evaluation and reporting purposes.

Direct emissions are most commonly associated with the generation of energy, manufacturing processes, transportation and intentional or unintentional GHG ('fugitive') emissions. Indirect emissions are most commonly associated with the consumption of electricity, although numerous other sources exist.

In this context, the GHG Protocol emissions classification scheme is defined in terms of Scope as shown in **Figure 7-1**.

The GHG Protocol is aligned to the definitions for Scope 1 and Scope 2 emissions as defined by the *National Greenhouse and Energy Reporting Regulations 2008 (Cth).*



Emissions type	*Scope*	*Definition*	*Examples*
Direct emissions	Scope 1	Emissions from operations that are owned or controlled by the reporting company	Emissions from combustion in owned or controlled boilers, furnaces, vehicles, etc.; emissions from chemical production in owned or controlled process equipment
Indirect emissions	Scope 2	Emissions from the generation of purchased or acquired electricity, steam, heating, or cooling consumed by the reporting company	Use of purchased electricity, steam, heating, or cooling
	Scope 3	All indirect emissions (not included in scope 2) that occur in the value chain of the reporting company, including both upstream and downstream emissions	Production of purchased products, transportation of purchased products, or use of sold products

Figure 7-1 GHG Protocol Emissions Classification Scheme

7.4.3 Emissions Classification

On the basis of the definitions that support the GHG Protocol's emissions classification scheme, the nature and origin of the main sources of GHG emissions from the proposed Browse to NWS Project are shown in **Table 7-1**.

Table 7-1 Classification of GHG emissions according to the GHG Protocol

Description	Location	Jurisdiction	Emissions Source/Process	Scope
Installation and Construction	Upstream	State	Indirect GHG emissions generated from activities associated with construction, installation and commissioning* of upstream facilities to process Browse gas and operations (by third parties)	Scope 3
	Upstream	Commonwealth	Indirect GHG emissions generated from activities associated with construction, installation and commissioning* of upstream facilities to process Browse gas and operations (by third parties)	Scope 3
Processing and Reservoir CO_2 Emissions	Upstream	State	Direct GHG emissions generated in the State Proposal Area from operational activities associated with upstream processing of Browse gas	Scope 1 (BJV)
	Upstream	Commonwealth	Direct GHG emissions from venting of reservoir CO_2 extracted from the production stream via the FPSOs AGRUs	Scope 1 (BJV)

Description	Location	Jurisdiction	Emissions Source/Process	Scope
	Upstream	Commonwealth	Direct emissions from combustion of hydrocarbon-based fuels required for processing, compression of hydrocarbon gas on the FPSO prior to pipeline export and other operational activities	Scope 1 (BJV)
	KGP	State	Indirect GHG emissions from venting of reservoir CO_2 extracted from the gas exported from the FPSO and vented from the downstream NWSJV AGRU	Scope 1 (NWSJV)
	KGP	State	Indirect emissions from combustion of hydrocarbon-based fuels required for processing of hydrocarbon gas downstream prior to export	Scope 1 (NWSJV)
Third Party Consumption	Transit	Subject to consumer location**	Indirect emissions from transportation of products to the markets into which they will be sold by each Joint Venture Participant, including Domgas	Scope 3
	Market	Subject to consumer location**	Indirect emissions from combustion of products as part of power generation and other energy solutions within final market environment, including Domgas	Scope 3

* *Commissioning emissions in the State Proposal Area are anticipated to be minor, as the FPSO facilities are located in Commonwealth waters.*

** *There are presently no specific contracts for Browse gas. No transport contracts are in place.*

7.4.4 GHG Emissions Estimates

This section provides the carbon emissions estimate for the proposed Browse to NWS Project and describes the approach taken to estimate the forecast GHG emissions for the proposed Browse to NWS Project, based on the GHG Protocol emissions classification scheme. The estimate is based on the current level of concept definition and assumptions regarding commercial arrangements, the feed gas (final composition) and the scale, efficiency, interaction and complexity of the extraction, processing, anticipated production and compression of the product stream.

Forecast GHG emissions incorporate the following sources of GHG emissions:

- Section 7.4.4.1 Installation and Construction
- Section 7.4.4.2 Processing Emissions and Reservoir CO_2 Emissions
    - Processing Emissions Methodology
    - Reservoir CO_2 Methodology
    - Processing and Reservoir CO_2 Emissions Estimate
    - Impact of Browse Gas Export Spec on apportionment of Reservoir CO_2 to the upstream and downstream facilities.
- Section 7.4.4.3 Third Party Consumption Emissions
    - Methodology
    - Estimate.

Key assumptions for all the major sources of GHG emissions relate to:

- The timing and phasing of production well commissioning and start-up across the Calliance, Torosa and Brecknock fields.
- The expected average and maximum production rates from those wells and its decline over life of field.

Emissions from the proposed Browse to NWS Project are expected to be broadly linked to the rate of production. For the first five years following production start-up, currently anticipated to be mid-2020s for the Calliance/Brecknock FPSO, CO_2-e emissions from the proposed Browse to NWS Project lifecycle are expected to increase as production increases. Emissions are expected to stabilise as the FPSOs achieve a steady state until circa 2040.

Once reservoir pressure falls such that the FPSOs no longer achieve a steady state production, emissions progressively reduce in line with production. Some variation in forecast CO_2-e emissions year-on-year is expected for numerous factors, in particular due to commencement of compression, which starts up at different times on different fields and which is subject to a step-wise reduction during production decline.

Emissions Estimate Scenarios

Given the inherent uncertainty of estimating GHG emissions, a range of scenarios have been presented. Explanations for these scenarios are presented below in Table 7-2.

Table 7-2 Description of scenarios presented for GHG emissions estimates

Scenario	Description
Annual Scenarios	
Average year	+ Average (mean) GHG emissions produced over expected field life of 31 years. + Range provided for expected (10.2%) and high (11.6%) reservoir CO_2 composition (weighted average of reservoirs).
Peak production year	+ Peak GHG emissions produced at peak possible production rates (2150mmscfd export), assuming 95% availability. + Range provided for expected (10.2%) and high (11.6%) reservoir CO_2 composition (weighted average of reservoirs).
Total Inventory Scenarios	
Expected field life (31 years)	+ GHG emissions produced over expected field life, achieving expected plateau duration. + Range provided for expected (10.2%) and high (11.6%) reservoir CO_2 composition (weighted average of reservoirs).
Extended Field Life Outcome (44 years)	+ GHG emissions produced over extended field life, achieving extended plateau duration. + Range provided for expected (10.2%) and high (11.6%) reservoir CO_2 composition (weighted average of reservoirs).

7.4.4.1 Installation and Construction

Installation and construction are expected to form a minor component of the overall emissions associated with the proposed Browse to NWS Project. Total installation emissions across the life of the proposed Browse to NWS Project are estimated to be ~1.0 MT CO_2-e (total over field life), with approximately ~0.4MT CO_2-e of the total occurring within State Proposal Area.

7.4.4.2 Processing emissions and reservoir CO_2 emissions

Processing Emissions Methodology

Processing emissions includes the following emissions sources:

- fuel gas consumed
- flaring
- fugitive emissions.

Processing emissions are predominantly generated through the consumption of fuel gas.

An assessment of the quantity of fuel gas required to power the offshore Browse to NWS Project facilities has been completed. This assessment is based on the estimated efficiency of the equipment that has been selected to provide compression power, electricity generation and surplus heat. The power and heat demand of the system has been estimated based on the estimated compression demand, electrical load list demand and heating system demand. The demand for power is expected to be broadly linked to the rate of production and has been forecast based on the expected production in each year. Using the expected composition of the fuel gas, an emissions factor has been developed in accordance with NGERs Method 2.

An assessment on the average flaring rate per day has also been completed, considering both continuous sources (i.e. pilot gas) and episodic flaring associated with planned and unplanned production system events (start-ups and shutdowns). The assessment of episodic flaring considered both the expected frequency of flaring events and the expected quantity flared during the flaring events. An emissions factor for flaring has been taken from NGERs Method 1.

The expected fugitive emissions has been estimated based on the production rate of the facility. An emissions factor has been taken from NGERs Method 1.

In each instance for upstream processing emissions, the estimate of CO_2-e emissions is equal to the quantity of gas consumed, flared or released as fugitives, multiplied by the respective emissions factor. For a summary of emissions factors used in determining upstream processing emissions, refer to Table 7-3.

GHG emissions associated with the proposed Browse to NWS Project in the State Proposal Area will arise from activities in the Torosa field. Due to the position of the FPSOs outside of the State Proposal Area, operational emissions in the State jurisdiction will be limited to IMR activities on subsea infrastructure and contingent drilling and completions activities on installed wells.

Downstream processing GHG emissions have been apportioned based on the proportion of NWS processing plant capacity that Browse gas utilises, relative to the greenhouse gas footprint currently approved for the facility as per Ministerial Statement 536. These are expected to be further described in the NWSJV's 'North West Shelf Project Extension ERD' (EPA 2186, EPBC 2018/8335).

Table 7-3 Emissions Factors used for Browse to NWS Project Processing Emissions

Source/fuel	Energy Content	kg CO_2-e/ GJ (CO_2)	kg CO_2-e/ GJ (CH_4)	kg CO_2-e/ GJ (N_2O)	kg CO_2-e/ kg Product	NGERs Reference
Fuel Gas Upstream (Scope 1 BJV)	40.0 x 10^{-3} (GJ/m^3)	52.7	0.11	0.03	2.88 (per kg fuel gas)	S2.21-2 Method 2
Flaring Upstream	N/A	2.7 (per kg flared)	0.1 (per kg flared)	0.03 (per kg flared)	2.83 (per kg flare)	S3.67 Method 1
Fugitives Total	1.2kg CO_2-e (CH_4) Total (per tonne LNG produced) + 1.4kg CO_2-e (CH_4) Total (per tonne condensate produced)					S3.72 Method 1
Processing Emissions Downstream (Scope 1 NWSJV)	Please refer NWS JV's proposed 'North West Shelf Project Extension ERD' (EPA 2186, EPBC 2018/8335)					

Please note, as the emissions factor for fuel gas upstream has been developed based on the composition of the proposed Browse to NWS Project fuel gas (in accordance with NGERs Method 2), the emissions factor varies slightly from other similar upstream gas projects. The emissions factor used for flaring is the same for all projects described below in Table 7-4, as it takes the emissions factor described in NGERs Method 1 (S3.67).

Table 7-4 Comparison of Emissions Factors used for Fuel Gas across comparable upstream facilities

Project – Fuel Gas	Energy Content (GJ/m^3)	kg CO_2-e/ GJ (CO_2)	kg CO_2-e/ GJ (CH_4)	kg CO_2-e/ GJ (N_2O)	kg CO_2-e/ GJ (Total)
Browse to NWS Project	40.0 x 10^{-3}	52.7	0.11	0.03	52.84
Barossa	39.3 x 10^{-3}	51.4	0.1	0.03	51.53
Icthys	Emissions factor not provided in draft EIS/ERD. Methodology used was consistent with the National Greenhouse Account Factors.				
APLNG	37.7 x 10^{-3}	51.1	0.2	0.03	51.33

* *Note all emissions data for Australian facilities has been sourced from regulatory authorisations (i.e. environmental impact statements, environmental review documents and management plans)*

Reservoir CO_2 Emissions Methodology

An assessment of the total quantity of reservoir CO_2 emitted has been completed. The assessment assumed that all reservoir CO_2 must be removed prior to liquefaction of the gas, either at the upstream or downstream facility. The estimate of reservoir CO_2 was based on the expected CO_2 composition of the reservoirs. Due to uncertainty of composition in the reservoir, a high reservoir CO_2 composition case has also been provided.

The amount emitted at each location will be dependent on the proportion of reservoir CO_2 exported from the BJV FPSO to the NWS facilities, i.e. the Browse export gas specification. There is some inherent uncertainty in the Browse export gas specification, which is further addressed below. Upstream and downstream reservoir emissions have been estimated **Table 7-5**, based on a gas export specification target of 2.5mol% CO_2.

Processing and Reservoir CO_2 Emissions Estimate

A summary inventory of the estimated GHG emissions is provided in **Table 7-5**. For the proposed Browse to NWS Project, SGM baseline requirements are expected to be achieved through use of offsets (described in **Section 7.7.2**). To account for the impact of SGM baseline requirements, estimates for both gross forecast emissions and net forecast emissions have been provided. These terms have the following definitions:

- **Gross Forecast Emissions**: All greenhouse gas emissions from the final design of the proposed Browse to NWS Project facilities (upstream and downstream), after energy efficiency and emissions reductions design measures (described in **Section 7.7.1**) have been incorporated.
- **Net Forecast Emissions**: The Gross Forecast Emissions minus those offset by carbon credits (described in **Section 7.7.2**).

Forecast Scope 1 (BJV and NWS JV) GHG emissions using the emissions factors are shown in **Table 7-5** below.

While CO_2 accounts for the majority of GHG emissions associated with the proposed Browse to NWS Project, other related emissions will also occur across the full scope of proposed project activities, including methane and nitrous oxide. All estimates for CO_2-e include both methane and nitrous oxide. The Global Warming Potential (GWP) adopted to determine the amount of CO_2-e contributed from both methane and nitrous oxide aligns to the *National Greenhouse and Energy Reporting Regulations 2008*, which at time of writing reflected the IPCC's Fourth Assessment Report. A breakdown of the relative contribution of these emissions on a gas-by-gas basis to forecast FPSO GHG emissions by CO_2-e equivalent is presented in **Table 7-6**.

Note that hydrochlorofluorocarbons/chlorofluorocarbons (HFCs/CFCs) will not be used as refrigerants on the FPSO facilities.

GHG emissions have been estimated based on NGERs emissions factors for Australia.

Table 7-5 Forecast Scope 1 (BJV and NWS JV) GHG emissions summary

CO_2-e MT	Average year	Peak production year	Total expected field life	Total extended field life
Upstream (BJV Scope 1)				
Reservoir Emissions[1]	2.3 (2.6)[2]	4.0 (4.6)	70 (81)	93 (107)
Fuel Gas	1.3	2.1	40	53
Flaring	0.07	0.07	2	3
Fugitives	0.01	0.02	0.3	0.4
Upstream Total	**3.6 (4.0)**	**6.2 (6.8)**	**112 (123)**	**149 (163)**
Downstream (Apportioned NWSJV Scope 1)				
Reservoir Emissions[1]	0.5	0.9	16	24
Processing Emissions (fuel and flare)	2.3	4.3	72	98
Downstream Total	**2.8**	**5.2**	**88**	**122**
Installation				
Installation	Not Estimated		1.0	1.0
SGM Carbon Credit Requirements				
SGM Carbon Credit Requirements	1.61	1.61	50	N/A[3]
Totals				

CO_2-e MT	Average year	Peak production year	Total expected field life	Total extended field life
Sub-total (reservoir)	**2.8 (3.2)**	**4.9 (5.5)**	**87 (98)**	**117 (131)**
Gross Total (Upstream + Downstream)	**6.4 (6.8)**	**11.4 (12.0)**	**200 (211)**	**272 (285)**
Net Total (Upstream + Downstream – Carbon Credits)	**4.8 (5.2)**	**9.8 (10.4)**	**150 (161)**	**N/A[3]**

[1] *Upstream and downstream reservoir emissions have been estimated based on the maximum expected case given a gas export specification target of 2.5mol% CO_2. The sub-total (reservoir) reflects the total upstream plus downstream emissions, regardless of export CO_2 specification. Estimates of emission implications for a 1 mol% to 2.8 mol% CO_2 gas export specification are presented in Table 7-7. Note the gas export specification is dependent on the outcome of final commercial arrangements.*

[2] *Bracketed emissions refer to high reservoir CO_2 composition scenario. Note that downstream reservoir emissions are impacted by the gas export specification and so, in the high reservoir CO_2 scenario, the additional reservoir CO_2 is vented upstream.*

[3] *Based on current SGM requirements, it is anticipated that reservoir CO_2 emissions will contribute to the proposed Browse to NWS Project exceeding facility baseline by approximately 50Mt CO_2-e, which would need to be offset in accordance with the rules of the SGM. This estimate is based on a mid-case reservoir outcome and is subject to change should a different reservoir outcome be realised or if the rules and assumptions which underpin the SGM baseline also change (including the production variables, default and leading practice emission intensities required to define any potential alternative, which are yet to be published in the Schedules associated with the National Greenhouse and Energy Reporting (Safeguard Mechanism) Rule 2015).*

[4] *As it is a regulatory requirement to determine the baseline on the mid-case forecast emissions, no estimate of baseline or carbon credit requirements has been made for an extended field life scenario.*

A gas-by-gas breakdown of gross forecast BJV Scope 1 greenhouse gas emissions has been provided in Table 7-6. Please note that the gas-by-gas breakdown on an annual basis will depend on the availability of the thermal oxidiser on the AGRU vent stream.

Table 7-6 Gross Forecast GHG emissions summary – gas by gas (BJV Scope 1)

CO_2-e MT	Average year	Total expected field life	Proportion of CO_2-e
Total CO_2	3.6 (4.0)	112 (123)	99.0%
Total CH_4	0.03	1.12	1.0%
Total N_2O	<0.01	0.03	0.03%

Browse Gas Export Specification - Apportionment of Reservoir CO_2 (Upstream-Downstream)

While an estimate for reservoir emissions based on expected reservoir outcomes is provided in Table 7-5, the individual BJV (Scope 1) and NWSJV (Scope 1) reservoir related emissions are indicative, as the amount emitted at each location is dependent on the proportion of reservoir CO_2 exported from the BJV FPSO to the NWS facilities, i.e. the Browse export gas specification. It is anticipated that the Browse export gas specification will allow a CO_2 composition range of between 1 mol% and 2.8 mol%. However, this is dependent on the outcome of final commercial arrangements between the Browse JV and NWS JV.

To account for this range in potential outcomes, which impacts the relative quantity of reservoir emissions released at each location (but not the total quantity), the reservoir emissions estimated to occur in each jurisdiction under the range of expected export gas specification outcomes has been provided in Table 7-7. This is dependent on the outcome of final commercial arrangements between the Browse JV and NWS JV.

Table 7-7 Forecast individual reservoir related emissions, dependant on the Browse export gas specification

Export Specification Scenario	CO_2-e MT	Average year	Peak production year	Total expected field life	Total extended field life
High CO_2 FPSO Export Specification (Less at FPSO, more at NWS)	Upstream BJV Scope 1	2.2 (2.6)[1]	3.9 (4.5)	68 (79)	91 (105)
	Downstream Apportioned NWSJV Scope 1	0.6	1.1	19	27
	Total (reservoir)	**2.8 (3.2)**	**4.9 (5.5)**	**87 (98)**	**117 (131)**
Low CO_2 FPSO Export Spec (More at FPSO, less at NWS)	Upstream BJV Scope 1	2.6 (2.9)	4.5 (5.1)	80 (91)	108 (122)
	Downstream Apportioned NWSJV Scope 1	0.2	0.4	7	10
	Total (reservoir)	**2.8 (3.2)**	**4.9 (5.5)**	**87 (98)**	**117 (131)**

[1] *Bracketed emissions refer to high reservoir CO_2 composition scenario. Note that downstream reservoir emissions are impacted by the gas export specification, and so, in the high reservoir CO_2 scenario, the additional reservoir CO_2 is vented upstream.*

7.4.4.3 Third party consumption

Methodology

An estimate of the quantity of greenhouse gas emissions arising from third party consumption has been completed.

For the consumption of LNG anticipated to be produced from the proposed Browse to NWS Project, which is expected to predominately occur internationally, an emissions factor has been sourced from the Ecoinvent v3.5 database. This emissions factor considers the transport, regasification, distribution and final combustion of LNG.

For the consumption of Domgas anticipated to be produced from the proposed Browse to NWS Project, which is expected to predominately occur domestically, an emissions factor has been developed based on NGERs. This emissions factor considers the distribution and final combustion of natural gas. Fugitive emissions of the gas during transmission (i.e. along BTL pipeline and subsequently the Bunbury to Dampier Pipeline) have been estimated in accordance with *NGERs Measurement Determination* S3.76 and are not significant. Therefore, they are not presented further.

NGERs end point combustion factors have been used for third party consumption of LPG and condensate, as these constitute a minority of the total products anticipated to be produced from the proposed Browse to NWS Project. The transportation and distribution emissions associated with these products are considered to be negligible when compared to the total Scope 3 emissions estimate.

In each instance for Scope 3 Emissions, the estimate of CO_2-e emissions is equal to the based on the quantity of product consumed, multiplied by the respective emissions factor.

Table 7-8 contains the emissions factors used to inform GHG estimates.

Table 7-8 Emissions Factors used for Browse to NWS Project Transit and Market Emissions

Source/fuel	Energy Content	kg CO_2-e/ GJ (CO_2)	kg CO_2-e/ GJ (CH_4)	kg CO_2-e/ GJ (N_2O)	kg CO_2-e/ GJ (unless otherwise stated)	NGERs Determination Reference
Third Party – LNG	N/A	N/A	N/A	N/A	3.13 (per kg product)	Ecoinvent 3.5
Third Party – Domgas	N/A	N/A	N/A	N/A	2.93 (per kg product)	Schedule 1 (Consumption) S3.80 (Distribution)
Third Party – LPG	25.7 (GJ/kL)	60.2	0.2	0.2	60.6	Schedule 1
Third Party – Condensate	46.5 (GJ/t)	61	0.1	0.2	61.3	Schedule 1

The methodology used by Ecoinvent v3.5 follows the international standards for lifecycle assessment. The Ecoinvent v3.5 emissions factor is based on individual production processes which contain Scope 1 emission factors, covering all greenhouse gas emissions, as connected along a production chain to deliver intermediate or final production processes. The methodology includes infrastructure, manufacturing processes, fugitive emissions as well as all energy-related emissions. Allocation between coproducts is done based on physical parameters, where available, such as energy content for coproduced energy products and, where a physical basis cannot be established, allocation is based on relative economic value of coproducts.

Ecoinvent v3.5 represents arguably the largest public collection of inventory data in the world, covering over 5000 products and containing 17000 unit processes. It has been recognised as emission factor source for the European Union Renewable Energy Direction greenhouse gas methodology and sits in the background of many of the National Carbon Offset Scheme (NCOS) emission factors. The Ecoinvent factors are therefore aligned in methodology to the principles of the NGERs methodology.

Estimate

Third party consumption emissions, as per the emissions factors used in **Table 7-8**, reflect emissions associated with the final combustion and use of the product and are shown in **Table 7-9**. Third party consumption emissions form the largest part of the overall emissions related to the Browse to NWS Project. It is expected that the majority of these GHG emissions will occur internationally and be managed and mitigated through local and international emissions control frameworks.

Table 7-9 Forecast Third Party consumption GHG emissions summary

CO_2-e MT	Average year	Peak production year	Total expected field life	Total extended field life
Third Party Consumption (Scope 3)				
Consumption – LNG (transport, regasification and distribution, and combustion)	22	38	691	944
Consumption – Domgas (distribution and combustion)	3.3	5.6	103	134
Consumption – LPG (Combustion only)	0.9	1.5	28	12
Consumption – Condensate (Combustion only)	5.6	10.6	173	241
Total	**32**	**55**	**995**	**1330**

The sum of all average year Scope 1 (BJV and NWS JV) (**Table 7-5**, total average year) and Scope 3 (**Table 7-9**, total average year) emissions is 36.8 MT.

7.4.5 Emissions Lifecycle and Intensity

7.4.5.1 Estimate lifecycle emissions and emissions intensity

Assessing the potential climate change impact of a proposed project requires an understanding of both direct and indirect GHGs. A lifecycle approach is useful to both collate this information into a single value and to compare impact between different products or value chains.

When conducting a lifecycle assessment, boundaries between upstream and downstream value chain components must be set. For example, **Figure 7-2** represents the anticipated emissions intensity of proposed processing Browse feedgas at the KGP and delivering product to China for use in a combined cycle gas turbine. This shows that electricity sourced from Browse gas has a lifecycle emissions intensity of 550 $kgCO_2$-e/MWh.

The IPCC summarised the lifecycle emissions intensity of electricity from various emissions sources (IPCC, 2011). This showed that the median emissions intensity of gas fuelled electricity was circa 450$kgCO_2$-e/MWh and that the Browse emissions intensity fits within the interquartile range for global gas fired electricity of 400-550kg CO_2-e/MWh. IPCC also showed that oil and coal power electricity generates 1000kg CO_2-e/MWh, whilst renewables and nuclear generate 0-50kg CO_2e/MWh.

Based on the comparison between electricity generated from Browse LNG and the electricity generated from coal, 121 $kgCO_2$e/kWh is emitted in Australia (22% of 550) and 450 $kgCO_2$e/kWh is saved in the global energy system. In this case, every tonne of GHG emitted in Australia could displace 3.7 tonnes of GHG elsewhere in the global energy system.

7.4.5.2 Natural gas in the context of global emissions

The scientific consensus on climate change, and the commitment of global governments to reduce emissions, is clear. There is also a need to both improve local air quality and increase access to modern energy sources. Access to clean, affordable and reliable energy improves living standards dramatically and the world's growing population is driving increased energy demand.

Numerous independent energy and climate bodies agree that natural gas has a significant role to play in achieving both a reduction in net global emissions and an increased access to a reliable modern energy supply that supports a progressive transition to renewable energy sources. The IPPC's 2014 Synthesis Report said that "GHG emissions from energy supply can be reduced significantly" by switching to gas. According to the IPCC, electricity generated from gas has on average half the GHG emissions of electricity generated from coal (IPCC, 2014). According to the International Energy Agency (IEA), in 2018 coal-to-gas switching helped avert 95 MT of CO_2 emissions (IEA, 2019).

A key technical challenge with the widespread deployment of renewables is the low capacity factor, as renewable power such as from wind and solar can be intermittent or inconsistent. As a readily dispatchable and reliable power source, gas-fired power is an ideal partner with renewables, as it can be quickly turned on to provide system stability when renewable power generation or electricity demand fluctuates. By providing this firming capacity, gas-fired power allows high renewable penetration in the form of a reliable power source to help resolve intermittency issues.

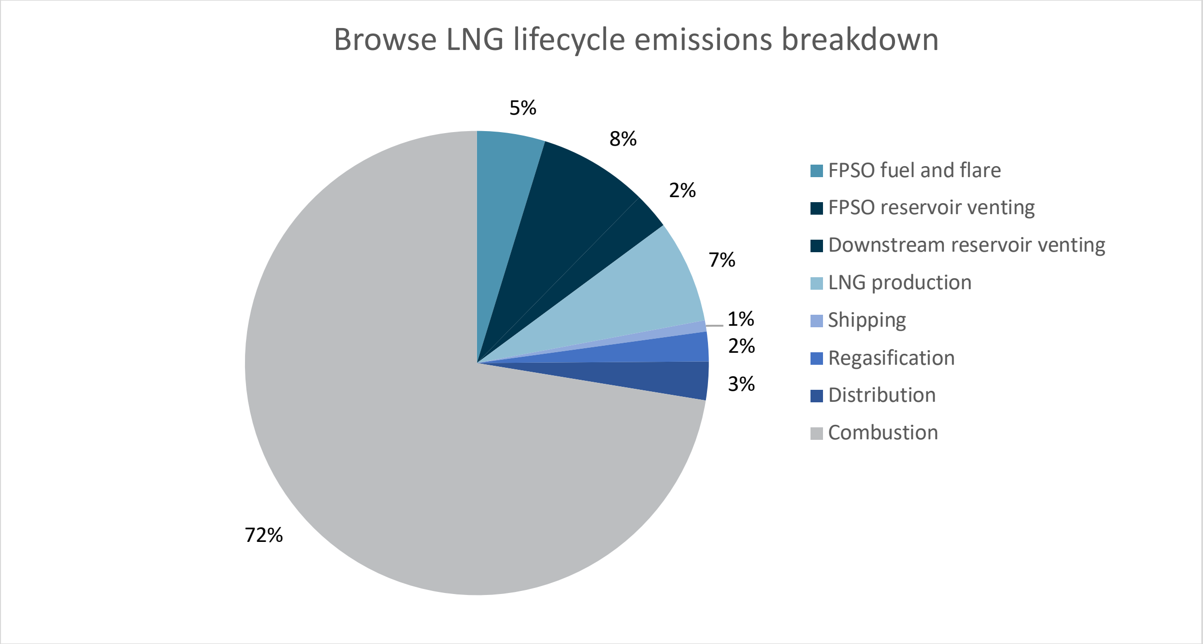


Figure 7-2 Proposed Browse to NWS Project lifecycle emissions intensity

Each year the IEA publishes a World Energy Outlook (WEO). Since 2017, the WEO has included a Sustainable Development Scenario (SDS), which describes an energy system that satisfies the three objectives of mitigating climate change, providing universal energy access by 2030 and reducing the severe health impacts of air pollution. Emissions projections in the SDS are "lower than most published decarbonisation scenarios based on limiting long-term global average temperature rise to 1.7-1.8°C" (IEA, 2019).

The SDS shows that natural gas continues to increase until at least 2040, the end of the period modelled (**Figure 7-3**). In the consumer countries relevant to the proposed Browse to NWS Project, gas consumption grows by 130% between 2017 and 2040. This suggests that increased gas use is not only consistent with the SDS but necessary if the goals of climate change mitigation, air quality improvements and energy access are to be achieved.

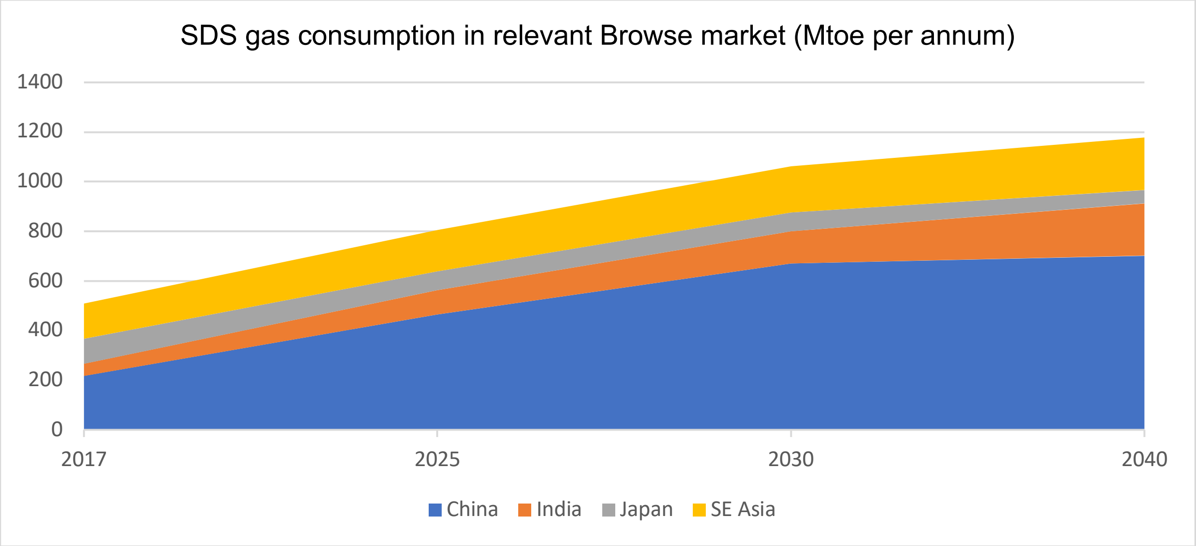

Figure 7-3 Forecast gas consumption in the IEA's SDS in relevant Browse markets (Mtoe)

7.5 Receptors and Receptor Sensitivity to Global GHG emissions

A recent Intergovernmental Panel on Climate Change (IPCC) Report (Hoegh-Guldberg et al., 2018) summarised the potential impact of human-induced climate change (at 1.5 and 2°C) on a range of climatic variables (e.g. temperature, precipitation, drought, extreme events) and the likely consequence to different ecosystems and ecosystem services, at a range of spatial scales.

Modelling indicated that temperatures will increase across Australia, rainfall patterns will change significantly and extreme events such as droughts, floods and wildfires will become more common. These changes are likely to impact on individual species, ecosystems and ecosystem services such as food and water availability. Within decades, environments across Australia may be substantially different. Biodiversity will be affected by climate change in a variety of ways and there will be much spatial variation in ecological change (CSIRO, 2015).

A report by Australia's Biodiversity and Climate Change Advisory Group (Steffen et al., 2009) in 2009 gives a summary of potential impacts to marine and terrestrial species, habitats and ecosystems across Australia. The impacts to taxa are outlined in **Table 7-10** and the impacts to ecosystems in **Table 7-11**.

7.5.1 Species-related Impacts from Global GHG Emissions

Extensive modelling and monitoring studies over the last twenty years provide considerable evidence that global climate change is already affecting and will continue to affect species (Hoegh-Guldberg et al., 2018). In addition, climate-change related impacts to flora and fauna are likely to be highly species-dependent and spatially variable. However, fauna distribution patterns are likely to shift in response to a changing climatic regime. Species distributions are likely to shift towards the poles and upwards in elevation and shifts in phenology (earlier spring and later autumn life history events) are the most frequently observed and cited ecological responses to climate change (Dunlop et al., 2012).

Climate change may not only change species distribution patterns but also life-history traits such as migration patterns, reproductive seasonality and sex-ratios (see **Table 7-10**). For example, Dunlop (2009) highlighted that in Australia, migratory birds have undergone changes in the first arrival date (3.5 days/decade), and last date of departure (5.1 days/decade) (Beaumont et al., 2006). Pairing of sleepy lizards has been observed to start earlier and last longer when the last months of winter are warmer (Bull and Burzacott, 2002). Climate change may account for earlier arrival of bird species in the Australian Alps, but the change appears not to be a simple consequence of incremental annual warming resulting from earlier snow-melt (Green, 2006; Norment and Green, 2004)

Table 7-10 Overview of impacts of climate change to the future vulnerability of particular taxa (modified after Steffen et al 2009)

Taxa	Potential vulnerability
Mammals	Narrow-ranged endemics susceptible to rapid climate change in situ (Williams et al., 2003); changes in competition between grazing macropods in tropical savannas mediated by changes in fire regimes and water availability (Ritchie and Bolitho, 2008); herbivores affected by decreasing nutritional quality of foliage as a result of CO_2 fertilisation.
Birds	Changes in phenology of migration and egg-laying; increased competition of resident species; breeding of waterbirds susceptible to reduction; top predators vulnerable to changes in food supply; rising sea levels affecting birds that nest on sandy and muddy shores, saltmarshes, intertidal zones, coastal wetlands and low-lying islands; saltwater intrusion into freshwater wetlands affecting breeding habitat.
Reptiles	Warming temperatures may alter sex ratios of species with environmental sex determination to cope with warming in situ.
Amphibians	Frogs may be the most at-risk terrestrial taxa. Amphibians may experience altered interactions between; pathogens, predators and fires.
Fish	Freshwater species vulnerable to reduction in water flows and water quality; limited capacity for freshwater species to migrate to new waterways; all species susceptible to flow-on effects of warming on the phytoplankton base of food webs.
Invertebrates	Expected to be more responsive than vertebrates due to short generation times, high reproduction rates and sensitivity to climatic variables.
Plants	Climate change may impact various functional dynamics of plants due to changes in; increasing CO_2, fires, plant phenology and specific environmental characteristics.

7.5.2 Projected Climate Change Impacts to Ecosystems from Global GHG Emissions

The results of climate change, such as altering temperature, rainfall patterns and fire regimes, are likely to lead to changes in vegetation structure across all terrestrial ecosystems within Australia (**Table 7-11**; Dunlop et al., 2012). Increases in fire regimes will impact Australian ecosystems by altering composition structure, habitat heterogeneity and ecosystem processes. Changes in climate variability, as well as averages, could also be important drivers of altered species interactions, both native and invasive species (Dunlop et al., 2012). Climate change could result in significant ecosystem shifts, as well as alterations to species ranges and abundances within those ecosystems (Hoegh-Guldberg et al., 2018).

Table 7-11 Projected impacts of CO_2 rise and climate change on Australian ecosystems (modified after Steffen et al 2009)

Key component of environmental change	Projected impacts on ecosystems
Coral reefs	
CO_2 increases leading to increased ocean acidity	Reduction in ability of calcifying organisms, such as corals, to build and maintain skeletons.
Sea surface temperature increases, leading to coral bleaching	If frequency of bleaching events exceeds recovery time, reefs will be maintained in an early successional state or be replaced by communities dominated by macroalgae.
Oceanic systems (including planktonic systems, fisheries, sea mounts and offshore islands)	
Ocean warming	Many marine organisms are highly sensitive to small changes in average temperature (1–2 degrees), leading to effects on growth rates, survival, dispersal, reproduction and susceptibility to disease.

Key component of environmental change	Projected impacts on ecosystems
Changed circulation patterns, including increase in temperature stratification and decrease in mixing depth, and strengthening of East Australian Current	Distribution and productivity of marine ecosystems is heavily influenced by the timing and location of ocean currents; currents transfer the reproductive phase of many organisms. Climate change may suppress upwelling in some areas and increase it in others, leading to shifts in location and extent of productivity zones.
Changes in ocean chemistry	Increasing CO_2 in the atmosphere is leading to increased ocean acidity and a concomitant decrease in the availability of carbonate ions.
Estuaries and coastal fringe (including benthic, mangrove, saltmarsh, rocky shore, and seagrass communities)	
Sea level rise	Landward movement of some species as inundation provides suitable habitat, changes to upstream freshwater habitats will have flow-on effects to species.
Increase in water temperature	Impacts on phytoplankton production will affect secondary production in benthic communities.
Savannas and grasslands	
Elevated CO_2	Shifts in competitive relationships between woody and grass species due to differential responses.
Increased rainfall in north and northwest region	Increased plant growth will lead to higher fuel loads, in turn leading to fires that are more intense, frequent and occur over large areas.
Tropical rainforests	
Warming and changes in rainfall patterns	Increased probability of fires penetrating into rainforest vegetation resulting in shift from fire-sensitive vegetation to communities dominated by fire-tolerant species.
Change in length of dry season	Altered patterns of flowering, fruiting and leaf flush will affect resources for animals.
Rising atmospheric CO_2	Differential response of different growth forms to enhanced CO_2 may alter structure of vegetation.
Temperate forests	
Potential increases in frequency and intensity of fires	Changes in structure and species composition of communities with obligate seeders may be disadvantaged compared with vegetative resprouters.
Warming and changes in rainfall patterns	Potential increases in productivity in areas where rainfall is not limiting; reduced forest cover associated with soil drying projected for some Australian forests.
Inland waterways and wetlands	
Reductions in precipitation, increased frequency and intensity of drought	Reduced river flows and changes in seasonality of flows.
Changes in water quality, including changes in nutrient flows, sediment, oxygen and CO_2 concentration	May affect eutrophication levels, incidence of blue-green algal outbreaks.
Sea level rise	Saltwater intrusion into low-lying floodplains, freshwater swamps and groundwater; replacement of existing riparian vegetation by mangroves.
Arid and semi-arid regions	
Increasing CO_2 coupled with drying in some regions	Interaction between CO_2 and water supply critical, as 90% of the variance in primary production can be accounted for by annual precipitation.
Shifts in seasonality or intensity of rainfall events	Any enhanced runoff redistribution will intensify vegetation patterning and erosion cell mosaic structure in degraded areas. Changes in rainfall variability and amount will also impacts on fire frequency. Dryland salinity could be affected by changes in the timing and intensity of rainfall.

Key component of environmental change	Projected impacts on ecosystems
Warming and drying, leading to increased frequency and intensity of fires	Reduction in patches of fire-sensitive mulga in spinifex grasslands potentially leading to landscape-wide dominance of spinifex.
Alpine/montane areas	
Reduction in snow cover depth and duration	Potential loss of species dependent on adequate snow cover for hibernation and protection from predators; increased establishment of plant species at higher elevations as snow pack is reduced.

7.5.2.1 Terrestrial Ecosystems

All terrestrial ecosystems are likely to be impacted by a changing climate (Table 7-11; Steffen et al 2009; Hughes 2010; Dunlop et al. 2012; Hoegh-Guldberg et. al. 2018). The predicted impact of climate change on these ecosystems is highly variable, both between ecosystems and within individual ecosystems ((Dunlop et al., 2012). Below is a summary of impacts to key terrestrial ecosystems (other ecosystems are summarised in Table 7-11).

Tropical Rainforests

Projections of future climate changes in the wet tropics of Australia under different scenarios are outlined by Mcinnes (2015). It is likely that temperatures in the wet tropics will become hotter and potentially fires and cyclones will be more intense. Consequently, there is an increased probability of fires penetrating into rainforest vegetation resulting in a shift from fire-sensitive vegetation to communities dominated by fire-tolerant species; and changing rainforest disturbance regime as cyclones become more intense) (Hughes, 2011; Steffen et al., 2009). Changes in the timing of seasons (e.g. extended summer) could cause change in the seasonal response of plants, and alterations to species ranges and abundances (Hoegh-Guldberg et al., 2018).

Alpine/ Montane Areas

Alpine systems are generally considered to be among the most vulnerable to future climate change (Hughes 2003). The extent of true alpine habitat in Australia is very small (0.15% of the Australian land surface) with limited high-altitude refuge (Hughes, 2003).

Australian alpine regions are home to a variety of alpine vertebrates who rely on snow cover for their survival. There is evidence of a reduction in populations of dusky antechinus, broad-toothed rats and the mountain pygmy possum. The first two species are active under the snow throughout winter and are therefore subject to increased predation by foxes when snow is reduced (Hughes, 2003). The pygmy possum depends upon snow cover for stable, low temperatures during hibernation (Hughes, 2003).

7.5.2.2 Marine Ecosystems

Sea surface temperatures have increased across the globe over recent decades which poses a significant threat to marine ecosystems including changes to species abundance, community structure and increased frequency and intensity of thermally induced coral bleaching events (CSIRO, 2017).

Between 1920 and 2000, sea level is estimated to have risen on average 1.2 mm per year due to climate change (Church et al., 2006). In addition to changes in sea level, oceanic warming has also served to alter ocean currents around Australia. In response to both ocean warming and stratospheric ozone depletion the East Australian Current has increased in strength by about twenty percent since 1978 (Cai and Cowan, 2006).

Sea-surface temperatures are projected to continue to increase, with estimates of warming in the Southern Tasman Sea of between 0.6 and 0.9°C and between 0.3 and 0.6°C elsewhere along the Australian coast by 2030 (Church et al., 2006). Sea levels are predicted to increase by 18 to 59 cm by 2100 in response to both thermal expansion and melting of ice-sheets (Solomon et al., 2007). This would lead to some coastal inundation affecting mangroves, salt marshes and coastal freshwater wetlands. Furthermore, as CO_2 is gradually absorbed by oceans and fresh water, the water becomes more acidic, which increases the solubility of calcium carbonate, the principal component of the skeletal material in aquatic organisms (Steffen et al., 2009). Below is a summary of potential climate change impacts to two key ecosystems - mangroves and coral reefs.

Mangroves

Mangrove ecosystems in Australia could face higher temperatures, increased evaporation rates and warmer oceans (McInnes, 2015) as well as an associated sea-level rise (Hoegh-Guldberg et al., 2018). Modelling indicates an increased likelihood of future severe and extended droughts across parts of Northern Australia (Dai, 2013). Consequently, mangrove ecosystems may increase their southern range as a result of warmer temperatures. However, higher temperatures and evaporation rates, and extended droughts could lead to die-offs in northern Australia and a change in mangrove distribution and abundance (Duke et al., 2017). Mangrove systems should cope with rising sea-level by accumulating more peat or mud, giving them the opportunity to adjust to a rising sea level (Field, 1995).

Coral Reefs

Climate change has emerged as a threat to coral reefs, with temperatures of just 1°C above the long-term summer maximum for an area over 4–6 weeks being enough to cause mass coral bleaching and mortality (Baker et al., 2008; Hoegh-Guldberg, 1999; Hughes et al., 2017; Spalding and Brown, 2015). Coral mortality or die off following coral bleaching events can stretch across thousands of square kilometres of ocean (Gilmour et al., 2016; Hoegh-Guldberg, 1999; Hughes et al., 2017). The impacts associated with a warming ocean, coupled with increasing acidification, are expected to undermine the ability of tropical coral reefs to provide habitat for fish and invertebrates, which together provide a range of ecosystem services (e.g., food, livelihoods, coastal protection); (Hoegh-Guldberg et al., 2018).

As described in Chapter 5, evidence of thermal-induced bleaching and the associated impacts has been observed during long term monitoring of the corals at Scott Reef which lie within the proposed Browse Development Area. These corals have experienced four thermally induced bleaching events since 1998. While Scott Reef showed rapid recovery of corals after bleaching events, the increasing frequency of these events due to climate change has the potential to affect this recovery (Gilmour et al., 2016).

7.5.3 Projected Climate Change Impacts to Social, Economic and Cultural Aspects from Global GHG Emissions

Noting the inherent uncertainty in estimating the impacts of climate change, Table 7-12 below provides a summary of possible impacts of climate change on social and economic components from global GHG emissions. The data is drawn from existing Australian Government resources (Climate Change Authority, 2014; DoEE 2019).

Table 7-12 Possible impacts of CO_2 rise and climate change on Australian social, economic and cultural aspects

Social/economic categories & impact causes	Possible impacts
Cities and the built environment	
Sea level rise, flooding, ocean acidification, wildfire and other extreme events	Both gradual changes (sea-level and temperature rise, ocean acidification) and extreme events (flash floods, heatwaves and bushfires) may increase repair frequency and drive relocation.
Agriculture, forestry, fisheries, broader industries and employees	
Decrease in rain fall	Reduced agricultural yields in Southern Australia.
Change in temperature	Livestock under greater heat stress resulting in reduced productivity and reproductive rates.
Change in climate	Changes in growing season and location may impact food transport costs and availability
	Increased severity and frequency of extreme weather events, water shortages and exposure to tropical diseases may impact industry and labor mobility. Tourism and agricultural industries may be the most vulnerable.
Water resources	
Changes in groundwater	Altered groundwater recharge rates and supplies, seawater intrusion to coastal aquifers, reduction of freshwater availability on small islands, and increased demand from communities and industries.

Social/economic categories & impact causes	Possible impacts
Change in temperature	Potential increase in the risk of bacterial contamination in water supplies, blue-green algal outbreaks and acid-sulphate soil issues.
Health and wellbeing, human factors	
Changes to ecosystem services	Impaired services such as clean air, fresh water, and protection from natural disasters.
Increase in temperature and rainfall patterns	Increased risk of temperature related injury, disease and death. This includes an increased area of land suitable for mosquitoes that transmit disease.
Increase in extreme events	Increased risk of injuries, disease, and disruption to health services.
Change in climate	Drought has been linked to decreased mental health, particularly in rural communities.
	Aboriginal Australians may experience a higher impact from climate change due to close connections to the natural environment (both cultural and income related) and higher rates of socio-economic disadvantage.

7.5.4 Projected Effect of Global Emissions on Receptor Trends

The IPCC Special Report describes the impacts of warming above pre-industrial levels to key receptor groups including terrestrial ecosystems, mangroves, warm-water corals, unique and threatened systems, and arctic regions (Hoegh-Guldberg et. al. 2018). These receptor groups show varying sensitivity to warming conditions, with a range of responses shown at 1°C warming; from corals suffering moderate impacts, to mangroves not showing any impacts that are detectable and attributable to climate change (Hoegh-Guldberg et al., 2018). Once warming reaches 1.5°C, all receptor groups show impacts attributable to climate change, with severity ranging from moderate impacts that are detectable and attributable to climate change (mangroves), to impacts that are severe and widespread (warm-water corals) (Hoegh-Guldberg et al., 2018). At the point where global temperature rise due to climate change reaches 2°C, increasing numbers of receptor groups suffer impacts which are high to very high, and likely to be irreversible (terrestrial ecosystems, warm-water corals, unique and threatened systems, and arctic regions) (Hoegh-Guldberg et al., 2018).

7.6 Browse to NWS Project Relative to Global GHG Emissions

While it is not feasible to directly correlate the potential impact of the proposed Browse to NWS Project GHG emissions on receptors (be that impact negative or positive in the case of replacing higher carbon fuels), the direct contribution of the proposed Browse to NWS Project GHG lifecycle emissions (including NWSJV Scope 1 emissions) to global emissions can be estimated. Table 7-13 shows the estimated average GHG contribution compared to five United Nations Environment Program NDCs Scenarios. As per Section 7.4.5, the proposed Browse to NWS Project total lifecycle emissions are anticipated to be less than if equivalent energy were to be generated from coal.

Table 7-13 Proposed Net Browse to NWS Project average GHG lifecycle emissions contribution to NDC Scenarios

Lifecycle emissions	Total global GHG emissions (MTCO$_2$-e/ year) (UN Environment, 2018)	Proposed Browse to NWS Project Scope 1 (Net average (upstream and downstream) of 4.8 MtCO$_2$-e/ year (%))	Proposed Browse to NWS Project total lifecycle emissions (Average of 36.8 MtCO$_2$-e/ year (%))
2030 (no policy baseline)	65,000	0.01	0.06
2030 (current policy scenario)	59,000	0.01	0.06
2030 (2°C pathway)	40,000	0.01	0.09
2030 (1.5°C pathway)	24,000	0.02	0.15

It should be noted that the 2030 emissions forecasts are United Nations Environment Program estimates only and total global GHG emissions reflect anthropogenic emissions only.

Woodside Energy Ltd is operator for and on behalf of a number of Joint Ventures and is currently proposing other developments in the region. For more information on greenhouse gas emissions associated with each development, please refer to:

- North West Shelf Project Extension ERD (EPA 2186, EPBC 2018/8335)
- Scarborough OPP (NOPSEMA A679881)
- Pluto LNG Development (EPA 1632, EPBC 2006/2968).

Please note, greenhouse gas emissions associated with the developments listed above is not addressed further in this draft EIS/ERD, as they are assessed in their respective assessment documents.

Under the Paris Agreement, Australia has a target of reducing emissions by 26-28 per cent below 2005 levels by 2030. Australia stated in its Nationally Determined Contribution that it would develop its target into an emissions budget covering the period 2021-2030. The cumulative emission budget for this period is 4800 MT to reach the 26% reduction target (DoEE, 2018). Scope 1 and 2 GHG emissions from the upstream component of the proposed Browse to NWS Project are expected to contribute to 0.8 % of this cumulative emissions budget. The Australia's emissions projections 2018 report provides an indicative summary of how Australia is tracking to achieve its Nationally Determined Contribution of 26 to 28 per cent below 2005 levels in 2030. Projected emissions to 2030 from the LNG sector (direct combustion and fugitive) are included in the methodology used to underpin these projections. The methodology is based on an export capacity of 80MPTA of LNG in 2020 with the addition of one new LNG train in the mid-2020s.

The emissions reduction task to achieve the 2030 target is currently 328 MT CO_2-e. The Australian government has outlined a plan to closing this gap in the Climate Solutions Package.

7.7 Management and Mitigation of GHG Emissions

7.7.1 Processing Emissions

The following key energy efficiency and emissions reductions measures have been incorporated into the design of the proposed Browse to NWS Project. The associated emissions reductions achieved by these initiatives have been estimated and presented in square brackets next to each initiative. Note that estimates are presented as being across two FPSO facilities, operating at maximum pipeline throughout (i.e. the "max" scenario). The measures are:

- waste heat recovery units on gas turbines [0.70 MT CO_2-e/annum]
- active heating system used to prevent hydrate formation in flowlines avoiding the requirement for an energy intensive MEG regeneration plant [0.20 MT CO_2-e/annum]
- batteries for peak power supply [0.10 MT CO_2-e/annum]
- efficient aero-derivative gas turbines [0.02 MT CO_2-e/annum]
- use of nitrogen to purge the flare stack rather than hydrocarbon gas [expected less than <0.1 MT CO_2-e/annum].

Note that without the above key energy efficiency and emissions reductions measures, the Scope 1 forecast gross emissions associated with the Browse to NWS Project would be higher. By saving approximately up to 1 MT of CO_2-e on average per year, this has reduced the expected average annual net Scope 1 Project emissions from up to 5.8 MT CO_2-e to 4.8 MT CO_2-e per year and saved 31 MT CO_2-e of Scope 1 emissions over the expected life of the Project.

To compare processing emissions for upstream facilities, it is important to recognise that for upstream developments such as the Browse to NWS Project, the amount of energy required to process and export the gas is principally driven by:

- The amount of CO_2 that needs to be removed from the gas stream, as the process to remove the CO_2 from the gas stream is heat-intensive.
- The distance that the gas needs to be transported, as the amount of energy required to achieve the required gas export rate and pressure increases as the distance increases.

As the above variables are highly reservoir and location specific it is difficult to draw comparisons between projects. However, as Browse has a relatively high reservoir CO_2 content, and the Browse Trunkline is approximately 900 km long to NWS facilities, then the most comparable facilities are those with:

- Long pipelines or pipeline networks to reach the downstream LNG facility (i.e. have similar compression requirements).
- High reservoir CO_2 content, and therefore either need to consume energy to remove the CO_2 or consume more energy to export it to the downstream LNG facility.

On this basis the two most comparable facilities identified are the proposed Borossa-Caldita project and the Ichthys project, due to somewhat similar reservoir CO_2 content and distance to the LNG facilities.

For completeness based on distance to LNG facilities an unconventional reservoir for APLNG has also been selected due to its substantial gas gathering network and distance to LNG facilities. **Figure 7-4** provides benchmarking between the processing emissions for the proposed Browse FPSOs and identified comparable facilities in Australia, to demonstrate the effectiveness of the upstream design in consuming energy to process the gas stream and pressurise it for export. Intensity has been calculated on a fuel gas use only and **Figure 7-4** does not include the reservoir CO_2 emissions. The CO_2 percentage has been provided as an indicator of the likely energy expenditure on CO_2 removal for each project. Note the data used to calculate other operators' emissions intensity is of varying quality and has been sourced from regulatory authorisations (i.e. environmental impact statements, environmental review documents and management plans), actual emissions intensity of facilities in operation may differ from that presented.

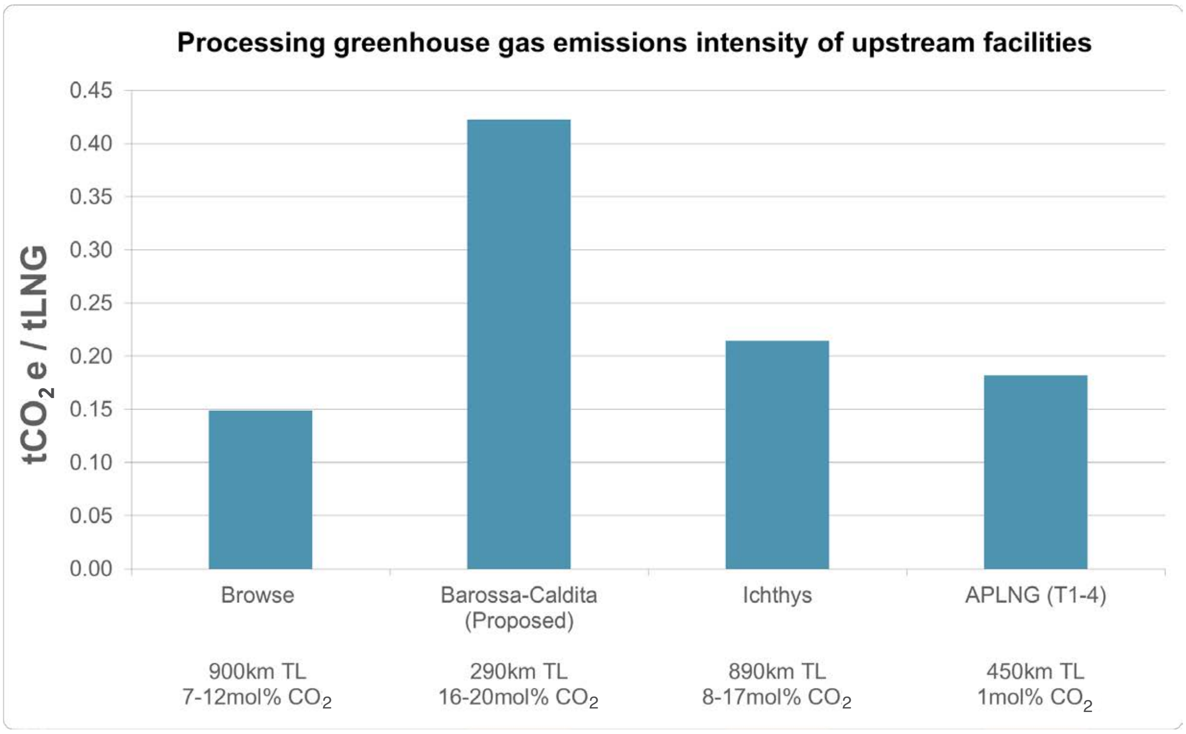

*Figure 7-4 Processing CO_2-e Emissions Intensity of Comparable Upstream Facilities**

* *Note all emissions data for Australian facilities has been sourced from regulatory authorisations (i.e. environmental impact statements, environmental review documents and management plans)*

Mitigation and management measures associated with anticipated processing emissions for the NWS Extension Project are described in the NWSJV's 'North West Shelf Project Extension ERD' (EPA 2186, EPBC 2018/8335).

7.7.2 Carbon Credits

Under the National Greenhouse and Energy Reporting scheme, the BJV will be required to surrender Australian carbon credit units (ACCUs) to offset emissions over the SGM baseline. Offsets may be secured by the Operator (Woodside) or separately by individual Joint Venture Participants for their equity emissions. Offsetting opportunities that will be investigated include industry methods or land-based solutions for carbon sequestration, which may include savanna burning, environmental planning, native tree planting and human induced land restoration.

By way of example, Woodside has recently entered into a Heads of Agreement (HoA) with Greening Australia to co-create large-scale, native tree planting projects that generate quality carbon offsets. Woodside and Greening Australia will assess environmental and economic viability of a range of opportunities across Australia, with an initial focus in Western Australia. The agreement is scalable and the first phase will involve planting up to 5000 hectares in 2020, in an ecologically and scientifically responsible manner, primarily in Western Australia.

The generation of GHG offsets through approved and validated carbon farming methodologies is a significantly lower risk and more cost-effective solution than geosequestration of Browse reservoir CO_2. GHG offsets also offer co-benefits resulting from the additional ecosystem services provided when carbon is bio-sequestered, as well as social, economic and environmental benefits (e.g. improvements to air quality, employment opportunities in remote communities or provision of additional habitat for fauna).

It is also anticipated that there will be emissions associated with the proposed processing of Browse feed gas through third party infrastructure as described above in Section 7.7.1. The BJV is a party seeking long term processing services from the NWSJV. It is anticipated that these emissions will be mitigated and managed by the NWSJV in accordance with regulatory requirements applicable to the proposed NWS Extension Project. It must be noted that the NWSJV will not solely process Browse gas as existing NWSJV reserves will continue to be produced, and there is potential for additional resource owners to secure processing services with NWSJV. The BJV is presently negotiating commercial arrangements with the NWSJV regarding the provision of gas processing services.

7.7.3 Geosequestration

There are two main CO_2 emission streams (Figure 7-2) that could be considered for geosequestration – the AGRU and emissions from the gas turbines. This would involve the capture of CO_2 at the outlet of a major gas stream, such as the vent stream from the offshore AGRU or from the exhaust stream of the gas turbines. While the offshore AGRU stream is predominantly CO_2, the gas turbine exhaust stream would likely require further processing to strip the CO_2 from the stream for capture. Further processing of the exhaust stream would add significant complexity and is prohibitive in an offshore environment where space is restricted. LNG projects that do geosequester typically geosequester the AGRU vent stream only.

Once CO_2 emissions are captured, the stream would then be pressurised and re-injected into a suitable subsurface disposal target. Over 30 potential re-injection sites near the proposed Browse Development Area were identified and screened based on their cost, subsurface suitability and risk profile (including non-technical risks such as gaining access to land, complexity of commercial agreements, etc.).

Based on this screening, the Calliance reservoir was identified as a potentially viable re-injection site. As the Calliance reservoir will be a producing gas and condensate field, its use as a geosequestration site would carry significant technical, operational and safety risks. These include:

- Technical feasibility as offshore geosequestration at the required scale is unproven.
- Subsurface inject-ability risk; by reinjecting into a producing reservoir, there is a risk that more CO_2 is produced from the reservoir (i.e. the CO_2 ‘recycles’), reducing the impact of geosequestration as a mitigation measure.
- Safety risk during operations as an additional safety hazard (CO_2 asphyxiation) is added to the FPSO, associated with additional processing and compression.

Geosequestration is, therefore, a high risk, high cost mitigation option for Browse reservoir CO_2.

7.8 Acceptability Assessment

An assessment of the acceptability of proposed Browse to NWS Project GHG emissions is provided in Table 7-10.

The assessment of acceptability has been undertaken in consideration of:

- principles of ESD as defined in Section 3A of the EPBC Act
- MNES Significant Impact Guidelines (EPBC Act)
- WA EPA Environmental Factors and Objectives (EP Act)
- other aspect or receptor requirements including State, Federal and international standards, laws, policies and guidelines, including management plans and conservation advice
- external requirements
- internal requirements.

Further details in relation to these criteria are set out in Chapter 6.

Overall, in the context of Australia’s international commitments and local legislation and policy, it is considered that given the proposed mitigation of emissions, safeguard mechanism obligations and the importance of gas as a clean and reliable source of energy in the current and future energy mix, GHG emissions from the proposed Browse to NWS Project are acceptable.

Table 7-14 Acceptability Assessment – GHG emissions

Acceptability Assessment
Principals of ESD As described in Section 7.4.5 the provision of clean and reliable energy is paramount to the lifting of worldwide living standards. As a clean and reliable energy source, gas is expected to play a key role in the future energy mix (as a partner to renewables). In addition, gas has the potential to contribute significantly to the reduction in global GHG emissions by displacing higher carbon intensive power generation (e.g. coal burning). Given the importance of gas in the current and future energy mix, the planned emissions mitigation and offsetting (Section 7.7) to reduce GHG emissions; and the broader socio-economic benefits to both Australia and the State of Western Australian of the proposed Browse to NWS Project, it is considered that the principals of ESD have been met. **Conclusion: Acceptable**
Significant impacts as defined by the MNES Significant Impact Guidelines No direct impacts to listed threatened and migratory species, threatened ecological communities, the Commonwealth Marine Area or the environment are predicted to occur as a result of GHG emissions from the proposed Browse to NWS Project. Climate change induced impacts to listed or threatened species, threatened ecological communities, the Commonwealth Marine Area or the environment resulting from the proposed Browse to NWS Project are difficult to predict and likely immeasurable. Global GHG emissions will continue to have an effect on trends in receptor condition and potential impacts to listed threatened and migratory species, threatened ecological communities or the Commonwealth Marine Area or environment may occur as a result (Section 7.5). As a stand-alone project, however, taking into account all planned emissions reduction and offsetting measures (Section 7.7), it is estimated that Scope 1 and 3 emissions from the proposed Browse to NWS Project could contribute in the range of 0.06% to 0.15% global GHG emissions depending on the NDC scenario considered (Table 7-13). As a stand-alone project, GHG emissions from the proposed Browse to NWS Project will not have a significant impact (as defined by the MNES Significant Impact Guidelines) on listed threatened species or migratory species, threatened ecological communities, the Commonwealth Marine Area or the environment. The proposed Browse to NWS Project has proposed a GHG Abatement Plan to continuously review mechanisms to mitigate and manage GHG emissions and compliance with NGER/SGM baseline requirements through ACCUs to offset anticipated excess emissions over baseline. Further, as discussed in Section 7.7.1, gas use is not only consistent with the WEO's SDS but required to achieve the goals of climate change mitigation, air quality improvements and energy access. As such, the proposed Browse to NWS Project may potentially have a positive impact via the reduction of global emissions with potential subsequent reduction in impacts to sensitive receptors resulting from climate change. However, this is acknowledged as being uncertain in a global context and therefore is appropriately categorised as gas having benefits over the use of coal in generating electricity. **Conclusion: Acceptable**

Acceptability Assessment

WA EPA Environmental Objectives

No direct impacts to benthic communities and habitats, marine environmental quality or marine fauna are predicted to occur as a result of GHG emissions from the proposed Browse to NWS Project.

Climate change induced impacts to benthic communities and habitats, marine environmental quality or marine fauna resulting from the proposed Browse to NWS Project are difficult to predict and likely immeasurable. Global GHG emissions will continue to have an effect on trends in receptor condition and potential significant impacts to benthic communities and habitats, marine environmental quality or marine fauna may occur as a result (**Section 7.5**). As a stand-alone project however, taking into account all planned emissions reduction and offsetting measures (**Section 7.7**), it is estimated that Scope 1 and 3 emissions from the proposed Browse to NWS Project will contribute in the range of 0.06% to 0.15% of global GHG emissions depending on the NDC scenario considered (**Table 7-13**). As such, it is not considered credible that as a stand-alone project, GHG emissions from the proposed Browse to NWS Project will significantly impact benthic communities and habitats, marine environmental quality or marine fauna and, as such, the relevant EPA objectives for these environmental factors will be met.

Further, as discussed in **Section 7.7.1**, gas has the potential to contribute significantly to the reduction in global GHG emissions by displacing higher carbon intensive power generation (e.g. coal-gas energy switch). As such, the proposed Browse to NWS Project may potentially have a positive impact via the reduction of global GHG emissions, with potential subsequent reduction in impacts to sensitive receptors resulting from climate change. However, this is acknowledged as being uncertain in a global context and therefore is appropriately categorised as gas having benefits over the use of coal in generating electricity.

Conclusion: Acceptable

External Context

GHG emissions from petroleum developments was identified as a stakeholder issue during stakeholder engagement (**Chapter 4**). It is considered that the proposed mitigation and management of GHG emissions and likely NGER/SGM offset obligations address this issue.

Conclusion: Acceptable

Internal Context

Woodside has a Climate Change Policy and a Woodside Management System (**Chapter 8**). For more details on the Policy, see https://www.woodside.com.au/sustainability/climate-change.

As part of the management of the proposed Browse to NWS Project, a GHG Abatement Plan will be developed and implemented to achieve the environmental objective (**Section 7.2** and **Chapter 8**).

Conclusion: Acceptable

Other Requirements

The Paris Agreement

The targets set by the Paris Agreement are detailed in **Section 7.3.1**. As a clean and reliable energy source (described in **Section 7.7.1**), gas is expected to play a key role in the future energy mix and it has the potential to contribute to the reduction in global GHG emissions by displacing higher carbon intensive power generation (e.g. coal burning).

Australia's Nationally Determined Contributions

Australia's NDC is for an absolute economy-wide emissions reduction by 2030. Given the emission estimates and the likely NGER/SGM offset obligations, it is not expected that the proposed Browse to NWS Project will prevent Australia meeting its NDC commitments.

Safeguard Mechanism (SGM)

Woodside is committed to its obligations under the NGER/SGM. Based on current regulatory NGER Act SGM emissions baseline requirements, it is anticipated that CO_2 emissions derived from the Browse reservoirs will contribute to emissions from the proposed Browse to NWS Project, exceeding any anticipated facility baseline. This would likely result in SGM offset obligations, which at this stage are anticipated to be met in the form of ACCUs.

It is also anticipated that there will be emissions associated with the processing of Browse feed gas through third party infrastructure as described above in **Section 7.4.1**. It is anticipated that these emissions will be mitigated and managed by the NWSJV in accordance with regulatory requirements applicable to the proposed NWS Extension Project.

Conclusion: Acceptable

CHAPTER 8

ENVIRONMENTAL MITIGATION, MANAGEMENT AND MONITORING

8. ENVIRONMENTAL MITIGATION, MANAGEMENT AND MONITORING

8.1 Introduction

This chapter describes how Woodside intends to implement the environmental management program throughout the life of the proposed Browse to NWS Project. It demonstrates the mitigation and management approach that Woodside will use to avoid or minimise environmental impacts and risks identified in this draft EIS/ERD to an acceptable level.

8.2 Woodside's Health, Safety and Environmental Management System

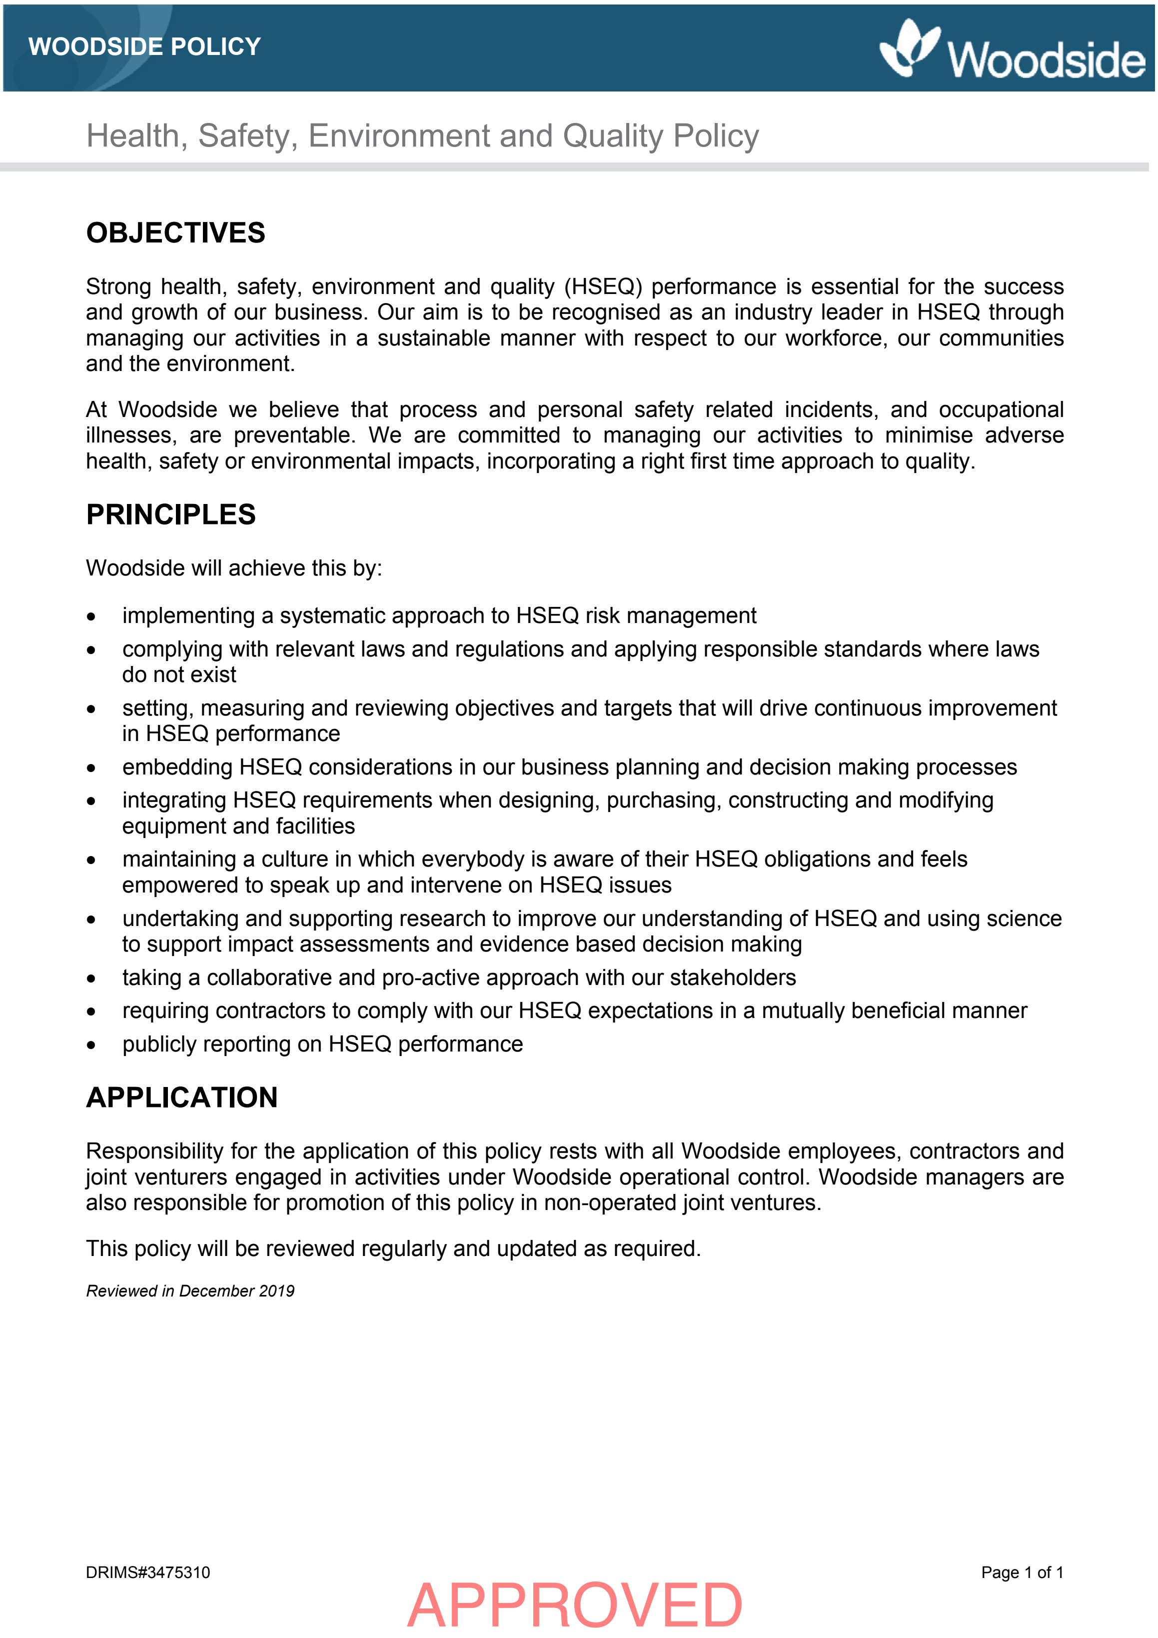
8.3 Overview

The Woodside Management System (WMS) defines how Woodside will deliver its business objectives and the boundaries within which all Woodside employees and contractors are expected to work. The WMS consists of a mission statement, policies, decision making committees, frameworks of authorities and standards, that when applied, provide management, governance and assurance. Environmental management is one of the components of the overall WMS.

8.4 Health, Safety, Environment and Quality Policy

Within the WMS, the overall direction for Environment is set through Woodside's corporate Health Safety, Environment and Quality Policy (**Figure 8-1**). The policy provides a public statement of Woodside's commitment to minimising adverse effects on the environment from its activities and to improving environmental performance. It sets out the principles for achieving the objectives for the environment and how these are to be applied. The policy is applied to all Woodside's activities, and all employees, contractors and Joint Venture partners engaging in activities under Woodside operational control.

In addition, Woodside's Climate Change Policy (refer to **Chapter 7**) demonstrates a commitment to be part of a solution to climate change. This includes promoting and pursuing a culture of energy efficiency and improving resource use in design and operation.



WOODSIDE POLICY

Health, Safety, Environment and Quality Policy

OBJECTIVES

Strong health, safety, environment and quality (HSEQ) performance is essential for the success and growth of our business. Our aim is to be recognised as an industry leader in HSEQ through managing our activities in a sustainable manner with respect to our workforce, our communities and the environment.

At Woodside we believe that process and personal safety related incidents, and occupational illnesses, are preventable. We are committed to managing our activities to minimise adverse health, safety or environmental impacts, incorporating a right first time approach to quality.

PRINCIPLES

Woodside will achieve this by:

- implementing a systematic approach to HSEQ risk management
- complying with relevant laws and regulations and applying responsible standards where laws do not exist
- setting, measuring and reviewing objectives and targets that will drive continuous improvement in HSEQ performance
- embedding HSEQ considerations in our business planning and decision making processes
- integrating HSEQ requirements when designing, purchasing, constructing and modifying equipment and facilities
- maintaining a culture in which everybody is aware of their HSEQ obligations and feels empowered to speak up and intervene on HSEQ issues
- undertaking and supporting research to improve our understanding of HSEQ and using science to support impact assessments and evidence based decision making
- taking a collaborative and pro-active approach with our stakeholders
- requiring contractors to comply with our HSEQ expectations in a mutually beneficial manner
- publicly reporting on HSEQ performance

APPLICATION

Responsibility for the application of this policy rests with all Woodside employees, contractors and joint venturers engaged in activities under Woodside operational control. Woodside managers are also responsible for promotion of this policy in non-operated joint ventures.

This policy will be reviewed regularly and updated as required.

Reviewed in December 2019

APPROVED

Figure 8-1 Woodsides Corporate Health, Safety, Environment and Quality Policy

8.5 Woodside's Management System

The WMS provides a structured framework of documentation to set common expectations governing how all employees and contractors at Woodside will work. WMS documentation, which is comprised of four elements (Compass & Policies; Expectations; Processes & Procedures; and Guidelines) is outlined below and illustrated in Figure 8-2:

- **Compass & Policies:** Set the enterprise-wide direction for Woodside by governing behaviours, actions and business decisions and ensuring Woodside meets its legal and other external obligations.
- **Expectations:** Set essential activities or deliverables required to achieve the objectives of the Key Business Activities and provide the basis for development of processes and procedures.
- **Processes & Procedures:** Processes identify the set of interrelated or interacting activities which transforms inputs into outputs, to systematically achieve a purpose or specific objective. Procedures specify what steps, by whom and when required to carry out an activity or a process.
- **Guidelines:** Provide recommended practice and advice on how to perform the steps defined in procedures, together with supporting information and associated tools. Guidelines provide advice on how activities or tasks may be performed; information that may be taken into consideration; or how to use tools and systems.

The WMS is organised within a business process hierarchy based upon key business activities to ensure the system remains independent of organisation structure and is globally applicable and scalable as required. These key business activities are grouped into management, support and value stream activities as shown in Figure 8-3. The value stream activities capture, generate and deliver value through the exploration and production lifecycle. The management activities influence all areas of the business, while support activities may influence one or more value stream activities.

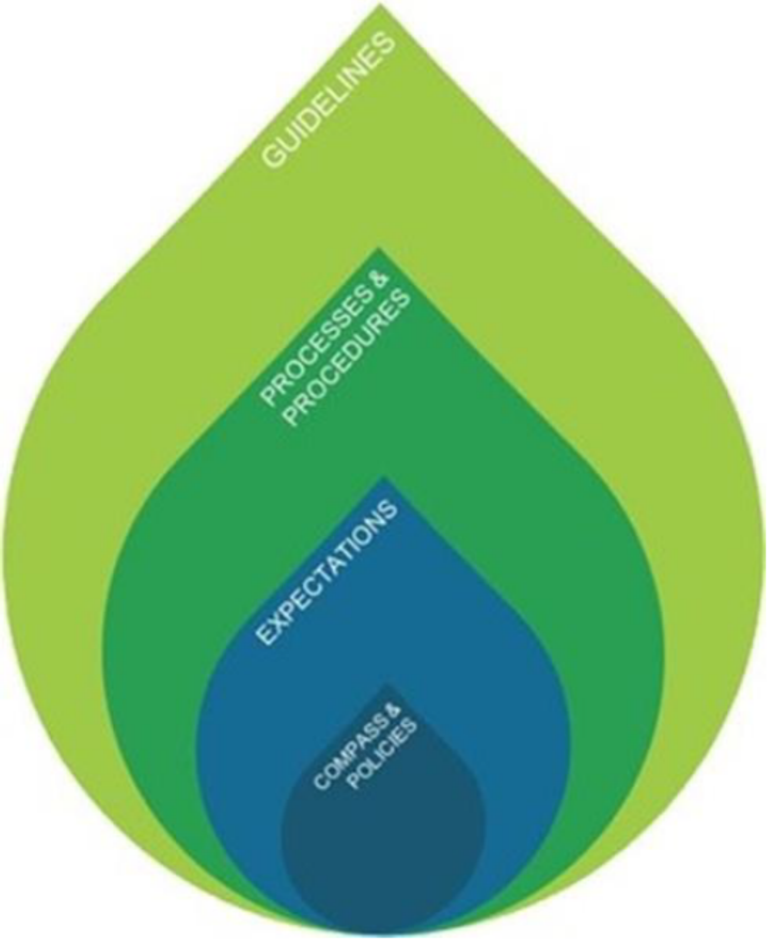

Figure 8-2 The Four Major Elements of the WMS Seed

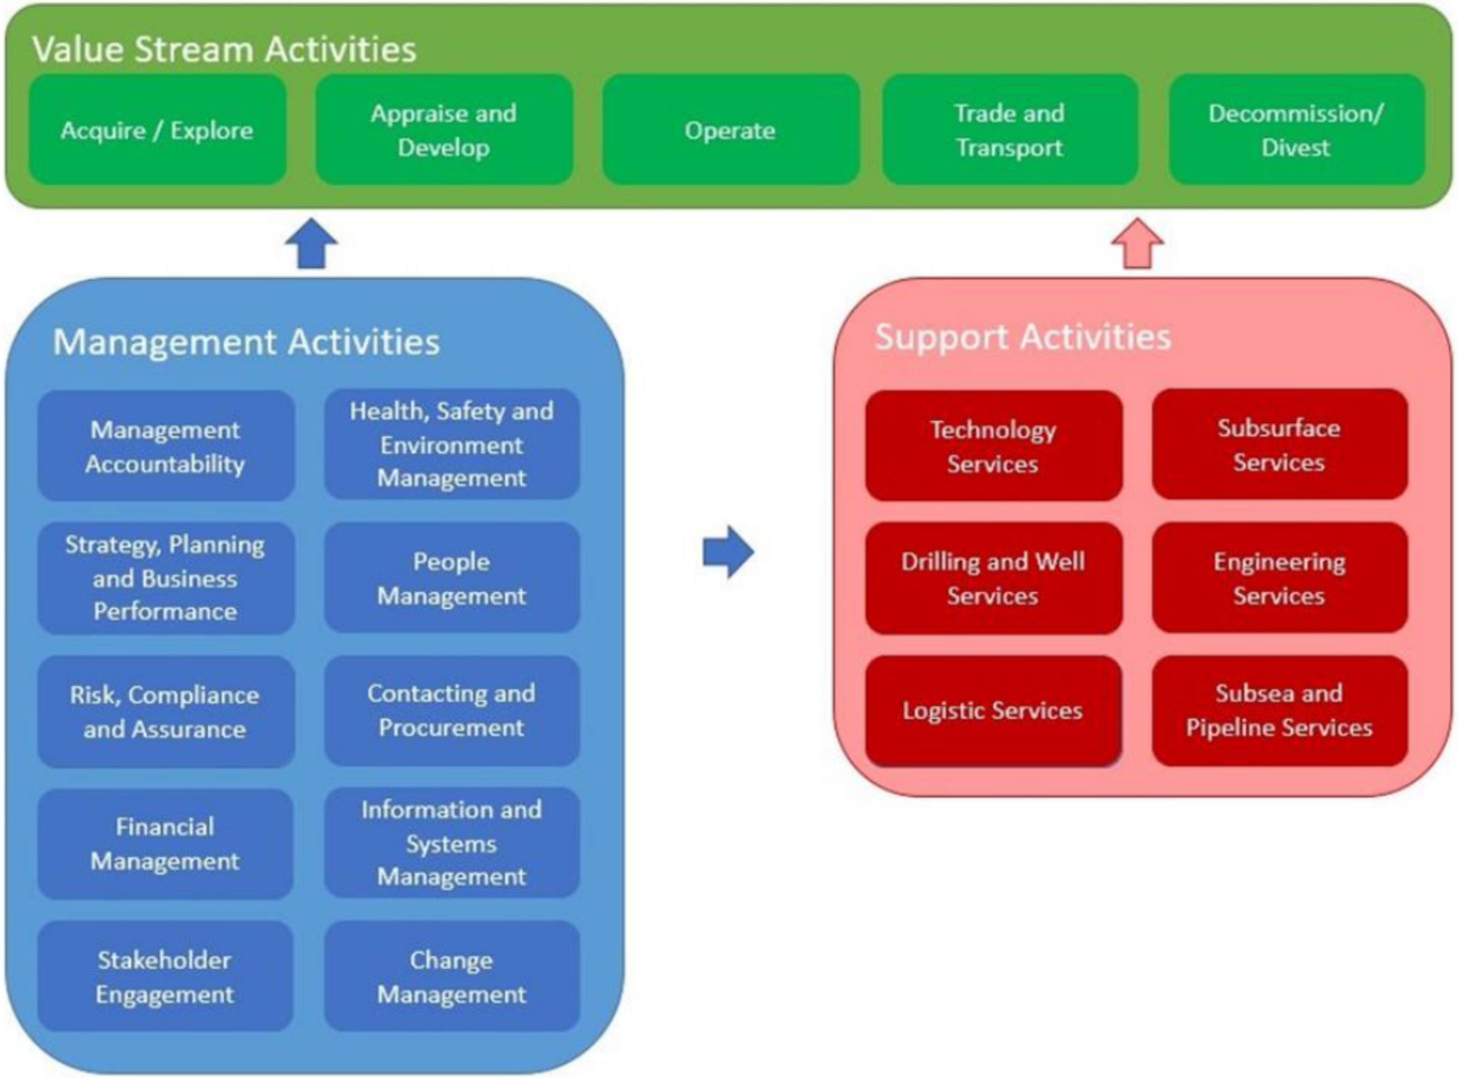

Figure 8-3 The WMS Business Process Hierarchy

8.6 Relationship of the WMS and the draft EIS/ERD

The objectives under the WMS define the mandatory performance requirements that apply to all Woodside activities, and the performance of its employees and contractors within their area of responsibilities. The management commitments made in this draft EIS/ERD and subsequent Environment Plans will be implemented through the WMS and supplemented where required by documentation specific to the proposed Browse to NWS Project.

8.7 Planning framework

Woodside sets environmental performance requirements through the life-cycle of projects and operations. This approach is based on:

- a robust environmental risk-management process
- credible and defensible science to underpin this approach
- strong relationships with local and international researchers
- ongoing stakeholder engagement
- transparency of our environmental knowledge.

Credible and defensible science is core to Woodside's environmental management approach and processes. Woodside's strong capability in environmental studies enables the acquisition of environmental data critical to inform impact assessments and decision making. Furthermore, strong relationships, sound research and transparency are the key elements of Woodside's approach to the environment.

Woodside has an established methodology that identifies impacts and risks and assesses the potential consequence of an activity. This methodology mandates that a risk hierarchy of controls be applied to management measures that are identified. This approach identifies ways to eliminate or avoid an impact before measures are considered to reduce or minimise it. The management measures include, as a minimum, those that are considered good international industry practice.

The end result of this risk-based process is that the residual impacts and risks of an activity are at a level considered to be acceptable.

8.8 Environmental record of person(s) undertaking the Proposed Action

8.8.1 Record of environmental management

Woodside, as operator for and on behalf of the BJV, believes excellence in environmental performance is essential to our business success worldwide and is compatible with balancing the economic, social and environmental needs of sustainable development.

Woodside employs a structured approach to the management of the environment via the formal and documented WMS. Through policies, processes, procedures and standards the WMS requires that impacts from Woodside's operations are either avoided or kept to ALARP. It also drives continuous improvement in the company's environmental performance.

Woodside's commitment to responsible environmental management was recognised by the Australian Petroleum Production and Exploration Association (APPEA) as the recipient of the Environment Excellence Award in 2009, 2012, 2015, 2016, 2017 and 2019. Woodside was recognised in 2009 for appraisal activities at Scott Reef, including environmental research undertaken at Scott Reef in association with the Maxima 3D marine seismic survey and the Gigas 2D Pilot Ocean Bottom Cable marine seismic survey. This recognition was for Woodside's approach to undertaking activities in a highly sensitive environmental setting. The 2012 and 2017 APPEA Environment Awards recognised Woodside's partnerships with AIMS and Western Australian Museum (WAM). These long-term relationships have contributed shared scientific knowledge to academic, government, industry and the broader community's understanding of biodiversity and ecological function in WA's tropical marine ecosystems.

8.8.2 Past or present procedures

Woodside has not been subject to any proceedings, either past or present, under a Commonwealth or State law for the protection of the environment or the conservation and sustainable use of natural resources.

8.9 Environmental management and mitigation

8.9.1 Overview

As part of the development of this draft EIS/ERD, management and mitigation measures have been identified and will be implemented to reduce the level of impact and risk of the proposed Browse to NWS Project to an acceptable level in consideration of the EPBC Act, EP Act and other relevant policy instruments (**Chapter 6**). This includes any practices that will reduce the impacts and risks in order to meet the identified environmental objectives, any relevant legal requirements (related specifically to the impact/risk), internal company requirements and any practices that will be adopted to manage stakeholder concerns identified through the consultation process. It should be noted that further review and potential adoption of additional controls will be undertaken in subsequent phases of the project, such as during the preparation of Environment Plans for activities under the scope of the approved action.

In accordance with Woodside's risk procedures and processes and for the purpose of the draft EIS/ERD, where an impact or risk has been assessed to be acceptable, no further management beyond legislative requirements and industry codes and standards will be required. Where the impact or risk level is not acceptable, additional management and mitigation measures have been considered.

The following framework tools have been applied, as appropriate, to assist with identifying appropriate management and mitigation measures:

- Good Industry Practice – identifies further engineering control standards and guidelines which may be applied by Woodside in addition to those required to meet the legislation, codes and standards.
- Professional Judgement – uses relevant personnel with the knowledge and experience to identify alternative controls.

Using these tools, the following hierarchy of controls have been used to identify appropriate management and mitigation measures for the proposed Browse to NWS Project:

- eliminate the risk by removing the hazard
- substitute a hazard with a lesser one
- prevent a credible impact from occurring by implementing additional engineering control measures
- reduce the magnitude of a credible impact by implementing additional engineering control measures (e.g. solids control equipment onboard MODU to manage cuttings discharge)
- mitigate the credible impact on the environment by reducing the extent, scale, duration of impact (e.g. bunding, oil spill booms, relief well)
- emergency response and contingency planning to facilitate recovery from the credible impact of an event.

Environmental objectives and proposed mitigation and management measures are presented in **Chapter 6**.

8.9.2 Central management and monitoring commitments

The central management and monitoring commitments are detailed in **Chapter 6** and summarised in **Chapter 1** and **Chapter 9**.

The measures presented in this draft EIS/ERD will be incorporated into activity-specific Environment Plans (**Section 8.14.1.1**) to be submitted for acceptance by NOPSEMA for Commonwealth waters and DMIRS for State waters, prior to the activity commencing where required.

8.10 Management Plans

Under the environmental management framework, specific environmental management plans will be prepared for the proposed Browse to NWS Project. These will include activity-specific Environment Plans (**Section 8.14.1.1**) and an Environmental Quality Management Plan applicable to the State Proposal Area (**Section 8.14.1.2**). Contractors will also be required to prepare environmental management plans for Woodside approval that detail how the project requirements will be met.

8.10.1 Environment Plans

8.10.1.1 Environment Plans

Accepted activity-specific Environment Plans will be required under both the OPGGS (E) Regulations (for Commonwealth waters) and the Petroleum (Submerged Lands) (Environment) Regulations 2012 (for State waters).

The Environment Plans must be appropriate for the nature and scale of the activity and describe the activity, the existing environment, details of environmental impacts and risks and the control measures for the activity. In addition, the Environment Plans must include an implementation strategy to demonstrate that the impacts and risks can be managed to ALARP and to describe how appropriate environmental performance outcomes, standards and measurement criteria outlined in the Environment Plans will be met. The Environment Plans must also provide a summary of all consultation undertaken with relevant persons.

The Environment Plans required in support of the proposed Browse to NWS Project will address activities related to:

- drilling development wells in both State and Commonwealth waters
- installing, commissioning and operating subsea

infrastructure in both State and Commonwealth waters

- installing, commissioning and operating the FPSO facilities (Commonwealth waters only)
- installing, commissioning and operating the BTL and Inter-field spur line (Commonwealth waters only)
- decommissioning activities at the end of the proposed Browse to NWS Project life.

Environment Plans will be supported by appropriate Oil Pollution Emergency Plans (OPEPs) and Operational and Scientific Monitoring Programs (OSMPs), which are required as a part of an Environment Plan's implementation strategy, noting that these may be developed to support a range of activities or phases of a project. The Environment Plans will be submitted for acceptance by NOPSEMA (Commonwealth waters) or DMIRS (State waters) before the activities listed above can commence.

8.10.1.2 Environmental Quality Management Plan (State Proposal Area)

As recommended in the WA EPA Technical Guidance – Protecting the Quality of Western Australia's Marine Environment (EPA, 2016), an Environmental Quality Management Plan (EQMP) will be prepared and implemented for the Proposal. The EQMP will only apply to the State Proposal Area. The EQMP will be developed using the principles and approaches outlined in the EPA's technical guidance. Refer to State ERD (**Chapter 10, Appendix B**).

8.10.1.3 Environmental Offset Plan

In the event that impacts cannot be avoided or mitigated to an acceptable level, an Environmental Offset Plan will be developed. Offsets associated with GHG emissions are specifically addressed in **Chapter 7** and will not be included in this offset plan.

The Environmental Offset Plan will provide details of offsets proposed to compensate for residual impacts on EPBC listed species, including the following:

- the type of offsets proposed
- the extent to which the proposed offset actions correlate to, and adequately compensate for, the impacts to EPBC listed species
- for proposed land-based offsets, the suitability of the location of proposed offset sites, including the current land tenure and method of securing and managing the offset for the life of the impact
- for non-land-based offsets, details of the proposed offset and how it will compensate for the proposal's residual significant impacts
- the conservation gains to be achieved by the offset (for example, positive management strategies that improve the site, or how the future loss, degradation or damage of the protected matter will be averted or mitigated)
- the time it will take to achieve the proposed conservation gains
- the level of certainty that the proposed offset will be successful.

The Environmental Offset Plan would be developed in accordance with the EPBC Act Environmental Offsets Policy (Commonwealth of Australia, 2012). (Commonwealth of Australia, 2012) or other relevant legislation or policy applicable at the time.

8.10.1.4 Environmental management Implementation approach

Roles and Responsibilities

Key roles and responsibilities for Woodside and Contractor personnel in relation to the implementation of controls identified in this draft EIS/ERD and subsequent Environment Plans are described in **Table 8-1**. In addition to these identified roles, it is the responsibility of all Woodside employees and contractors to implement the Woodside Corporate Health, Safety, Environment and Quality Policy in their areas of responsibility and that the personnel are suitably trained and competent in their respective roles.

Table 8-1 Roles and Responsibilties

Title (role)	Environmental Responsibilities
Woodside Project Manager	+ Verify implementation of the receptor or aspect-specific environmental management plans related to the proposed Browse to NWS Project. + Verify systems and procedures are in place to manage the activity so it is undertaken as per the relevant standards and commitments in this draft EIS/ERD and subsequent Environment Plans. + Verify that contractors meet environmental related contractual obligations.
Woodside Delivery Manager (FPSO, SURF, BTL)	+ Verify that environment expectations are understood by team members in line with the commitments set out in this draft EIS/ERD and subsequent Environment Plans. + Communicate environment performance, relevant information and Lessons Learnt to team members and contractors. + Verify application of contractor's management of environment requirements, in accordance with the draft EIS/ERD and subsequent Environment Plans.
Woodside Environment Adviser	+ Track and report on compliance against environmental commitments as per the requirements of this draft EIS/ERD and subsequent Environment Plans. + Prepare environmental components of relevant Induction Package. + Provide advice to Woodside personnel and contractors to assist them with understanding their environment responsibilities.
Woodside Drilling Superintendent	+ Verify that the drilling program meets the requirements detailed in this draft EIS/ERD and subsequent Environment Plans.
Woodside Drilling and Subsea Engineers	+ Verify that all chemicals and drilling fluids proposed to be used for Browse drilling and completion activities are assessed and approved as per the requirements of the draft EIS/ERD and subsequent Environment Plans.
Woodside Corporate Affairs Adviser	+ Prepare and implement the Stakeholder Consultation Plan for the proposed Browse to NWS Project activities.
Woodside Marine Assurance Superintendent	+ Conduct relevant audits and inspections to confirm vessels are compliant with relevant Marine Orders and Woodside Marine Charters Instructions requirements to meet safety, navigation and emergency response requirements.
Offshore Installation Manager (OIM) (MODU, FPSOs)	+ Verify that the WMS is implemented. + Verify that personnel receive an environmental induction that meets the requirements specified in this draft EIS/ERD and subsequent Environment Plans.
Woodside Site Representative	+ Verify that proposed Browse to NWS Project scopes are undertaken as detailed in this draft EIS/ERD and subsequent Environment Plans. + Verify the management measures detailed in this draft EIS/ERD and subsequent EPs are implemented on the MODU/FPSO/Vessels.
Offshore HSE Adviser/ Vessel HSE Advisers	+ Support Woodside Site Representatives to ensure that the controls detailed in this draft EIS/ERD and subsequent Environment Plans. relevant to offshore activities are implemented and assist in collection and recording of evidence of implementation. + Confirm that periodic environmental inspections/reviews are completed and corrective actions from inspections are developed, tracked and closed out in a timely manner.
Vessel Master	+ Verify that the vessel management system and procedures are implemented. + Verify that personnel commencing work on the vessel receive an environmental induction that meets the requirements specified in this draft EIS/ERD and subsequent Environment Plans.
Vessel Logistics Coordinators	+ Confirm that waste is managed appropriately on the relevant support vessels as per the requirements of this draft EIS/ERD and subsequent Environment Plans.
Contractor Project Manager	+ Verify that activities are undertaken in accordance with this draft EIS/ERD and subsequent EPs, as detailed in the Woodside approved Contractor's Environmental Management Plans. + Verify that personnel commencing work on the project receive a relevant environmental induction that meets the requirements of this draft EIS/ERD and subsequent Environment Plans.

Emergency Preparedness and Response

Woodside will have an Emergency Response Plan (ERP) in place for all petroleum activities associated with the proposed Browse to NWS Project. The ERP will provide procedural guidance specific to the activity to control, coordinate and respond to an emergency or incident, including hydrocarbon spills.

Under Regulations 14(8) of the OPGGS (E) Regulations, the implementation strategy for Environment Plans in Commonwealth waters must contain an OPEP and provide for the updating of the OPEP. Regulation 14(8AA) outlines the requirements for the OPEP, which must include adequate arrangements for responding to and monitoring of oil pollution. For State waters Environment Plans under the Petroleum (Submerged Lands) (Environment) Regulations 2012, an oil spill contingency plan (OSCP) is required under regulation 12 (as part of the Environment Plan).

A significant hydrocarbon spill during the petroleum activities associated with the proposed Browse to NWS Project is unlikely but, should such an event occur, it will be managed in accordance with Woodside's overarching emergency response system and supporting documents. Supporting documents include the relevant ERPs, OPEPs, OSCPs and specific plans that provide tactical response guidance to the activity/area.

Monitoring of Environmental Performance

Environmental objectives have been developed for each environmental aspect (**Section 6**). In addition, Environmental Performance Objectives (EPOs) standards and measurement criteria will be developed and monitored as part of the development and subsequent implementation of Environment Plans.

To verify that requirements are met, Woodside and its contractors will monitor compliance during execution of the proposed Browse to NWS Project. The monitoring will be described in detail in the various management plans (**Section 8.14**) and Environment Plans for the specific activities and will make use of tools and systems that are appropriate to the activity and the project teams.

Auditing

During the execution of project activities, environmental performance auditing will be undertaken to:

- identify potential new environmental impacts and risks or changes to existing environmental impacts and risks
- confirm that any controls that are applied to manage impacts and risks to an acceptable level are effective
- confirm compliance with the controls and environmental performance standards detailed in future Environment Plans.

Reporting

Woodside will undertake external reporting at a number of levels. These reporting arrangements are outlined below.

Environmental Performance Reporting

In accordance with applicable environmental legislation, Woodside, as operator for and on behalf of the BJV, is required to report information on environmental performance during the implementation of the proposed Browse to NWS Project including:

- Annual compliance reporting addressing compliance with any conditions of approvals under the EPBC Act and EP Act.
- Monthly Recordable Incident Reports – submitted monthly to NOPSEMA and DMIRS, with details of recordable incidents that have occurred during the previous month (if any).
- Environmental Performance Reports – submitted annually to NOPSEMA and DMIRs and addressing compliance with the EPOs outlined in subsequent Environment Plans developed for activities associated with the proposed Browse to NWS Project.
- Notification of reportable incidents to NOPSEMA or DMIRs according to the requirements of Regulations 26, 26A and 26AA of the Environment Regulations or Regulation 28 of the Petroleum (Submerged Lands) (Environment) Regulations 2012, respectively.

Management of Change

Management of changes to activity scope that are relevant to this draft EIS/ERD (**Chapter 3**) will be in accordance with Regulation 17 of the Environment Regulations. These changes may include:

- review of advances in technology at stages where new equipment may be selected
- changes in understanding of the environment, including all current advice on species protected under the EPBC Act
- current requirements for AMPs (**Chapter 5**)
- potential new advice from external stakeholders (**Chapter 4**).

Risk will be assessed in accordance with the Environmental Risk Management Methodology (**Chapter 6**) to determine the significance of any potential new environmental impacts or risks not provided for in this draft EIS/ERD or subsequently submitted Environment Plans. Risk assessment outcomes will be reviewed in compliance with Regulation 17 of the Environment Regulations.

CHAPTER 9

OVERALL CONCLUSIONS

9. OVERALL CONCLUSIONS

9.1 Summary

Woodside, on behalf of the BJV, has prepared this draft EIS/ERD for the proposed Browse to NWS Project to meet the requirements of the EPBC Act and EP Act, as set out in the approved EISG/ESD. Significant work has been completed by Woodside and the BJV participants to understand the environmental context of the proposed Browse to NWS Project and develop a proposal for the development of the Browse resources that aligns with the principles of Ecologically Sustainable Development (ESD).

This Chapter provides a qualitative assessment of the cumulative impacts by receptor, based on the detailed aspect-based impact and risk assessment provided in **Chapter 6**. It also provides an overall conclusion as to the environmental acceptability of the proposed Browse to NWS Project and includes discussion on alignment with the principles of ESD and the objectives and requirements of the EPBC Act and EP Act. Consideration has also been made of the potential cumulative environmental impacts of the proposed Browse to NWS Project and any existing and future concurrent activities.

The significance of the potential impacts to key receptor groups associated with each aspect of the proposed Browse to NWS Project are detailed in **Chapter 6**, including the acceptability of predicted impacts and potential risks for each aspect in terms of the defined acceptability criteria. In addition, **Chapter 7** specifically addresses GHG emissions, including estimated contributions to global emissions.

9.2 Overall Assessment of Impacts on Receptors (Cumulative Impacts)

9.2.1 Aspect-based cumulative impacts

An aspect-based cumulative impact assessment (i.e. assessment of cumulative impacts from the same aspect resulting from multiple project activities and other developments in the area) is presented for each aspect in **Chapter 6**. This assessment has shown that aspect-based cumulative impacts resulting from the proposed Browse to NWS Project are unlikely to result in significant impacts. The majority of emissions and discharges will be within the Browse Development Area, which is in a remote, offshore location and unlikely to result in significant interactions with other activities/ developments.

9.2.2 Receptor based cumulative impacts

Table 6-2 outlines all the aspect-receptor relationships identified during the assessment of impacts and risks associated with the proposed Browse to NWS Project. Each of these relationships are discussed in **Chapter 6** and **Table 6-2** also highlights where multiple aspects may impact common receptors (i.e. receptor-based cumulative impacts). The cumulative impact assessment focuses on predicted impacts from planned routine and non-routine activities and evaluates the nature of any aspect interaction (e.g. whether one aspect exacerbates the impact of another) and the scale of the cumulative impact as a result. This assessment has not been completed for risks, as the likelihood of the events coinciding is low. An overall assessment of the environmental risks from unplanned events and incidents is presented in **Section 9.3**.

Regional facility/activity context

The Prelude, Ichthys and Crux facilities are located >100 km to the north east of the Browse Development Area and the south western end of the BTL is located in close proximity to the North Rankin Complex (NRC).

Shipping activity in and around the Browse Development Area is sparse, with the main commercial shipping routes located approximately 50 to 100 km west of the Development Area, intersecting the proposed BTL route at various locations depending on the port. Future seismic survey activities may be undertaken by Woodside and/or other operators in the region.

9.2.2.1 Physical Receptors

Marine sediment quality (medium value (open waters))

Table 9-1 Marine sediment quality cumulative assessment

<table>
<tr><th>Receptor</th><th colspan="3">Sediment Quality</th></tr>
<tr><td>Local environment context</td><td colspan="3">Sediments in the Project Area are typical of an undisturbed tropical offshore environment, with low concentrations of metals and nutrients and no hydrocarbons detected from marine sediment quality seabed sampling (refer to Section 5.2.10).</td></tr>
<tr><td>Receptor sensitivity</td><td colspan="3">Medium value (open waters)
Ambient sediment quality is typical of the surrounding environment, with low sensitivity to change and no features of conservation value</td></tr>
<tr><td>Environmental objective</td><td colspan="3">Objective 1: To not result in a substantial change in sediment quality which may adversely impact on biodiversity, ecological integrity, social amenity or human health.
Objective 2: To not result in persistent organic chemicals, heavy metals, or other potentially harmful chemicals accumulating in the marine environment such that biodiversity, ecological integrity, social amenity or human health may be adversely affected.</td></tr>
<tr><td rowspan="6">Relevant aspects: Proposed Browse to NWS Project</td><td><i>Aspect</i></td><td><i>Magnitude</i></td><td><i>Impact significance level</i></td></tr>
<tr><td>Physical Presence: Seabed disturbance</td><td>No lasting effect</td><td>Negligible (F)</td></tr>
<tr><td>Marine Discharges: Produced water</td><td>No lasting effect</td><td>Negligible (F)</td></tr>
<tr><td>Marine Discharges: Drilling discharges</td><td>Minor</td><td>Minor (D)</td></tr>
<tr><td>Marine Discharges: Subsea control fluids</td><td>Slight</td><td>Slight (E)</td></tr>
<tr><td>Marine Discharges: Hydrotest Fluid</td><td>No lasting effect</td><td>Negligible (F)</td></tr>
<tr><td colspan="4"><i>Aspect Interaction Assessment and Conclusion</i></td></tr>
<tr><td colspan="4">Given the isolated FPSO locations, cumulative impacts on sediment resulting from interactions with other facilities and regional vessel/air traffic are not considered credible.
As described throughout Chapter 6, discharges from construction activities and during operations will be managed to ensure no change to sediment quality within the Scott Reef shallow water benthic habitats (<75 m water depth), therefore impacts to sediment will be confined to deep water.
Impacts to sediment from the Browse to NWS Project are expected to primarily result from drilling discharges (e.g. cementing, cuttings/fluids). There is potential for overlap of impact from drilling discharges and subsea control fluids in the immediate vicinity around the wells. Control fluid impacts will occur in the area previously impacted by drilling discharges. Impacts associated with hydrotest discharges may overlap with impacts from prior drilling discharges where the discharge point is in the vicinity of a drill centre, however, they will be short lived and localised. There is also potential for interaction between BTL hydrotest discharges at NRC and existing discharges (e.g. PW) from that facility. These impact interactions are not expected to exacerbate the aspect-based impacts previously described in Chapter 6, due to their localised scale and temporary nature (e.g. hydrotest discharges), dynamic receiving environment and general lack of reactivity between the discharges.
The overall impact significance level of impacts on sediment quality has been assessed as Minor (D) (based on the assessment of impacts resulting from drilling discharges). As per the criteria outlined in Section 6.2.3.4, it is considered that the environmental objectives for this receptor will be achieved and this impact is assessed as Acceptable.</td></tr>
</table>

Water quality (medium value (open waters))

Table 9-2 Water quality cumulative assessment

Receptor	Water Quality		
Local environment context	Water quality in the Project Area near the location of the proposed subsea infrastructure and facilities is typical of an undisturbed tropical offshore environment. Much of the surface waters in this area is nutrient-poor, influenced by the Indonesian Throughflow, with low levels of primary productivity (Section 5.2.9).		
Receptor sensitivity	**Medium value (open water)** Ambient water quality is typical of an open water environment, with low sensitivity to change.		
Environmental objective	**Objective 3:** To not result in a substantial change in water quality which may adversely impact on biodiversity, ecological integrity, social amenity or human health.[1]

Receptor	**Water Quality**
Aspect Interaction Assessment and Conclusion	
Given the isolated FPSO locations, cumulative impacts on water quality resulting from interactions with other facilities and regional vessel/air traffic are not considered credible. There is potential for interaction between the BTL hydrotest discharge at NRC and existing discharges (e.g. PW) from that facility, however, this is likely to be of a short duration (**Section 6**) and the peak concentrations will be physically separated as the BTL will be discharged near seabed and the NRC PW plume is positively buoyant. Impacts to water quality are predicted to primarily arise from the discharge of PW (**Section 6.3.12**) and cooling water (**Section 6.3.13**) from the FPSO facilities during the operations phase, as these discharges are persistent for the field life. Less significant impacts are predicted as a result of short-term or temporary discharges (i.e. discharge of drill cuttings and fluids during development drilling, subsea control fluids, hydrotest fluids, treated sewage and sullage, treated utility water and putrescible waste). As described in **Chapter 6**, operational discharges (PW and cooling water from the FPSO facilities) will be managed to meet the defined threshold values (i.e. 99% species protection or no effect concentrations) at the edge of the mixing zone and at the State waters 3 nm boundary 95% of the time, based on dispersion modelling results. As such, no impacts from operational discharges to water quality within the Scott Reef shallow water benthic habitat (<75m) are predicted. It is recognised that plumes from operational discharges (PW, cooling water and sewage and sullage) occur simultaneously from the same facility. This has the potential to result in chemical interactions between the constituents of the discharges. However, given the reactive and volatile nature of constituents as well as the low concentrations of constituents in the discharges (ie chlorine <1ppm), it is considered that the constituents of a single discharge will react faster with the marine environment than they will with other plumes. For example, dosing of cooling water with chlorine (as sodium hypochlorite) may give rise to chlorine-produced oxidants comprising weak hypochlorous acid, hypochlorite ions and hypobromous acid, depending on the conditions of the marine environment. The decay of these chlorine-produced oxidants is already rapid in the marine environment (DHI 2011a), and therefore unlikely to react with other discharges. This is particularly true as the plumes caused by the discharges dilute rapidly in the marine environment, and are unlikely to immediately come into contact with other plumes before they are diluted. It is therefore highly likely that any undesirable molecular compounds generated from temporary plume co-occurrence and chemical reactions will be below detectable/background thresholds, particularly towards sensitive receptors ie Scott Reef. As per the management approach for Produced Water, baseline and periodic monitoring in the receiving environment will be undertaken to detect changes to water and sediment quality as a result of FPSO facility PW discharge. The effect of these changes in water quality is not expected to be cumulative in the context of the broader region, given the assimilative capacity of the open ocean receiving environment, physical separation of discharge point and the localised scale of the impacts. As such, the overall impact significance level of impacts on water quality has been assessed as Minor (D) (based on the assessment of impacts resulting from PW and cooling water discharges from the FPSO facilities). As per the criteria outlined in **Section 6.2.3.4**, it is considered that the environmental objective for this receptor will be achieved and this impact is assessed as **Acceptable**.	

Air quality (medium value (open waters))

<tr><td colspan="4">Given the isolated FPSO locations, cumulative impacts on ambient noise resulting from interactions with other facilities and regional shipping activities are not considered credible. There may, on occasion, be overlap between facility operational noise and regional seismic surveys completed by Woodside and/or other operators. This interaction would be managed in Environment Plans required under Petroleum Legislation.
Atmospheric (Section 6.3.7) and underwater (Section 6.3.8) noise emissions are predicted to occur during all phases of the proposed Browse to NWS Project. Impacts of these noise emissions on ambient atmospheric noise levels are, however, expected to be Negligible (F). Impacts from underwater noise are expected to be Slight (E). Sensitive receptors to underwater noise are generally different to the receptors for atmospheric noise, and primary sources of atmospheric noise at the Browse Development Area (helicopters, piling, flaring) will be intermittent, no significant cumulative impact to ambient atmospheric noise levels is predicted.
As such, the overall impact significance level of impacts on ambient noise has been assessed as Slight (E). As per the criteria outlined in Section 6.2.3.4, it is considered that the environmental objective for this receptor will be achieved and this impact is assessed as Acceptable.</td></tr>
</table>

9.2.2.2 Ecological Receptors

Plankton communities (medium value (open waters))

Table 9-6: Plankton communities cumulative assessment

Receptor	Plankton Communities		
Local environment context	Plankton communities have a naturally variable distribution in both space and time, noting that the NWMR is typically characterised by low planktonic productivity. Estimates of the phytoplankton biomass (measured as chlorophyll a) close to Scott Reef are approximately twice that of open waters (sampled at distances greater than 50 km to the south-west of South Scott Reef). The open water location sampled is likely to be representative of the general outer shelf open water environment and so is representative of the oceanic waters of the Project Area (Section 5.3.1.1).		
Receptor sensitivity	**Medium value (open water)** Plankton populations are typical of an open water environment, with low sensitivity to change due to high turnover/recovery and no species of high importance or quality.		
Environmental objective	**Objective 7:** To not have a substantial adverse effect on a population of plankton, including its lifecycle and spatial distribution.		
Relevant aspects: Proposed Browse to NWS Project	***Aspect***	***Magnitude***	***Impact significance level***
	Physical Presence: Seabed Disturbance	No lasting effect	Negligible (F)
	Physical Presence: Light	No lasting effect	Negligible (F)
	Underwater Noise Emissions	No lasting effect	Negligible (F)
	Marine Discharges: Sewage and Sullage	No lasting effect	Negligible (F)
	Marine Discharges: Treated Utility Water, Chemical and Deck Drainage	No lasting effect	Negligible (F)

	Marine Discharges: Subsea control fluids	No lasting effect	Negligible (F)
	Marine Discharges: Hydrotest Fluid	No lasting effect	Negligible (F)

Receptor	Plankton Communities
Aspect Interaction Assessment and Conclusion	
Given the isolated FPSO locations, cumulative impacts on plankton resulting from interactions with other facilities and regional vessel/air traffic are not considered credible. Slight impacts to plankton communities may result from multiple but separated discharge streams, including PW (Section 6.3.12) and cooling water (Section 6.3.13) discharges from the FPSO facilities during operations. Less significant impacts, expected to have no lasting effect on plankton populations, may occur during construction, commissioning and operations as a result of discharges including hydrotest fluid, vessel cooling water, treated utility water and putrescible waste; as well underwater noise emissions. As described above, no significant increase in toxicity is predicted as a result of potential comingling of the PW and cooling water plumes after discharge. Furthermore, plankton populations are widespread and have a high turnover. The predicted cumulative impacts resulting from the multiple discharge streams are not expected to be significant. As such, the overall impact significance level of impacts on plankton has been assessed as Slight (E) (based on the assessment of impacts resulting from PW and cooling water discharges from the FPSO facilities). As per the criteria outlined in Section 6.2.3.4, it is considered that the environmental objective for this receptor will be achieved and this impact is assessed as **Acceptable**.	

Shallow water benthic communities and habitats (<75 m water depth) (high value habitat)
As detailed in Chapter 6, no infrastructure is planned to be placed on or near any shallow water benthic habitats (e.g. Scott Reef and the Rowley Shoals). In addition, discharges during construction, commissioning and operations will be managed to avoid impact to these shallow water benthic habitats. This will include a commitment to manage operational discharges (PW and cooling water from the FPSO facilities) to meet the defined threshold values (i.e. 99% species protection or lowest no effect concentration) at the edge of the mixing zone and at the State waters 3 nm boundary, 95% of the time; and a commitment to manage drilling discharges (in particular bottom hole discharges) at drill centre locations in the State Proposal Area (i.e. TRA, TRD, TRE and TRF) in such a manner to avoid impacts to Scott Reef shallow water benthic communities and habitats (<75 m water depth). These management objectives are supported by a range of both feasible and industry proven management measures. As such, no cumulative impact assessment is warranted for this receptor.

Deepwater benthic communities and habitats (>75 m water depth) (medium value habitat)

Table 9-7: Deepwater benthic communities and habitats cumulative assessment

Receptor	Deepwater benthic communities and habitats
Local environment context	The benthic communities inhabiting the predominantly soft, fine sediments of the deepwater benthic habitats are characterised by infauna such as polychaetes and sparsely distributed sessile and mobile epifauna. The density of benthic fauna is typically lower in deep-sea sediments (greater than 200 m) than in shallower coastal sediment habitats, but the diversity of communities may be similar. As confirmed by deepwater surveys (Section 5.3.1.2).
Receptor sensitivity	**Medium value** No species of high importance.
Environmental objective	**Objective 6:** To not modify, destroy, fragment, isolate or disturb an important or substantial area of habitat such that an adverse impact on marine ecosystem functioning or integrity results.

Receptor	**Deepwater benthic communities and habitats**		
Relevant aspects: Proposed Browse to NWS Project	***Aspect***	***Magnitude***	***Impact significance level***
	Physical Presence: Seabed Disturbance	Minor	Minor (D)
	Underwater Noise Emissions	No lasting effect	Negligible (F)
	Marine Discharges: Sewage and Sullage	No impact expected	
	Marine Discharges: Treated Utility Water, Chemical and Deck Drainage	No impact expected	
	Marine Discharges: Putrescible Waste	No impact expected	
	Marine Discharges: Produced water	No impact expected	
	Marine Discharges: Cooling Water	No impact expected	
	Marine Discharges: Drilling Discharges	Slight	Slight (E)
	Marine Discharges: Subsea control fluids	No lasting effect	Negligible (F)
	Marine Discharges: Hydrotest Fluid	No lasting effect	Negligible (F)

Aspect Interaction Assessment and Conclusion

Cumulative impact from oil and gas infrastructure within the Browse Development Area and broader Browse Basin effects a relatively small proportion of deepwater benthic habitat and community types present in these areas. The habitat types affected are typically of low sensitivity (relatively benign, see above) as infrastructure typically avoids areas of complex bathymetry and inferred higher habitat sensitivity. Minor impacts to the deepwater benthic habitats and communities are predicted within the Project Area as a result of the localised physical footprint of the installed subsea infrastructure, BTL and inter-field spur line (including seabed preparation and installation activities) (**Section 6.3.1**). In addition, discharges during construction, commissioning and operations (including the drilling discharges, subsea control fluids and hydrotest fluids) may impact these deepwater benthic habitats and communities.

Combined impacts to deepwater benthic habitats and communities within the Project Area as a result of the installation of the subsea infrastructure and drilling discharges (**Section 6.3.15**) are not expected to be significant as they will be restricted to areas largely composed of sediment habitat and sparse benthic biota and the physical footprint represents a small fraction of the widespread and representative deepwater benthic habitat type within the region. Further, there are no predicted lasting impacts to these deepwater benthic habitats from other discharges related to the proposed Browse to NWS Project.

As such, the overall impact significance level of impacts on deepwater benthic habitats has been assessed as Minor (D) (based on the assessment of impacts resulting from seabed disturbance (Minor (D)) and drilling discharges (Slight (S)). As per the criteria outlined in **Section 6.2.3.4**, it is considered that the environmental objective for this receptor will be achieved and this impact is assessed as **Acceptable**.

Fauna (high value species)

Seabirds and migratory shorebirds

Table 9-8: Seabirds and migratory shorebirds cumulative assessment

<table>
<tr><th>Receptor</th><th colspan="3">Seabirds and migratory shorebirds</th></tr>
<tr><td>Local environment context</td><td colspan="3">As the only emergent land mass within the immediate vicinity of the Browse Development Area, Scott Reef serves to provide nesting and/or roosting for seabirds, albeit in small numbers in comparison to other breeding and roosting sites in the region. This includes the little tern, which has a resting BIA at Scott Reef, associated with Sandy Islet. In addition, due to the large geographical range of seabirds, most species occurring within the wider NWMR have the potential to occur and transit through the Project Area.
The islands of the Rowley Shoals (which the BTL route passes by at a distance of a few kilometres) are known to support a wide range of seabird species, including WA's second largest breeding colony of red-tailed tropicbird. The Rowley Shoals have also been identified as BIAs for the white-tailed tropicbird.
Migratory shorebirds are occasionally observed in very low numbers at Scott Reef and Sandy Islet may be used as a staging ground during the migration between the Northern Hemisphere and Australia. However, given its small size, Sandy Islet is unlikely to support large numbers of migratory shorebirds. Due to the large geographical ranges of migratory shorebirds, many of the species known to occur within the wider NWMR have the potential to transit through the Project Area, which overlaps with the migratory shorebird corridor. Shorebird presence in the Project Area is expected to be transitory and seasonal (Section 5.3.2.3).</td></tr>
<tr><td>Receptor sensitivity</td><td colspan="3">High value species

</table>

Receptor	Seabirds and migratory shorebirds
Aspect Interaction Assessment and Conclusion	
Given the isolated FPSO locations, cumulative impacts on seabirds and migratory shorebirds resulting from interactions with other facilities and regional vessel/air traffic are not considered significant. As nesting and feeding aggregation areas are generally in coastal locations, the greatest potential for cumulative industrial impacts in the region is due to increased prevalence of light sources that may interrupt migratory behaviour. Given the extremely low density of oil and gas infrastructure, cumulative impact at a population level is considered unlikely. Some slight behavioural impact on seabirds and migratory shorebirds may occur as a result of atmospheric noise from helicopters and flaring and light emissions from vessels, MODUs and the FPSO facilities. However, the slight magnitude of these light impacts and the infrequent nature of the atmospheric noise emissions means that no increase to the significance of the predicted impacts due to exposure to multiple aspects is predicted. As such, the overall impact significance level of impacts on seabirds and migratory shorebirds has been assessed as Minor (D) (based on the assessment of impacts resulting from light emissions (Minor (D)) and atmospheric noise (Slight (S)). As per the criteria outlined in Section 6.2.3.4, it is considered that the environmental objectives for this receptor will be achieved and this impact is assessed as **Acceptable**.	

Fish

Table 9-9: Fish cumulative assessment

Receptor	Fish
Local environment context	Fish assemblages within the Browse Development Area occupy a diverse range of habitats and are typical of the fish communities and species representative of the Timor Province. These fish assemblages include : + shallow-water, site-attached coral reef fish communities with characteristically high diversity and abundance + open water pelagic fish + deepwater, demersal fish communities (**Section 5.3.2.8**). EPBC Act listed fish species that may occur within the Project Area include the whale shark, shortfin mako, longfin mako, green sawfish and largetooth sawfish. The whale shark foraging BIA extends north along the northern WA coastline (predominately inshore of the Project Area) from Ningaloo almost to the Northern Territory (NT) border (Section 5.3.2.2). Based on studies undertaken of the whale shark's migratory behaviours, this species may occur within the Project Area, albeit in low numbers (Section 5.3.2.7).
Receptor sensitivity	**High value species** MNES species known to be present.
Environmental objective	**Objective 12**: To not substantially modify, destroy or isolate an area of important habitat for a threatened or migratory species. **Objective 13**: To not seriously disrupt the lifecycle (breeding, feeding, migration or resting behaviour) of an ecologically significant proportion of the population of a threatened or migratory species. **Objective 14**: To not have a substantial adverse effect on a population of fish, or the spatial distribution of the population.

Receptor	**Fish**		
Relevant aspects: Proposed Browse to NWS Project	***Aspect***	***Magnitude***	***Impact significance level***
	Physical Presence: Light	No lasting effect	Slight (E)
	Physical Presence: Electromagnetic Emissions	No lasting effect	Slight (E)
	Atmospheric Noise Emissions	No lasting effect	Slight (E)
	Underwater Noise Emissions	No lasting effect	Slight (E)
	Marine Discharges: Sewage and Sullage	No lasting effect	Slight (E)
	Marine Discharges: Treated Utility Water, Chemical and Deck Drainage	No lasting effect	Slight (E)
	Marine Discharges: Putrescible Waste	No lasting effect	Slight (E)
	Marine Discharges: Produced water	No lasting effect	Slight (E)
	Marine Discharges: Cooling Water	No lasting effect	Slight (E)
	Marine Discharges: Drilling Discharges	No lasting effect	Negligible (F)
	Marine Discharges: Subsea control fluids	No lasting effect	Slight (E)
	Marine Discharges: Hydrotest Fluid	No lasting effect	Slight (E)

Aspect Interaction Assessment and Conclusion

Given the isolated FPSO locations, cumulative impacts on fish resulting from interactions with other facilities and regional vessel/air traffic are not considered credible. Mitigation measures detailed in **Chapter 6** for whale sharks will ensure no impact on migration patterns. Slight impacts with no lasting effect may occur to fish as a result of discharges during construction, commissioning and operations, including hydrotest fluid, cooling water, PW, treated utility water, sewage and sullage and putrescible waste. Slight impacts with no lasting effect may also occur as a result of underwater noise emissions during construction (e.g. piling, VSP, MODU on DP) and operations (e.g. subsea infrastructure operations, routine FPSO operations, use of DP). Given the nature of these discharges and emissions (location and frequency) it is possible that any fish may be exposed to multiple aspects concurrently (e.g. concurrent exposure to underwater noise emissions and marine discharges from the FPSO facilities such as PW and cooling water). However, given no lasting effect on fish are expected to occur from these aspects, no significant cumulative impacts are predicted.

As such, the overall impact significance level of impacts on fish has been assessed as Slight (E). As per the criteria outlined in **Section 6.2.3.4**, it is considered that the environmental objectives for this receptor will be achieved and this impact is assessed as **Acceptable**.

Marine mammals

Table 9-10: Marine mammals cumulative assessment

Receptor	Marine mammals
Local environment context	The PMST identified 27 marine mammal species as potentially occurring within the Project Area. Of these, the pygmy blue whale (endangered and migratory), humpback whale, sei whale, fin whale (vulnerable and migratory) and Bryde's whale (migratory) are considered most likely to occur (albeit representing a low percentage of each species populations) within the Project Area and/or interact with the proposed Browse to NWS Project (**Section 5.3.2.4**). There are BIAs for migration and breeding and calving for the humpback whale along the WA coast and within the NWMR, but there are no known BIAs within the Project Area. A migratory BIA for the pygmy blue whale extends for most of the length of the NWMR within offshore waters and encompasses Scott Reef. The Conservation Plan for Blue Whales (Commonwealth of Australia, 2015) also documents a possible foraging area which encompasses the majority of Scott Reef and its surrounds. It is expected pygmy blue whales may occur within the Browse Development Area, albeit in low numbers, and it is acknowledged that pygmy blue whales have been recorded in the channel between North and South Scott Reef; and that they may forage opportunistically in and around Scott Reef (given it is a possible foraging BIA). Other marine mammal species identified as likely to occur in the Project Area (such as the sei whale, fin whale and Bryde's whales) are expected to be limited to infrequent transient individuals (**Section 5.3.2.4.3**).
Receptor sensitivity	**High value species** MNES species known to be present.
Environmental objective	**Objective 12**: To not substantially modify, destroy or isolate an area of important habitat for a threatened or migratory species. **Objective 13**: To not seriously disrupt the lifecycle (breeding, feeding, migration or resting behaviour) of an ecologically significant proportion of the population of a threatened or migratory species. **Objective 15**: To not have a substantial adverse effect on a population of marine mammals, or the spatial distribution of the population.

Receptor	**Marine mammals**		
Relevant aspects: Proposed Browse to NWS Project	***Aspect***	***Magnitude***	***Impact significance level***
	Physical Presence: Electromagnetic Emissions	No lasting effect	Slight (E)
	Atmospheric Noise Emissions	No lasting effect	Slight (E)
	Underwater Noise Emissions	Slight	Minor (D)
	Marine Discharges: Sewage and Sullage	No lasting effect	Slight (E)
	Marine Discharges: Treated Utility Water, Chemical and Deck Drainage	No lasting effect	Slight (E)
	Marine Discharges: Produced water	No lasting effect	Slight (E)

	Marine Discharges: Subsea control fluids	No lasting effect	Slight (E)
	Marine Discharges: Hydrotest Fluid	No lasting effect	Slight (E)

Aspect Interaction Assessment and Conclusion

Given the isolated FPSO locations, cumulative impacts on marine mammals resulting from interactions with other facilities and regional vessel/air traffic are considered minor. Regional oil and gas infrastructure is located in the migratory pathways, but not in known aggregation areas for key marine mammal species such as Pygmy Blue Whales and Humpback Whales. Both species have shown recovery since the cessation of whaling despite increased oil and gas (and general shipping) activities on the North West Shelf (**Chapter 5**). The primary source of potential impacts to marine mammals such as pygmy blue whales is from underwater noise emissions during construction (e.g. piling, VSP, MODU on DP) and operations (e.g. subsea infrastructure operations, routine FPSO operations, use of DP) (**Section 6.3.8**). No lasting effect on marine mammals is predicted as a result of other aspects, including marine discharges.

As described in **Section 6.3.8**, modelling has indicated that while no injury or mortality to marine mammals is predicted to occur, there is potential for some degree of behavioural disturbance as a result of underwater noise emissions associated with the proposed Browse to NWS Project. These impacts are expected to be localised behavioural disturbance of marine mammals within the vicinity of the noise source. Modelling of a representative cumulative scenario indicated that this behavioural response would be limited to less than 2% of the area identified as a possible foraging area for pygmy blue whales, leaving 98% available for uninterrupted foraging.

Given no other aspect is predicted to have any lasting effect on marine mammals and cumulative impact from multiple aspects is not expected to be significant.

As such, the overall impact significance level of impacts on marine mammals has been assessed as Minor (D) (based on the assessment of impacts resulting from underwater noise emissions). As per the criteria outlined in **Section 6.2.3.4**, it is considered that the environmental objectives for this receptor will be achieved and this impact is assessed as **Acceptable**.

Marine reptiles

</table>

Receptor	Marine reptiles
Aspect Interaction Assessment and Conclusion	
Given the isolated FPSO locations, cumulative impacts on marine reptiles resulting from interactions with other facilities and regional vessel/air traffic are considered minor. The greatest potential for cumulative impact to marine reptiles in the region is considered to result from light pollution on nesting areas. The primary sources of potential impacts to marine turtles are artificial light emissions from the MODU and FPSO facilities operating at Torosa; and underwater noise emissions resulting from potential pile driving activities, drilling and the MODU DP. Chemical discharges are noted as a threat to marine turtles in the Recovery Plan for Marine Turtles in Australia 2017-2027' (Commonwealth of Australia, 2017), however, marine discharges from the proposed Browse to NWS Project are not predicted to result in any last lasting affect on marine turtles. As described in **Chapter 6**, impacts from these aspects on marine turtles are not predicted to be significant and it is considered that they can be managed to an acceptable level through the implementation of mitigation measures. Cumulative impacts may occur as a result of simultaneous exposure to these aspects. For example, nesting turtles or hatchling attracted by light emissions from the Torosa FPSO facility or a MODU operating at Torosa would subsequently be exposed to noise emissions and marine discharges from the FPSO or MODU (e.g. DP noise). These cumulative impacts would be limited to behavioural responses in a small number of adult marine turtles and are not expected to be significant. Cumulative impacts to marine turtles may also occur as a result of attraction resulting from light emissions and concurrent exposure to other temporary, higher intensity noise emissions such as pile driving and VSP noise emissions. However, with the implementation of a proposed 500 m shut down zone during pile driving and VSP operations, as well as pre-start up visual observations, soft starts, operational and shutdown procedures; significant cumulative impacts resulting from light and noise emission from pilling and VSP operations are not expected to occur. Cumulative impacts could also occur as a result of non-simultaneous exposure to light and noise emissions. For example, decreased nesting success as a result of behavioural impacts from noise emissions (i.e. females avoiding nesting habitat at Sandy Islet) combined with decreased hatchling survival rates due to disorientation from light emissions would have a combined impact on the overall population success of green turtles. However, as described in **Chapter 6**, light and noise emissions are not expected to significantly impact the breeding cycle of marine turtles at Sandy Islet, Scott Reef (predominately green turtles) and given the temporary nature of pile driving activities and the MODU's presence at a single location, no significant cumulative impacts on the nesting success or hatchling survival rates are expected as a result of the proposed Browse to NWS Project. Potential impacts may also occur to sea snakes as a result of marine discharges and underwater noise emissions resulting from the proposed Browse to NWS Project. As described in **Chapter 6**, impacts to water quality are not expected to be significant and impacts to sea snakes from noise emissions are expected to be limited to slight behavioural/avoidance impacts. No significant cumulative impacts to sea snakes within the Project Area are predicted. As such, the overall impact significance level of impacts on marine reptiles has been assessed as Minor (D) based on the assessment of impacts resulting from underwater noise emissions (Minor (D)) and light emissions (Minor (D)). As per the criteria outlined in **Section 6.2.3.4**, it is considered that the environmental objective for this receptor will be achieved and this impact is assessed as **Acceptable**.	

Key Ecological Features (KEF) (medium value)

Table 9-12: KEF Features cumulative assessment

Receptor	KEF Features		
Local environment context	The Browse Development Area overlaps with the Continental slope demersal fish communities and Seringapatam Reef and Commonwealth waters in the Scott Reef Complex KEFs. The proposed BTL route traverses the Mermaid Reef and Commonwealth waters surrounding Rowley Shoals KEF and the Ancient coastline at 125 m depth contour KEF (**Section 5.3.3.1**).		
Receptor sensitivity	**Medium value** Designated sensitive Area. Values protected by legislation.		
Environmental objective	**Objective 17**: To not modify, destroy, fragment, isolate or disturb an important or substantial area of habitat such that an adverse impact on marine ecosystem functioning or integrity in an area defined as a Key Ecological Feature.		
Relevant aspects: Proposed Browse to NWS Project	***Aspect***	***Magnitude***	***Impact significance level***
	Physical Presence: Seabed Disturbance	No lasting effect	Negligible (F)
	Underwater noise	No lasting effect	Negligible (F)
	Marine Discharges: Sewage and Sullage	No lasting effect	Negligible (F)
	Marine Discharges: Treated Utility Water, Chemical and Deck Drainage	No lasting effect	Negligible (F)
	Marine Discharges: Putrescible Waste	No lasting effect	Negligible (F)
	Marine Discharges: Produced water	No lasting effect	Negligible (F)
	Marine Discharges: Cooling Water	No lasting effect	Negligible (F)
	Marine Discharges: Drilling Discharges	No lasting effect	Negligible (F)
	Marine Discharges: Subsea control fluids	No lasting effect	Negligible (F)
	Marine Discharges: Hydrotest Fluid	No lasting effect	Negligible (F)

Receptor	**KEF Features**
Aspect Interaction Assessment and Conclusion	
Seabed disturbance and marine discharges will occur within these KEFs, however, no lasting effect is predicted to occur to the conservation values of these KEFs. The Project will be the first permanent infrastructure installed in the following KEFs: + Seringapatam Reef and Reef and Commonwealth waters in the Scott Reef Complex KEF + Mermaid Reef and Commonwealth waters surrounding Rowley Shoals KEF Existing anthropogenic impacts for these KEFs include climate change related impacts, physical habitat modification (shipping anchorage, offshore construction and fishing practices (Commonwealth of Australia, 2012). The Project is likely to represent the largest (yet negligible) impact in terms of physical habitat modification in these KEFs therefore the impact described in **Chapter 6** is considered an accurate depiction of cumulative impact. The Continental Slope Demersal Fish Communities and Ancient Coastline at 125 m depth contour KEFs contain other existing oil and gas infrastructure (pipelines and the North Rankin Complex). Given the small Project footprint relative to the total KEF area, and narrow footprint of pipeline infrastructure (allowing connectivity to be retained), the cumulative increase is not considered significant. The values of the Continental slope demersal fish communities KEF, the Mermaid Reef and Commonwealth waters surrounding Rowley Shoals KEF and the Seringapatam Reef and Commonwealth waters in the Scott Reef Complex KEF are primarily related to high productivity and aggregations of marine life. As described earlier, no significant cumulative impacts to plankton or fish are expected to occur from concurrent exposure to localised reduced water quality (resulting from marine discharges) and underwater noise emissions. As such, no cumulative impacts to the values of these KEFS (high productivity and aggregations of marine life) are expected. Likewise, seabed disturbance is unlikely to significantly impact productivity or marine life aggregation, and is not expected to contribute to any cumulative impacts to the values of the KEFs. Similarly, impacts to the Ancient coastline at 125 m depth contour KEF may occur where the proposed BTL crosses this KEF near the NRC tie-in point, as a result of the permanent installation of the BTL and temporarily due to vessel-based marine discharges during construction and IMR activities. The values of the Ancient coastline at 125 m depth contour KEF relate primarily to its unique seafloor geology, which are unlikely to be impacted by marine discharges associated with the proposed Browse to NWS Project. As such, no cumulative impacts to this KEF are predicted. As such, the overall impact significance level of impacts on KEFs has been assessed as Negligible (F). As per the criteria outlined in **Section 6.2.3.4**, it is considered that the environmental objective for this receptor will be achieved and this impact is assessed as **Acceptable**.	

Australian Marine Parks (medium value (multiple use zones))

Table 9-13: AMP Features cumulative assessment

<table>
<tr><th>Receptor</th><th colspan="3">AMP Features</th></tr>
<tr><td>Local environment context</td><td colspan="3">The proposed BTL route traverses the Multiple Use Zones (IV) of the ArgoRowley Terrace and Kimberley Marine Parks. It should also be noted that the proposed BTL route passes approximately 2 km from the boundary of the Mermaid Reef Marine Park National Park Zone. Rationale for the route selection of the BTL is provided in Chapter 3.</td></tr>
<tr><td>Receptor sensitivity</td><td colspan="3">Medium value (multiple use zones)
Designated sensitive area. Values protected by legislation.</td></tr>

<tr><td rowspan="8">Relevant aspects: Proposed Browse to NWS Project</td><td><i>Aspect</i></td><td><i>Magnitude</i></td><td><i>Impact significance level</i></td></tr>
<tr><td>Physical Presence: Seabed Disturbance</td><td>No lasting effect</td><td>Negligible (F)</td></tr>
<tr><td>Underwater noise</td><td>No lasting effect</td><td>Negligible (F)</td></tr>
<tr><td>Physical Presence: Light</td><td>No lasting effect</td><td>Negligible (F)</td></tr>
<tr><td>Marine Discharges: Sewage and Sullage</td><td>No lasting effect</td><td>Negligible (F)</td></tr>
<tr><td>Marine Discharges: Treated Utility Water, Chemical and Deck Drainage</td><td>No lasting effect</td><td>Negligible (F)</td></tr>
<tr><td>Marine Discharges: Putrescible Waste</td><td>No lasting effect</td><td>Negligible (F)</td></tr>
<tr><td>Marine Discharges: Cooling Water</td><td>No lasting effect</td><td>Negligible (F)</td></tr>
<tr><td colspan="4"><i>Aspect Interaction Assessment and Conclusion</i></td></tr>
<tr><td colspan="4">Impacts to AMPs may occur as a result of the permanent installation of the proposed BTL and temporarily due to vessel-based marine discharges of cooling water, putrescible waste and sewage and sullage during construction and IMR activities. Threatening processes for the Kimberley Marine Park and Argo-Rowley Terrace Marine Park are similar to those described above for the affected KEFs and cumulative impacts are also considered similar.
The impact of seabed disturbance on the Multiple Use Zone of the two AMPs has been minimised, as far as practicable, based on the route selection process (Chapter 3). Impacts have been assessed as negligible as the area traversed by the proposed BTL represents a small proportion of the total area of the AMPs. The activities are considered to be consistent with the objective of the Multiple Use Zone (VI) to provide for ecologically sustainable use and the conservation of ecosystems, habitats and native species.
As described in Chapter 6, given their temporary and transient nature, the impact of the vessel-based marine discharges are not expected to result in any lasting effect on the values of the two AMPs traversed (i.e. the Kimberley Marine Park and Argo-Rowley Terrace Marine Park). No cumulative impacts are expected to occur to AMPs as a result of marine discharges and seabed disturbance related to the installation of the subsea infrastructure.
As such, the overall impact significance level of impacts on AMPs has been assessed as Negligible (F). As per the criteria outlined in Section 6.2.3.4, it is considered that the environmental objective for this receptor will be achieved and this impact is assessed as Acceptable.</td></tr>
</table>

State marine parks and nature reserves (high value)

Table 9-14: State marine parks and nature reserves cumulative assessment

<tr><th colspan="4">Aspect Interaction Assessment and Conclusion</th></tr>
<tr><td colspan="4">Given the distance of the proposed activities from State Marine Parks (the Rowley Shoals Marine Park is located approximately 3 km from the BTL route at its closest point), no impacts to State Marine Parks as a result of the proposed activities are predicted.
Slight impacts are predicted to occur to the Scott Reef Nature Reserve as a result of potential seabed subsidence.
As described above, no significant cumulative impacts are expected to occur to Scott Reef or the fauna that utilise the reef and Sandy Islet. No cumulative impacts to the Scott Reef Nature Reserve are expected.
As such, the overall impact significance level of impacts on State marine parks and nature reserves has been assessed as Minor (D) (based on the assessment of impacts resulting from subsea subsidence). As per the criteria outlined in Section 6.2.3.4, it is considered that the environmental objective for this receptor will be achieved and this impact is assessed as Acceptable.</td></tr>
</table>

Other protected places (high value)

Table 9-15: Other protected places cumulative assessment

Receptor	**Other protected places**		
Local environment context	There are no National Heritage Sites within the Project Area. The closest National Heritage Sites are the Dampier Archipelago (including the Burrup Peninsula) and the Ningaloo Coast (Section 5.4.3.2). There are no World Heritage Sites within the Project Area (Section 5.4.3.3). Commonwealth Heritage Places located within or within the vicinity of the Project Area include Scott Reef and Surrounds – Commonwealth Area, and Mermaid Reef – Rowley Shoals (Section 5.4.3.1).		
Receptor sensitivity	**High value** Designated sensitive area. Values protected by legislation.		
Environmental objective	**Objective 18**: To not modify, destroy, fragment, isolate or disturb an important or substantial area of habitat such that an adverse impact on marine ecosystem functioning or integrity of a Protected Place. **Objective 19**: To not have a substantial adverse impact on heritage values[1]		
Relevant aspects: Proposed Browse to NWS Project	***Aspect***	***Magnitude***	***Impact significance level***
	Physical Presence: Seabed Disturbance	No impacts predicted	
	Physical Presence: Light	No lasting effect	Slight (E)
	Marine Discharges: Sewage and Sullage	No lasting effect	Negligible (F)
	Marine Discharges: Treated Utility Water, Chemical and Deck Drainage	No lasting effect	Slight (E)
	Marine Discharges: Putrescible Waste	No lasting effect	Slight (E)
	Marine Discharges: Produced water	No impact expected	
	Marine Discharges: Cooling water	No impact expected	
	Marine Discharges: Drilling Discharges	No impact expected	
	Marine Discharges: Hydrotest Fluid	No impact expected	
Aspect Interaction Assessment and Conclusion			
As described above, project activities will be managed to avoid impacts occurring to Scott Reef shallow habitats (<75m) or the waters surrounding the reef and no cumulative impacts to the Scott Reef and Surrounds Commonwealth Heritage Place are expected. Likewise, no impacts are predicted to occur to the Mermaid Reef – Rowley Shoals Commonwealth Heritage Place. As per the criteria outlined in Section 6.2.3.4, it is considered that the environmental objective for this receptor will be achieved and this impact is assessed as **Acceptable**.			

9.2.2.3 Socio-Economic Receptors

State and Commonwealth managed fisheries (high value user)

Table 9-16: State and Commonwealth managed fisheries cumulative assessment

Receptor	State and Commonwealth managed fisheries		
Local environment context	State managed commercial fisheries in close proximity to the Project Area include Northern Demersal Scalefish, Mackerel, WA North Coast Shark, Onslow Prawn, Abalone, South West Coast Salmon, Pilbara Fish Trawl, Specimen Shell, Marine Aquarium Fish, West Coast Deep Sea Crustacean and Pearl Oyster Managed Fisheries. The Commonwealth managed fisheries located within the vicinity of the Project Area include the North West Slope Trawl Fishery, the Western Tuna and Billfish Fishery, the Southern Bluefin Tuna Fishery and the Skipjack Tuna Fishery (Western Skipjack Tuna Fishery). In 1974 the Australia-Indonesia Memorandum of Understanding regarding the Operations of Indonesian Traditional Fishermen in Areas of the Australian Fishing Zone and Continental Shelf – 1974 (MoU 74) was signed by the Governments of Australia and Indonesia, allowing allowed Indonesian fishers to continue to fish in designated areas using traditional methods only (**Section 5.4.2.1** and **Section 5.4.2.2**).		
Receptor sensitivity	**High value marine user** Key fishing area, with high importance to stakeholders.		
Environmental objective	**Objective 20**: To not have a substantial adverse effect on the sustainability of commercial fishing. **Objective 21**: To not interfere with other marine users to a greater extent than is described in the draft EIS/ERD.		
Relevant aspects: Proposed Browse to NWS Project	***Aspect***	***Magnitude***	***Impact significance level***
	Physical Presence: Disturbance to Other Users	Slight	Minor (D)
	Physical Presence: Light	No lasting effect	Slight (E)
	Marine Discharges: Sewage and Sullage	No lasting effect	Slight (E)
	Marine Discharges: Treated Utility Water, Chemical and Deck Drainage	No lasting effect	Slight (E)
	Marine Discharges: Putrescible Waste	No lasting effect	Slight (E)
	Marine Discharges: Produced water	No lasting effect	Slight (E)
	Marine Discharges: Cooling water	No lasting effect	Slight (E)
	Marine Discharges: Subsea control fluids	No lasting effect	Slight (E)
	Marine Discharges: Hydrotest Fluid	No lasting effect	Slight (E)

Aspect Interaction Assessment and Conclusion
The cumulative impact of the Project through disturbance to other users in addition to other anthropogenic sources is unlikely to be significant due to relatively small exclusion zones (typically 500 m) and compatibility with certain fishery types, such as line and trap fishing, which may benefit from the creation of artificial habitat. The total seabed area restricted from trawling activities (due to snag risk) in the region as a result of anthropogenic seabed infrastructure is a relatively small proportion of the available fishery managed zones. Where the functions, interests or activities of other users involve marine fauna (e.g. fisheries), any effect to fauna presence or abundance will indirectly impact on the functions, interests or activities of other users. As described above, no lasting effect on fish are expected to occur as a result of the proposed activities, with the impact significance level of impacts on fish assessed as Slight (E). Further, slight impacts (disturbance to other users) are predicted to occur to managed fisheries as a result of the physical presence of infrastructure (exclusion from a very small portion of potential fishing grounds) associated with the proposed Browse to NWS Project. Given no lasting impact to target fish species is predicted, no cumulative impacts to managed fisheries are expected as a result of impacts to target fish species and the exclusion from some fishing grounds as a result of the physical presence of infrastructure. As such, the overall impact significance level of impacts on State and Commonwealth fisheries has been assessed as Minor (D) (based on the assessment of impacts of disturbance to other users from the physical presence of infrastructure). As per the criteria outlined in **Section 6.2.3.4**, it is considered that the environmental objective for this receptor will be achieved and this impact is assessed as **Acceptable**.

Tourism and Recreation/Scientific Studies (high value user)

Table 9-17: Tourism and Recreation/Scientific studies cumulative assessment

Receptor	Tourism and Recreation/ Scientific studies
Local environment context	Recreation and tourism activities in the NWMR occur predominantly in WA State waters adjacent to coastal population centres (e.g. Broome), with a peak in activity during the winter months (dry season) (**Section 5.4.2.6**). Only one to two recreational fishing charter operators run trips to Scott Reef. The location has the potential to provide significant opportunities for pelagic sport fishing; however, given the distance from Broome and closest landfall and associated costs, only a limited number of charter operators are prepared to take recreational fishers out to Scott Reef. Those companies that do visit Scott Reef tend to make the trip only four to five times per year, spending around five days at the reef each time. Fishing is mainly focused on the south, west and north extremities of Scott Reef, generally only going into the South Scott Reef lagoon for snorkelling and for layover at night.
Receptor sensitivity	**High value users** Project area has low to medium level of utilisation by stakeholders.
Environmental objective	**Objective 21**: To not interfere with other marine users to a greater extent than is described in the draft EIS/ERD.

Receptor	**Tourism and Recreation/ Scientific studies**		
Relevant aspects: Proposed Browse to NWS Project	***Aspect***	***Magnitude***	***Impact significance level***
	Physical Presence: Disturbance to Other Users	Slight	Minor (D)
	Physical Presence: Light	No lasting effect	Slight (E)
	Atmospheric noise emissions	No lasting effect	Slight (E)
	Underwater noise emissions	No lasting effect	Slight (E)
	Marine Discharges: Sewage and Sullage	No lasting effect	Slight (E)
	Marine Discharges: Treated Utility Water, Chemical and Deck Drainage	No lasting effect	Slight (E)
	Marine Discharges: Putrescible Waste	No lasting effect	Slight (E)
	Marine Discharges: Produced water	No impacted expected	
	Marine Discharges: Cooling water	No lasting effect	Slight (E)
	Marine Discharges: Drilling Discharges	No lasting effect	Slight (E)
	Marine Discharges: Hydrotest Fluid	No lasting effect	Slight (E)
	Production Activities: Seabed Subsidence	No lasting effect	Slight (E)

Aspect Interaction Assessment and Conclusion

No lasting effect is predicted to occur to the tourism, recreation, or scientific studies values in the Project Area (and in particular Scott Reef). As described above, no significant cumulative impacts are expected to occur to the Scott Reef system or fauna that may be present in the surrounding waters. Given this, no significant cumulative impacts to tourism, recreation or scientific studies values are expected to occur as a result of the proposed Browse to NWS Project.

As such, the overall impact significance level of impacts on tourism, recreation and scientific studies has been assessed as Slight (E). As per the criteria outlined in **Section 6.2.3.4**, it is considered that the environmental objective for this receptor will be achieved and this impact is assessed as **Acceptable**.

Shipping (medium to high value user)

Table 9-18: Shipping cumulative assessment

Receptor	Shipping		
Local environment context	Shipping activity in and around the Browse Development Area is sparse, with the main commercial shipping routes located approximately 50 to 100 km west, intersecting the proposed BTL route at various locations, depending on the port. The main shipping activity in the NWMR relates to transits to and from Broome and transportation of goods between Australian and international ports. Major ports are adjacent to the Roebuck, Montebello and Dampier Commonwealth marine reserves (Section 5.4.2.4).		
Receptor sensitivity	**Medium/high value users** Busy shipping area is located outside of Project Area, but shipping traffic still likely to be high.		
Environmental objective	**Objective 21**: To not interfere with other marine users to a greater extent than is described in the draft EIS/ERD.		
Relevant aspects: Proposed Browse to NWS Project	***Aspect***	***Magnitude***	***Impact significance level***
	Physical Presence: Disturbance to Other Users	Slight	Minor (D)
Aspect Interaction Assessment and Conclusion			
Impacts to shipping will be limited to slight temporary impacts during construction of the proposed BTL and infrequent IMR activities. As no other activities are expected to impact shipping, no cumulative impacts to shipping are expected to occur as a result of the proposed Browse to NWS Project. The overall impact significance level of impacts on shipping has been assessed as Minor (D). As per the criteria outlined in Section 6.2.3.4, it is considered that the environmental objective for this receptor will be achieved and this impact is assessed as **Acceptable**.			

Industry (low value user)

Table 9-19: Industry cumulative assessment

Receptor	Industry		
Local environment context	The NWMR supports a number of industries including petroleum exploration and production, as well as minerals extraction. There are seven sedimentary petroleum basins in the NWMR: the Northern and Southern Carnarvon basins, Perth, Browse, Roebuck, Offshore Canning and Bonaparte basins. Of these, the Northern Carnarvon, Browse and Bonaparte basins hold large quantities of gas and comprise most of Australia's reserves of natural gas (Section 5.4.2.5).		
Receptor sensitivity	**Low value** The Project Area is not of extensive use by other Industry.		
Environmental objective	**Objective 21**: To not interfere with other marine users to a greater extent than is described in the draft EIS/ERD.		
Relevant aspects: Proposed Browse to NWS Project	***Aspect***	***Magnitude***	***Impact significance level***
	Physical Presence: Disturbance to Other Users	Slight	Negligible (F)

Aspect Interaction Assessment and Conclusion
Displacement of, or interference with, other oil and gas activities is not expected within the Browse Development Area. However, activities associated with the BTL, such as BTL installation, may result in short term interference, particularly at the NRC location (5-10 km away). No cumulative impacts to industry are expected to occur as a result of the proposed Browse to NWS Project. As such, the overall impact significance level of impacts on industry has been assessed as Negligible (F). As per the criteria outlined in **Section 6.2.3.4**, it is considered that the environmental objective for this receptor will be achieved and this impact is assessed as **Acceptable**.

Settlements (medium value users)

Table 9-20: Settlements cumulative assessment

Receptor	Settlements		
Local environment context	The proposed Browse to NWS Project presents potential social benefits and impacts to communities within WA and particularly Broome and the Dampier Peninsula, with Broome being the potential primary supply chain and logistics support location (**Section 5.4.4**).		
Receptor sensitivity	**Medium value users** Regionally important, low sensitivity to change.		
Environmental objective	**Objective 22**: To protect social surroundings from significant harm.		
Relevant aspects: Proposed Browse to NWS Project	***Aspect***	***Magnitude***	***Impact significance level***
	Atmospheric Noise Emissions	No lasting effect	Negligible (F)

Aspect Interaction Assessment and Conclusion
Atmospheric noise emissions from helicopters (transiting from logistic locations and the Project Area) are not predicted to have any lasting effect on settlements. Atmospheric noise emissions from helicopters are the only aspect predicted to result in potential impacts to settlements. As such, there are no predicted receptor-based cumulative impacts for settlements. As such, the overall impact significance level of impacts on settlements has been assessed as Negligible (F). As per the criteria outlined in **Section 6.2.3.4**, it is considered that the environmental objective for this receptor will be achieved and this impact is assessed as **Acceptable**.

Aboriginal and indigenous heritage (high value users)

Table 9-21: Aboriginal and indigenous heritage cumulative assessment

Receptor	Aboriginal and indigenous heritage		
Local environment context	No known sites of Aboriginal Heritage significance are located within the Development Area, according to the WA Department of Aboriginal Affairs' Aboriginal Sites Inquiry System. The existence of any unknown Aboriginal sites or artefacts of significance within the Browse Development Area, or the wider NWMR, is considered highly unlikely due to the site's remote location offshore (Section 5.4.3.1).		
Receptor sensitivity	**High value users** Browse Development Area is of high importance to stakeholders		
Environmental objective	**Objective 21**: To not interfere with other marine users to a greater extent than is described in the draft EIS/ERD.		
Relevant aspects: Proposed Browse to NWS Project	***Aspect***	***Magnitude***	***Impact significance level***
	Physical Presence: Disturbance to Other Users	Slight	Minor (D)
	Marine Discharges: Produced water	No lasting effect	Slight (E)
	Marine Discharges: Cooling water	No lasting effect	Slight (E)
	Marine Discharges: Drilling Discharges	No lasting effect	Slight (E)

Aspect Interaction Assessment and Conclusion

No impact to aboriginal heritage is expected to occur as a result of the proposed Browse to NWS Project.

Slight impacts to traditional Indonesian fisher utilising the MOU 74 area may occur as a result of the physical presence of infrastructure. As no lasting impacts to fish are predicted, no cumulative impacts to Indonesian fishers as a result of impacts to target species and disturbance from the physical presence of infrastructure are predicted.

As such, the overall impact significance level of impacts on settlements has been assessed as Minor (D) (based on the assessment of impacts of disturbance to other users from the physical presence of infrastructure on Indonesian fishers). As per the criteria outlined in Section 6.2.3.4, it is considered that the environmental objective for this receptor (Table 6-7) will be achieved and this impact is assessed as **Acceptable**.

It is noted that potential impacts associated with atmospheric emissions resulting from the onshore processing of the Browse gas by the NWS JV on the national heritage values of the listed National Heritage Place on the Dampier Archipelago (including aboriginal heritage values) are addressed in the North West Shelf Project Extension ERD (EPA 2186, EPBC 2018/8335).

Maritime archaeology

Table 9-22: Maritime archelogy cumulative assessment

Receptor	Maritime archelogy		
Local environment context	The Australian National Shipwreck Database and the WA Maritime Museum Shipwreck Database list one protected historic wreck within the Browse Development Area. The historic shipwreck of the Yarra is located at South Scott Reef. The Yarra was an iron barque vessel carrying a load of guano which struck the reef during a gale in 1884 (Section 5.4.3.2).		
Receptor sensitivity	**High value** Maritime archaeology protected by legislation exists within the Browse Development Area		
Environmental objective	**Objective 19**: To not have a substantial adverse impact on heritage values.		
Relevant aspects: Proposed Browse to NWS Project	***Aspect***	***Magnitude***	***Impact significance level***
	Physical Presence: Seabed Disturbance	No impact predicted	
	Production Activities: Seabed Subsidence	No impact predicted	
Aspect Interaction Assessment and Conclusion			
No impacts to the marine archaeology within the Project Area (i.e. shipwrecks at Scott Reef) are predicted and, therefore, no cumulative impacts to maritime archaeology are expected to occur as a result of the proposed Browse to NWS Project. As per the criteria outlined in Section 6.2.3.4, it is considered that the environmental objective for this receptor will be achieved and this impact is assessed as **Acceptable**.			

9.3 Overall Assessment of Risks from Unplanned Events or Incidents

Environmental risks from unplanned events or incidents may have significant consequences to multiple high value receptors on a regional scale. However, it is important to note that with the implementation of industry best practice mitigation and management measures by Woodside, a highly experienced operator, as well as significant legislative requirements and regulatory oversight, the likelihood of a significant risk event occurring and resulting in significant impacts is highly unlikely to remote.

Chapter 6 provides an assessment of the risk events identified during the impact and risk assessment. The following risks were identified as having a low risk rating due to the likelihood of the risk event occurring, along with the subsequent consequence:

- accidental dropped objects from vessels, the MODU or the FPSO facilities impacting benthic habitats – Section 6.3.1
- damage to unidentified maritime archaeology (ship or plane wrecks) during the placement of subsea infrastructure or the BTL and inter-field spur line – Section 6.3.1
- unplanned release of treated sewage and sullage above regulatory limits – Section 6.3.9
- unplanned release of treated utility water above regulatory limits – Section 6.3.10
- unplanned release of PW at significantly elevated discharge concentrations that would lead to water quality impacts within the State waters 3 nm boundary – Section 6.3.12
- unplanned release of cooling water at significantly elevated discharge concentrations that would lead to water quality impacts within the State waters 3 nm boundary – Section 6.3.13
- unplanned discharge of hazardous and non-hazardous inorganic waste – Section 6.3.14
- dispersal of drill cuttings and fluids being greater than predicted, resulting in impacts to high value Scott Reef shallow water benthic habitats (<75 m depth) be greater than predicted – Section 6.3.15
- unplanned discharge of subsea control fluid at a volume significantly greater than predicted – Section 6.3.16
- unplanned vessel interactions with marine turtles and fish (whale sharks) – Section 6.3.18.

Environmental risks that were ranked as moderate or high included the following:

- the risk posed by the potential higher utilisation of the Browse Development Area by pygmy blue whales and subsequent increased impact of underwater noise (moderate risk) – Section 6.3.8

- the unplanned vessel interactions with marine mammals (moderate risk) – **Section 6.3.18**
- the introduction and establishment of IMS at Scott Reef (moderate risk) – **Section 6.3.19**
- unplanned hydrocarbon releases (moderate to high risk) – **Section 6.3.21**.

It should be noted that the moderate and high-risk rating for these risks was driven by the significance of the potential consequences to high value receptors, on a regional scale. The likelihood of these risks occurring and resulting in subsequent impacts is considered highly unlikely to remote. It is also noted that different receptor groups would be impacted by each of the risk events. As such, it is considered that the likelihood of multiple risk events occurring, cumulatively resulting in a significant impact (inclusive of impacts from planned activities) on receptors, is remote.

With respect to the risks that are assessed as moderate or high risk, as significant impacts from one of these risk events could occur on a regional scale, cumulative impacts could take place if an unplanned risk event and other regional (natural or anthropogenic) stressors occurred at the same time. For example, a significant hydrocarbon spill impacting Scott Reef would potentially impact the recovery of the reef from recent natural perturbations (i.e. the 2016-2017 coral bleaching event). Likewise, the introduction and establishment of an IMS at Scott Reef could also potentially impact the ecosystem integrity of the reef system.

The planned mitigation and management actions for each of these risk events are described in **Chapter 6**. Given that the likelihood of any of these risk events occurring is considered unlikely to remote, the planned mitigation and management measures, and in consideration of the criteria outlined in **Section 6.2.3.4**, it is considered that the environmental objective for each receptor (**Table 6-7**) potentially impacted by these risk events will be achieved and, as such, these risks are assessed as **Acceptable**.

9.4 Mitigation, Management and Monitoring

Chapter 8 presents the overarching HSE management approach that Woodside will implement for the proposed Browse to NWS Project. It demonstrates the mitigation and management approach that Woodside will use to avoid environmental impacts and risks identified in this draft EIS/ERD or minimise them to an acceptable level. Where practicable, potential impacts have been avoided through the design and engineering process. Additional work will be undertaken during the detailed engineering phase of the proposed Browse to NWS Project to further refine design and reduce potential impacts.

Specific proposed measures to mitigate and manage unavoidable impacts from planned activities and reduce the environmental risk associated with unplanned events and incidents are presented in **Chapter 6**. These measures include compliance with regulatory requirements as well as industry best practice.

Central management and monitoring commitments for the proposed Browse to NWS Project include, but not limited to the following:

- Key management strategies:
  - Underwater noise monitoring of a RFSU operational well will be undertaken to inform an adaptive management approach for noise management for the TRD and TRE wells if required.
  - FPSO PW will be treated prior to being discharged overboard using a tertiary treatment system, such as a Macro Porous Polymer Extraction (MPPE) system that meets Woodside and accepted industry standards.
  - Project vessels will not travel at speeds greater than 12 knots with the State Proposal Area, or 6 knots in the Scott Reef channel.
  - Fast Crew Transfer Vessels (FCTVs) will operate under an approved FCTV Management strategy (to be detailed in subsequent Environment Plans as required) which will describe the appropriate additional control measures to manage vessel strike risk for the FCTV. Without additional engineering controls, FCTVs will not travel at speeds greater than 30 knots in sensitive areas at sensitive times.
  - Project vessels and MODUs will be subject to a risk assessment process to assess the likelihood of introducing IMS when transiting to the Project Area. Based on the outcomes of risk assessment, management measures commensurate with the risk (such as the treatment of internal systems, IMS inspections or cleaning) will be implemented.
  - Internationally sourced Project vessels and MODUs required within 3 nm of Scott Reef (State Proposal Area) for longer than 48 hours will be inspected by an experienced IMS expert/marine scientist for IMS; and cleaned where required[1].

---

[1] *Subject to confirmation, vessel/rig may be permitted re-entry within Scott Reef State waters (3 nm) without re-inspection provided its movements outside Scott Reef State waters at stationary or at slow speeds (less than three knots) in waters less than 50 metres deep do not exceed a period totalling greater than seven accumulative days prior to returning to Scott Reef State waters (3 nm).*

- Assurance:
  - Light monitoring will occur during drilling and completion of a well at TRE drill centre to verify modelling predictions.
  - Periodic and ‘for cause’ toxicity testing and characterisation of the physical and chemical composition of the PW stream prior to discharge will be undertaken.
  - During steady state FPSO operations, PW modelling and infield verification will be completed to verify the modelling predictions.
  - Baseline and periodic water and sediment quality monitoring at a gradient away from the FPSO facility in the receiving environment will be undertaken to detect changes because of FPSO PW discharge.
  - During steady state FPSO operations, cooling water modelling and infield verification will be completed to verify the modelling predictions.
  - Verification monitoring for seabed subsidence will be undertaken.
  - IMS surveillance program will be undertaken at Scott Reef, consisting of baseline survey prior to the commencement of activities in the State Proposal Area, and periodic surveys over the life of the proposed Browse to NWS Project.
  - Project vessels will not use heavy fuel oil or intermediate fuel oil.
- Verifying science:
  - Continuation of the Scott Reef long term monitoring program to monitor the functionality and status of the reef system, throughout the full lifecycle of the proposed Browse to NWS Project.
  - The existing pygmy blue whale data will be updated by targeted monitoring programs to verify impact predictions and inform adaptive management approaches at relevant times throughout the proposed Browse to NWS Project life cycle.
  - The existing turtle data will be updated by targeted monitoring programs to verify impact predictions at relevant times throughout the proposed Browse to NWS Project life cycle.
  - Targeted monitoring programs of pygmy blue whales and green turtles will be undertaken to verify impact predictions and inform adaptive management approaches at relevant times throughout the proposed Browse to NWS Project life cycle.

In the event that impacts cannot be avoided or mitigated to an acceptable level, an environmental offset plan will be developed as described in Section 8.7.

The measures presented in this draft EIS/ERD will be incorporated into activity-specific Environment Plans to be submitted for acceptance by NOPSEMA for Commonwealth waters and DMIRS for State waters, prior to the activity commencing where required. As described in Chapter 8, these Environment Plans will include strategies to reduce the impacts from planned (routine and non-routine) activities and risks from unplanned events and incidents to ALARP. In addition, EPs will include response strategies to be implemented in the highly unlikely event of a moderate to high risk event being realised.

9.5 Overall Assessment of Acceptability

This draft EIS/ERD presents the predicted impacts from planned activities and the environmental risks associated with unplanned events and incidents.

Chapter 6 presents the assessment of these impacts and risks for each aspect as well as an assessment of the acceptability of the impacts and risks in terms of the defined acceptability criteria which considers the Principals of ESD, the EPBC Act Significant Impacts Guidelines, the WA EPA Environmental Objectives, external and internal context and other requirements such as the requirements of the North-west Marine Parks Network Management Plan, specific EPBC Act conservation management and recovery plans and conservation advices for protected fauna. The conclusion of this assessment is that the impacts and risks presented by each aspect are **Acceptable**.

Section 9.2.2 presents an overall qualitative assessment of the cumulative impacts to the key sensitive receptors that may be affected by the proposed Browse to NWS Project. This assessment concludes that no significant receptor based cumulative impacts are expected to occur, the stated environmental objective for each receptor (Table 6-7) is expected to be achieved; and that the impacts to each sensitive receptor are **Acceptable**.

Section 9.3 presents an overall assessment of the environmental risks associated with unplanned events or incidents. The assessment finds that the stated environmental objective for each receptor (Table 6-7) is expected to be achieved and the overall risk posed in relation to unplanned events or incidents is **Acceptable**.

Chapter 7 presents the GHG emissions predicted to occur in a range of scenarios as a result of the proposed Browse to NWS Project and also provides a framework for consideration of those emissions in a cumulative context. The assessment details the emissions abatement measures that have been undertaken to date in the design process to reduce predicted emissions to an acceptable level. It also provides an overview of the potential benefits natural gas can present in the context of reducing global greenhouse gas emissions, whilst acknowledging the uncertainties associated with predicting future global greenhouse gas emissions. The assessment concludes that GHG emissions from the proposed Browse to NWS Project are considered **Acceptable**.

Finally, an assessment of the predicted impacts from the proposed Browse to NWS Project to the environment as a whole has been undertaken and is presented below. This assessment has been undertaken against the requirements of the principles of ESD and the objectives, requirements of the EPBC Act and EP Act, and other requirements such as the requirements of the North-west Marine Parks Network Management Plan and specific EPBC conservation plans.

Principles of Environmentally Sustainable Development

An assessment of the proposed Browse to NWS Project against the principles of ESD as defined in the EPBC Act is provided in Table 9-23.

Table 9-23 Assesment of proposed Browse to NWS Project against the principles of Environmentally Sustainable Development

Principles of ESD	Assessment
Decision making processes should effectively integrate both long-term and short-term economic, environmental, social and equitable considerations.	As described in Section 3.8, the selection of the concept for the proposed Browse to NWS Project was based on a set of primary drivers including environment, safety, economic performance and optimising economic recovery and supported by key drivers including global competitiveness, flexibility and robustness, stakeholder acceptance and marketability. The stakeholder acceptance driver is underpinned by the ability to achieve stakeholder alignment and government approvals, with all health, safety and environmental impacts and risks managed to an acceptable level, and to seek to apply inherently safe principles. Ongoing decision making will be driven by the objectives of the proposed Browse to NWS Project outlined in Chapter 2, which include the minimisation of the environmental footprint, managing HSE in accordance with industry standards and maximising socio-economic benefits. Chapter 7 presents a climate change impact assessment and concludes that Browse gas has the potential to play a significant role in enabling provision of clean and reliable energy as a partner to renewables. In addition, gas has the potential to contribute significantly to the reduction in global GHG emissions by displacing higher carbon intensive power generation (e.g. coal combustion). As such, it is considered that this principle of ESD has been considered in determining appropriate management and mitigation measures.
If there are threats of serious or irreversible environmental damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation.	Key aspects of the project will not result in any significant impacts (as defined in the MNES significant impact criteria) to endangered and vulnerable species—refer to Chapter 6. The available threatened species data (pygmy blue whales and green turtles), 2002 to 2017 and 2002 to 2010 respectively, were determined to be reliable and adequate for an assessment of impacts and risks to vulnerable species, and for the identification of suitable control measures, to ensure that the environmental objectives for the project are met. The existing data will be updated by a targeted monitoring program to verify impact predictions and inform adaptive management approaches at relevant times throughout the project life cycle, refer to Chapter 8, Table 8-1. Scientific knowledge will continue to be a key input into the detailed engineering phase and the implementation of the environmental mitigation, management and monitoring programs. Woodside has committed to the continuation of the Scott Reef long-term monitoring program to monitor the functionality and status of the reef system throughout the full lifecycle of the proposed Browse to NWS Project.

Principles of ESD	Assessment
The principle of inter-generational equity – that the present generation should ensure that the health, diversity and productivity of the environment is maintained or enhanced for the benefit of future generations.	As described above and in **Chapter 6** , all of the stated environmental objectives of the proposed Browse to NWS Project (**Table 6-7**) are predicted to be achieved and all impacts from planned activities have been assessed as acceptable. In addition, environmental risks have been reduced to an acceptable level, with the likelihood of significant impacts occurring as a result of unplanned events or incidents considered highly unlikely to remote. As such, it is considered that maintenance of the health, diversity and productivity of the environment will not be adversely impacted by the proposed Browse to NWS Project. Further, environmental benefits are expected to be realised as part of the ongoing monitoring of the remote reef systems within and outside the Project Area and research collaborations with appropriate science partners. Design and management measures set out in **Chapter 8** will ensure key environmental features in the Browse Development Area (Scott Reef) will be preserved for and accessible to future generations. As such, it is considered that this principle of ESD has been and will continue to be met.
The conservation of biological diversity and ecological integrity should be a fundamental consideration in decision making.	As described above and throughout this draft EIS/ERD, the conservation of biological diversity and ecological integrity has been and will continue to be integral to the decision making process associated with the proposed Browse to NWS Project. This is demonstrated by: + integration of conservation of biological diversity and ecological integrity into decision making during the selection of the development concept for the commercialisation of the Browse reservoirs + selection of environmental objectives that align with the principles of Ecologically Sustainable Development and the adoption of management and migration measures to achieve each objective + The commitment to manage operational discharges (PW and cooling water from the FPSO facilities) from the FPSOs to meet the defined threshold values (i.e. 99% species protection or lowest no effect concentration) at the State waters 3 nm boundary, 95% of the time + a commitment to manage drilling discharges (in particular bottom hole discharges) at drill centre locations in the State Proposal Area (i.e. TRA, TRD, TRE and TRF) in such a manner to avoid impacts to Scott Reef shallow water benthic communities and habitats (<75 m water depth) + monitoring programs for marine reptiles, cetaceans, and coral reef communities to verify impact predictions and aid management. As such, it is considered that this principle of ESD has been and will continue to be met.
Improved valuation, pricing and incentive mechanisms should be promoted.	In line with its corporate policies and procedures, Woodside will endeavour to use valuation, pricing and incentive mechanisms during procurements associated with the proposed Browse to NWS Project to balance economic and HSE outcomes. As such, it is considered that this principle of ESD has been and will continue to be met.

EPBC Act Controlling Provisions

An assessment of the proposed Browse to NWS Project against the MNES Significant Impact Guidelines for the controlling provisions is provided in **Table 9-24**. The significant impact criteria is provided in **Table 6-3**.

Table 9-24 Assessment of proposed Browse to NWS Project against the significant impact criteria for the controlling provisions

Controlling Provisions	Assessment
Listed Threatened Species and Ecological Communities	As per the overall impact assessment provided in **Section 9.2.2**: + No impact to any species listed as extinct in the wild is predicted as a result of the proposed Browse to NWS Project. + No significant impact is predicted to occur to any critically endangered, endangered or vulnerable species. This includes no significant impact, at a population level, to a species habitat (including habitat critical to a species survival) or to a species breeding cycle as a result of the proposed Browse to NWS Project. + The proposed Browse to NWS Project is not expected to affect the recovery of any species that has a species recovery plan in place (see EPBC conservation management plans below). + The likelihood that the proposed Browse to NWS Project results in the introduction and establishment of IMS or disease that may affect listed threatened species has been assessed as Remote. + No impact to Threatened Ecological Communities is predicted as a result of the proposed Browse to NWS Project. The environmental objectives for the proposed Browse to NWS Project have been developed in consideration of the significant impact criteria outline in **Table 6-5**. The assessment has concluded that all environment objectives relevant to listed threatened species are predicted to be achieved. As such, no significant impacts, as defined by MNES Significant Impact Guidelines, are expected to occur in relation to this controlling provision.
Listed Migratory Species	As per the impacts and risk assessment provided in **Chapter 6** and cumulative impact assessment provided above: + It is not expected that the proposed Browse to NWS Project will modify, destroy, fragment or isolate important areas for migratory species. + The proposed Browse to NWS Project is not expected to result in the introduction and establishment of IMS or disease that may affect listed threatened species. + It is not expected that the proposed Browse to NWS Project will seriously disrupt the lifecycle of an ecologically important proportion of the population of a migratory species. The environmental objectives for the proposed Browse to NWS Project have been developed in consideration of the significant impact criteria outline in **Table 6-5**. The assessment has concluded that all environment objectives relevant to listed migratory species are predicted to be achieved. As such, the assessment has concluded that no significant impacts, as defined by MNES Significant Impact Guidelines, are expected to occur in relation to this controlling provision.

Controlling Provisions	Assessment
The Commonwealth marine area, the protected matter being the environment generally.	As per the impacts and risk assessment provided in **Chapter 6** and cumulative impact assessment provided above: + The proposed Browse to NWS Project is not expected to result in the introduction and establishment of IMS or disease that may affect listed threatened species. + It is not expected that the proposed Browse to NWS Project will modify, destroy, fragment, isolate or disturb substantial areas of habitat, such that an adverse impact results in a reduction of marine ecosystem function or integrity within the Commonwealth marine area. + It is not expected that the proposed Browse to NWS Project will have a substantial adverse effect on a population of a marine species, including its life cycle and distribution. + It is not expected that the proposed Browse to NWS Project will result in a substantial change in air quality or water quality (including temperature) which may adversely impact on biodiversity, ecological integrity, social amenity or human health. + It is not expected that the proposed Browse to NWS Project will result in persistent organic chemicals, heavy metals, or other potentially harmful chemicals accumulating in the marine environment such that biodiversity, ecological integrity, social amenity or human health may be adversely affected. + It is not expected that the proposed Browse to NWS Project will have a substantial adverse impact on heritage values of the Commonwealth marine area, including damage or destruction of an historic shipwreck or plane wreck. The environmental objectives for the proposed Browse to NWS Project have been developed in consideration of the significant impact criteria outline in **Table 6-5**. The assessment has concluded that all environment objectives relevant to the Commonwealth Marine Environment are predicted to be achieved. As such, the assessment has concluded that no significant impacts, as defined by MNES Significant Impact Guidelines, are expected to occur in relation to this controlling provision.
National heritage values of a National Heritage Place	There are no National Heritage Places identified within the Project Area that may be affected by the proposed Browse to NWS Project. The assessment of any potential impacts on the national heritage values, including aboriginal heritage values, of the listed National Heritage Place on the Dampier Archipelago that may be associated with the onshore processing of the Browse gas by the NWS JV, is addressed within the ERD associated with the North West Shelf Project Extension Proposal (EPA 2186, EPBC 2018/8335).

WA EPA Environmental Objectives

An assessment of the State waters component of the proposed Browse to NWS Project against the relevant WA EPA's Environmental Objectives (as determined by the WA EPA) is provided in **Table 9-25**.

Table 9-25 Assessment of State waters component of the proposed Browse to NWS Project against the relevant WA EPA Environmental Objectives

EPA Environmental Objective	Assessment
Benthic Communities and Habitats - To protect benthic communities and habitats so that biological diversity and ecological integrity are maintained.	As per the impacts and risk assessment provided in **Chapter 6** and above, the environmental objectives in relation to deepwater benthic habitat (>75 m water depth) and Scott Reef shallow water benthic habitats (<75 m water depth) are predicted to be met. As detailed in **Chapter 8** and as recommended in the WA EPA Technical Guidance – Protecting the Quality of Western Australia's Marine Environment (EPA, 2016), Levels of Ecological Protection (LEPs) have been assigned within the State Proposal Area which include a maximum LEP for all Scott Reef shallow water benthic communities (<75 m water depth) and the majority of deepwater benthic communities (> 75 m water depth) during both construction and operations. A Environmental Quality Management Plan will be prepared and implemented to achieve these LEPs. As such, it is predicted that the WA EPA environmental objective *"to protect benthic communities and habitats so that biological diversity and ecological integrity are maintained"* will be achieved.
Marine Environmental Quality - To maintain the quality of water, sediment and biota so that environmental values are protected.	As per the impacts and risk assessment provided in **Chapter 6** and above, the environmental objectives in relation to marine environmental quality (specifically sediment quality, water quality and biota) are predicted to be met. As detailed in **Chapter 8** and as recommended in the WA EPA Technical Guidance – Protecting the Quality of Western Australia's Marine Environment (EPA, 2016), Levels of Ecological Protection (LEPs) have been assigned within the State Proposal Area which include a maximum LEP for all Scott Reef shallow water benthic communities (<75 m water depth) and the majority of remaining State Proposal area, with High or Moderate LEPs assigned directly around the proposed subsea infrastructure within deepwater benthic communities (> 75 m water depth) during both construction and operations. An Environmental Quality Management Plan will be prepared and implemented to achieve these LEPs. As such, it is predicted that the WA EPA environmental objective *"to maintain the quality of water, sediment and biota so that environmental values are protected"* will be achieved.
Marine Fauna - To protect marine fauna so that biological diversity and ecological integrity are maintained.	As per the impacts and risk assessment provided in **Chapter 6** and above, the environmental objectives in relation to marine fauna (specifically seabirds and migratory shorebirds, fish, marine mammals, marine reptile, epifauna and infauna) are predicted to be met. As per the impacts and risk assessment provided in **Chapter 6** and cumulative impact assessment presented in **Section 9.2**, no significant impacts to marine fauna, including their life cycle or distribution are expected to occur. Potential impacts that may occur are expected to be limited to temporary behavioural (avoidance) impacts as a result of noise emissions, however, these are not expected to be significant. As such, it is predicted that the WA EPA environmental objective *"To protect marine fauna so that biological diversity and ecological integrity are maintained"* will be achieved.
Air Quality - To maintain air quality and minimise emissions so that environmental values are protected.	No significant impacts to air quality from offshore atmospheric emissions are expected to occur as a result of the proposed Browse to NWS Project. As such, it is predicted that the WA EPA environmental objective *"To maintain air quality and minimise emissions so that environmental values are protected"* will be achieved" . Atmospheric Emissions from third party processing of Browse Gas are addressed in the NWS JV 'North West Shelf Project Extension ERD' (EPA 2186, EPBC 2018/8335).

North-west Marine Parks Network Management Plan

As described in Section 9.2.2.2, the proposed BTL route traverses the Multiple Use Zones (IV) of the Argo-Rowley Terrace and Kimberley Marine Parks. It should also be noted that the proposed BTL route passes approximately 2 km from the boundary of the Mermaid Reef Marine Park National Park Zone. Rationale for the route selection of the BTL is provided in Chapter 3.

The conservation values and objectives of the marine parks are outlined in the North-west Marine Parks Network Management Plan (Director of National Parks, 2018).

Impacts to AMPs will occur as a result of the permanent installation of the proposed BTL and temporarily due to vessel-based marine discharges of cooling water, putrescible waste and sewage and sullage during construction and IMR activities.

The impact of seabed disturbance on the Multiple Use Zone of the two AMPs has been minimised as far as practicable during the route selection process (Chapter 3). Impacts have been assessed as negligible as the area traversed by the proposed BTL represents a small proportion of the total area of the AMPs and the activities are considered to be consistent with the objective of the Multiple Use Zone (VI) to provide for ecologically sustainable use and the conservation of ecosystems, habitats and native species.

As described in Chapter 6, given their temporary and transient nature, the impact of the vessel-based marine discharges is not expected to result in any lasting effect on the values of the two AMPs traversed (i.e. the Kimberley Marine Park and Argo-Rowley Terrace Marine Park). As such, no cumulative impacts are expected to occur to AMPs as a result of marine discharges and seabed disturbance related to the installation of the subsea infrastructure.

As such, it is considered that the proposed activities are not inconsistent with the requirements of the North-west Marine Parks Network Management (Director of National Parks, 2018).

Assessment against EPBC conservation plans

Wildlife Conservation Plan for Migratory Shorebirds

Sandy Islet is used for roosting by seabirds and supports minor seabird breeding colonies, including for the little tern. Scott Reef is recognised as a resting BIA for the little tern. The Wildlife Conservation Plan for Migratory Shorebirds (Commonwealth of Australia, 2015a) has an objective that “Anthropogenic threats to migratory shorebirds in Australia are minimised or, where possible, eliminated”.

Mitigation and management measures described in Chapter 6 (particularly with respect to light emissions (Section 6.3.3), atmospheric noise emissions (Section 6.3.7), hazardous and nonhazardous waste (Section 6.3.14) and unplanned hydrocarbon releases (Section 6.3.21)), have been specifically developed to reduce the impact of planned activities and reduce the risk of unplanned events and incidents to an acceptable level.

As described in Section 9.2.2.2, the overall impact significance level of impacts on seabirds and migratory shorebirds has been assessed as Minor (D), based on the assessment of impacts resulting from light emissions (Minor (D)) and atmospheric noise (Slight (S)). These impacts are predicted to be limited to temporary behavioural impacts. Therefore, it is considered that the proposed activities are not inconsistent with the Wildlife Conservation Plan for Migratory Shorebirds (Commonwealth of Australia, 2015a).

The Recovery Plan for Marine Turtles in Australia (2017-2027)

Sandy Islet and the surrounding waters (20 km internesting buffer) are recognised as habitat critical to the survival of green turtles for the Scott Reef-Browse Island genetic stock in the Recovery Plan for Australian Marine Turtles 2017-2027 (Commonwealth of Australia, 2017) (Figure 5-27). In addition, a BIA exists for internesting green and hawksbill turtles around Sandy Islet. (Figure 5-26).

The Recovery Plan for Marine Turtles in Australia (2017-2027) (Commonwealth of Australia, 2017) has specific requirements to:

- Manage anthropogenic activities to ensure marine turtles are not displaced from identified habitat critical to the survival.
- Manage anthropogenic activities in BIAs to ensure that biologically important behaviour can continue.
- In relation to the Scott Reef – Browse Island green turtle genetic stock, the priority action is to manage anthropogenic activities to ensure marine turtle populations are not displaced from identified habitat critical to their survival.

Mitigation and management measures described in Chapter 6 (particularly with respect to light emissions (Section 6.3.3), underwater noise emissions (Section 6.3.8) and unplanned hydrocarbon releases (Section 6.3.21)) have been specifically developed to reduce the impact of planned activities and reduce the risk of unplanned events and incidents to an acceptable level.

As described in **Section 9.2.2.2**, the overall impact significance level of impacts on marine turtles has been assessed as Minor (D), based on the assessment of impacts resulting from underwater noise emissions (Minor (D) and light emissions (Minor (D)). These impacts are predicted to be limited to temporary behavioural impacts which are not expected to reduce nesting success. No displacement of marine turtles from identified habitat critical to the survival is predicted.

Therefore, it is considered that the proposed activities are not inconsistent with the objectives of the Recovery Plan for Marine Turtles in Australia (2017-2027) (Commonwealth of Australia, 2017).

Conservation Management Plan for the Blue Whale

The Project Area overlaps the pygmy blue whale migration BIA and possible foraging area located at Scott Reef, as identified in Conservation Management Plan for the Blue Whale (Commonwealth of Australia, 2015b). The conservation plan identifies noise interference and vessel disturbance as threats to the recovery of pygmy blue whales and notes an action that “Anthropogenic noise in biologically important areas will be managed such that any blue whale continues to utilise the area without injury, and is not displaced from a possible foraging area”.

Mitigation and management measures described in **Chapter 6**(particularly with respect to underwater noise emissions (**Section 6.3.8**), unplanned vessel interactions with fauna (**Section 6.3.18**) and unplanned hydrocarbon releases (**Section 6.3.21**)) have been specifically developed to reduce the impact of planned activities and reduce the risk of unplanned events and incidents to an acceptable level.

As described in **Section 9.2.2.2**, the overall impact significance level of impacts on marine mammals has been assessed as Minor (D). The impacts from underwater noise emissions have been assessed as minor. Behavioural modification of pygmy blue whales accessing a possible foraging area is not predicted as only 2% of the potential foraging area is predicted to be ensonified at levels above behaviour impact thresholds, leaving 98% of the possible foraging area available to pygmy blue whales and uninterrupted foraging. Potential impacts are likely to be restricted to a small number of individuals that may be travelling through the area and have been demonstrably minimised.

Therefore, it is considered that the proposed activities are not inconsistent with the Conservation Management Plan for the Blue Whale.

Overall conclusion

Woodside has considered the outcomes of the impact and risk assessment process and developed a range of mitigation and management measures to be implemented throughout the life cycle of the proposed Browse to NWS Project. In consideration of the unique values of Scott Reef and surrounds, the principles of ESD, the objects of the EPBC Act and EP Act and other relevant requirements, Woodside has concluded that the nominated environmental objectives for the proposed Browse to NWS Project will be met, the predicted impacts from planned activities and the potential risks from unplanned events and incidents have been reduced to an **Acceptable** level and that the proposed Browse to NWS Project can be implemented in a manner that will result in significant socio-economic benefits, while avoiding unacceptable environmental impacts.

EIS Guidelines / Environmental Scoping Document

Browse to North West Shelf Project

(EPBC 2018/8319, EPA 2191)

Under Environment Protection and Biodiversity Conservation Act 1999 (Cwlth)

and

Part 4 of the Environmental Protection Act 1986 (WA)

July 2019
Rev 2

TABLE OF CONTENTS

1. INTRODUCTION

1.1 Background

1.1.1 Overview of Browse to North West Shelf Project

The Browse Joint Venture (BJV) propose to develop the Brecknock, Calliance and Torosa fields (collectively known as the Browse resources) using two 1100 Million standard cubic feet per day (MMscfd) (annual daily export average) Floating Production Storage and Offloading (FPSO) facilities. The FPSO facilities will be supplied by a subsea production system and will transport gas to existing North West Shelf (NWS) Project infrastructure via a ~85 km spur line and a ~900 km Browse Trunkline (BTL), which will tie in near the existing North Rankin Complex (NRC) (note NRC is owned by North West Shelf Joint Venture (NWS JV).

Woodside Energy Ltd (Woodside) is Operator for and on behalf of the BJV (Woodside Browse Pty Ltd, Shell Australia Pty Ltd (Shell), BP Developments Australia Pty Ltd (BP), Japan Australia LNG Pty Ltd (MIMI Browse) and PetroChina International Investment (Australia) Pty Ltd (PetroChina)).

In September 2018, the proposed Browse to NWS Project entered Concept Definition phase. The proposed Browse to NWS Project is predominately based on proven technologies, including:

- two floating production storage and offloading (FPSO) facilities delivering around 11.4 Mtpa of LNG/LPG and domestic gas; and
- an approximately 900 km pipeline to existing NWS infrastructure.

Optimisation studies and other assessments are ongoing, which may result in changes being made to the reference case.

1.1.2 Project History

Woodside has conducted multiple ‘Concept Select’ phases for the Browse reservoirs; and has undertaken various studies to characterise the environment and understand the impacts and risks associated with the various development concepts. Details of these studies are included in **Table 5** and **Table 11**. These studies have informed the environmental approvals process for two previous development concepts being:

- The James Price Point (JPP) development concept in 2010 which was progressed through both State and Commonwealth environmental approvals (upstream: EPBC 2008/4111, downstream: referral and request that the proposal be declared a derived proposal under Ministerial Statement 917).
- The FLNG development concept which was referred under the Environment Protection and Biodiversity Conservation Act 1999 (EPBC Act) (EPBC 2013/7079) and received approval in August 2015. Note that the portion of the FLNG development concept that lies in State waters (the Torosa Subsea Development) was also referred to the Western Australian Environmental Protection Authority (WA EPA) under the Environmental Protection Act 1986 (EP Act) in December 2014 and was determined to not require assessment by the WA EPA in February 2015.

Over a 7-month period between September 2016 and April 2017, the BJV completed a development concept narrowing process with the aim of having ‘line of sight to at least one globally competitive and investable development concept which all stakeholders can support’.

Since April 2017, this development concept has been progressed through the Concept Select phase. Engineering and technical studies appropriate for the Concept Select phase have confirmed the preliminary feasibility of the Browse to NWS development concept which is the subject of this Environmental Impact Statement Guidelines (EISG) / Environmental Scoping Document (ESD).

1.1.3 Environmental Assessment Process

1.1.3.1 Environmental Referrals

The Proposed Action was referred to the Department of the Environment and Energy (DoEE) under the EPBC Act in October 2018. On 22 February 2019, the DoEE advised Woodside that the delegate for the Minister for the Environment had determined that the Proposed Action is a controlled action and requires assessment and approval under the EPBC Act before it can proceed. This assessment would be by Environmental Impact Statement. The following controlling provisions were identified in the decision notice:

- National heritage values of a National Heritage place
- Listed threatened species and communities
- Listed migratory species
- Commonwealth marine area, the protected matter being the environment generally.

The Western Australian (WA) State waters component of the proposed Browse to NWS Project was referred to the WA Environmental Protection Authority (EPA) under the EP Act in October 2018. On 22 January 2019, the WA EPA determined that the Proposal requires assessment under Section 39 of the EP Act and set a Public Environmental Review (PER) level of assessment.

The determination identified the following WA EPA Environmental Factors as being relevant for the Proposal within State waters.

- Benthic Communities and Habitats
- Marine Environmental Quality
- Marine Fauna
- Air Quality.

The determination requires Woodside to prepare an Environmental Scoping Document (ESD) and set a public review period for the Environmental Review Document (ERD) of 6 weeks.

1.1.3.2 Assessment Process

The assessment of the Proposed Action under the EPBC Act and EP Act is planned to be undertaken as a coordinated assessment between the DoEE and WA EPA. The National Offshore Petroleum Safety and Environmental Management Authority (NOPSEMA) will be engaged to provide technical advice to the DoEE in relation to the assessment.

This approach includes the following:

- Simultaneous referrals for the Proposed Action/Proposal under the EPBC Act and EP Act, which was completed in October 2018.
- The development of an EIS Guidelines (EISG) / ESD (this document) which describes the proposed content of an Environment Impact Statement/Environmental Review Document (EIS/ERD). This EISG/ESD will be issued to DoEE and EPA for review and endorsement.
- The development of a single draft EIS/ERD document that is issued to DoEE and EPA for comment on adequacy and approval, prior to release for public comment.
- The preparation of a single final EIS/ERD document. The final EIS/ERD will be submitted to the DoEE and WA EPA for assessment and to be published.

- Decision on the acceptability of the Proposed Action by the Commonwealth and State.

The environmental assessment process including expected timeframes is provided in **Table 1**. Timeframe and schedule will be documented in a DoEE issued Client Service Charter.

Table 1 Environmental Assessment Process

Stage	Action	Timeframe/Schedule
Pre-referral	Project definition meeting between Woodside, WA EPA and DoEE	Completed
Referral	Simultaneous referrals for the Proposed Action under the EP Act and EPBC Act	Completed: 17 October 2018
	Agency and public comment on referrals and Woodside response	Completed: January 2019
	Level of Assessment set by DoEE	Completed:22 February 2019
	Level of Assessment set by WA EPA	Completed: 22 January 2019
Scoping	Woodside prepare draft EISG/ESD in consultation with DoEE, WA EPA and NOPSEMA	Completed: 3 May 2019
	DoEE and WA EPA approves EISG/ESD	Target: June 2019
Draft EIS/ERD	Woodside prepare draft EIS/ERD	Target: Mid 2019
	DoEE (in consultation with NOPSEMA) and WA EPA review draft EIS/ERD for adequacy	
	Woodside revise EIS/ERD and resubmit	
	DoEE (in consultation with NOPSEMA) and WA EPA approve release of draft EIS/ERD	
	Public comment on draft EIS/ERD	DoEE = 4 weeks EPA = 6 weeks
Final EIS/ERD	Woodside address public comments and prepare final EIS/ERD	
	DoEE and WA EPA review final EIS/ERD for adequacy	
	Woodside revise EIS/ERD and resubmit	
	DoEE (in consultation with NOPSEMA) and WA EPA approve release of final EIS/ERD	
Evaluation of Project Proposal	DoEE (in consultation with NOPSEMA) and WA EPA assess final EIS/ERD and prepare draft assessment reports and recommendations	
	Woodside review draft assessment reports and recommendations	
	DoEE (in consultation with NOPSEMA) and WA EPA assess final EIS/ERD and prepare final assessment reports and recommendations	
	Relevant Ministers make decision on project approval	Target: Q2 2020

Subsequent to a favourable decision on the acceptability of the proposed Browse to NWS Project, and prior to any development activity occurring in Commonwealth waters, Environment Plans (EPs) including Oil Pollution Emergency Plan (OPEP) will be developed for approval by NOPSEMA in accordance with the Offshore Petroleum and Greenhouse Gas Storage (Environment) Regulations 2009.

1.2 Purpose of the EISG/ESD

The EISG/ESD has been jointly developed by Woodside, the DoEE and the WA EPA to address assessment requirements specified in the EPBC Act and EP Act. In general, the EISG/ESD aims to describe the proposed content of the EIS/ERD and set the scope of studies required to allow assessment and decision on the appropriateness of the proposed Browse to NWS Project.

In relation to the EP Act, the purpose of the EISG/ESD is to define the form, content, timing and procedure of the ERD, required by s. 40(3) of the EP Act. The EPA requires that proponents use the ESD template for all proponent prepared ESDs, which is fulfilled in Section 3.

1.3 Scope of the combined EIS/ERD

A combined EIS/ERD document is proposed to meet Commonwealth and State requirements respectively. However, with respect to the WA EPA’s assessment under the EP Act, the scope of the Proposal is infrastructure and related activities within State waters.

The scope of the combined EIS/ERD document is limited to construction and operation of the upstream component of the proposed Browse to NWS Project including:

- development drilling, completion and well unload activities (drilling and completion) of the Brecknock, Calliance and Torosa reservoirs
- installation and commissioning of subsea infrastructure, including anchors and mooring lines, umbilicals, flowlines, flexible risers, and manifolds
- installation and commissioning of the Browse Trunkline (BTL) and inter-field spur line including tie-in to existing NWS Project infrastructure near NRC
- installation, hook-up and commissioning of the FPSO facilities
- operation of the subsea infrastructure, including wells/wellheads, umbilicals, flowlines, risers, and manifolds, including inspection, maintenance and repair activities
- operation of the FPSO facilities, including condensate stabilisation, storage and offtake, gas processing (CO_2 and water removal and gas compression) and export
- transmission of gas from the FPSO facilities to the NWS Project infrastructure tie in point
- inspection, maintenance and repair activities
- decommissioning of subsea infrastructure (including well plug and abandonment), BTL, inter-field spur line and FPSO facilities at the end of reservoir field life (approximately 50 years).

The transportation and processing of Browse resources from the tie in point near NRC will be undertaken via the use of existing NWS Project infrastructure, which are the subject of different joint venture arrangements. These activities are covered by separate referrals submitted by the NWS JV under the EP Act (Assessment number 2186) and EPBC Act (EPBC 2018/8335). The relationship between these activities will be explained in the EIS/ERD.

The Proposed Action will involve vessel and helicopter movements in order to support the offshore facilities; however, it is not dependent on the development of new onshore infrastructure in order to proceed.

As the location(s) for supply chain and logistics support infrastructure are not yet determined, vessel and helicopter movements from a range of potential locations to the proposed Browse to

NWS Project are being considered similar to the previously approved FLNG concept. Existing infrastructure and related services will be utilised.

1.4 EISG/ESD structure

To demonstrate assessment requirements specified by the DoEE and WA EPA for the preparation of an EISG/ESD have been addressed, and to facilitate review, this EISG/ESD has been divided in three parts:

- Section 2 - PART A Description of Proposed Action
- Section 3 - PART B Specific content of the combined EIS/ERD
- Section 4 - PART C State ESD.

2. PART A: DESCRIPTION OF PROPOSED ACTION

2.1 Proposed Project Area

The Browse hydrocarbon resource is located in the Brecknock, Calliance and Torosa reservoirs approximately 425 km north of Broome and approximately 290 km off the Kimberley coastline.

The Project area consists of:

- the proposed Browse Development Area comprising the Brecknock, Calliance and Torosa fields, the FPSO facilities and the subsea production systems, including wells. The proposed Browse Development Area is approximately 2,897 ha in size
- the pipeline corridor within which the proposed BTL and inter-field spur line will be located from the proposed Browse Development Area to the tie in point near NRC. The pipeline corridor is approximately 985 ha in size and lies entirely within Commonwealth waters.

The total size of the Project Area is approximately 3,827 ha (noting that approximately 55 ha of the pipeline corridor lies within the proposed Browse Development Area).

The Browse Development Area consists of seven petroleum retention leases under the *Offshore Petroleum and Greenhouse Gas Storage Act 2006* (OPGGS Act), the State *Petroleum (Submerged Lands) Act 1982* (PSL Act) and the *Petroleum and Geothermal Energy Resources Act 1967* (WA). Five of the leases (WA-28-R, WA-29-R, WA-30-R, WA-31-R and WA-32-R) are located in Commonwealth waters. Two leases (TR/5 and R2) are within the State jurisdiction.

The pipeline corridor runs approximately ~900 km south west from the Calliance/Brecknock FPSO facility to the tie-in point with the NWS Project infrastructure near NRC. The pipeline corridor also includes a ~85 km inter-field spur line connecting the Torosa FPSO to the Calliance/Brecknock FPSO.

2.2 Key Characteristic of proposed Browse to NWS Project

2.2.1 Overview

The proposed Browse to NWS Project comprises subsea infrastructure and two FPSO facilities connected to existing NWS Project infrastructure via a ~900 km trunkline. To achieve optimal hydrocarbon recovery, it is anticipated that in the order of 13 wells are required for Ready for Start-up (RFSU) of the two FPSO facilities, and up to 49 wells are currently anticipated over field life. Indicative numbers of wells are presented in **Table 2**. The number and locations of the wells are subject to detailed design and refinement. The final number and approximate locations of the development wells and an appropriate project-specific assessment of impacts will be presented in the EIS/ERD.

Seabed disturbance within the Project area is expected to be approximately 1,200 ha of the approximately 3,900 ha Project area (210 ha for subsea infrastructure and moorings plus 985 ha for the proposed BTL and inter-field spur line). These values are subject to refinement during the design process.

The proposed Browse Development Area is shown in **Figure 1**. The BTL and inter-field spur line route are shown in **Figure 2**.

Table 2 Proposed Development Components

Component	State waters*	Overall development*
Development well count (up to)	21	49 (including 20 wells at Calliance, 22 wells at Torosa and 7 wells at Brecknock)
Subsea infrastructure	Wellheads, manifolds, flowlines and umbilicals, (seabed disturbance approximately 20 ha)	Wellheads, manifolds, flowlines, umbilicals, risers, anchors and moorings (seabed disturbance approximately 210 ha)
Surface facilities	None	Two ~1100 MMscf/d (annual daily average) FPSO facilities
Browse Trunkline (BTL)	None	~900 km 42” diameter trunkline with adequate capacity for export of 1,800 MMscf/d (maximum of 2,150 MMscf/d)*.
Inter-field spur line	None	~85 km 34” diameter spur line with adequate capacity for export of up to 1100 MMscf/d (annual daily average).

*Subject to detailed design and refinement

2.2.2 Development Infrastructure

The proposed Browse to NWS Project comprises of the key infrastructure components listed in Section 1.2, and described in detail below.

Wells

It is anticipated that the proposed Browse to NWS Project will require drilling and completion of up to 49 production wells at the Brecknock, Calliance and Torosa reservoirs over the life of the Project. Production wells will be drilled from a number of central drill centres. The number and location of these wells and drill centres will depend on reservoir target areas, seabed bathymetry and features to optimise reservoir recovery. Up to an estimated 21 of the production wells will be located within State waters.

Subsea Infrastructure and Flexible Risers

The wells at each drill centre will be connected to manifolds to allow reservoir fluids to be carried from the wells to the manifolds. The manifolds connect the wells to corrosion resistant alloy (CRA) flowlines that are routed back to the FPSO facilities. Connection between the flowlines and the FPSO facilities is achieved using flexible risers through a Flowline End Termination (FLET) or riser base manifold. Other subsea infrastructure includes the FPSO anchors and mooring lines and potentially permanent moorings for support vessels.

Each of the subsea infrastructure types described above will be located in both State and Commonwealth waters except for the flexible risers, mooring turrets and permanent FPSO mooring anchors which are only located in Commonwealth waters.

FPSO Facilities

Two FPSO facilities are proposed for the development. The FPSO facilities will have ship-shaped hulls ((nominally 335 m (up to 370 m) long x 67 m wide x 35 m deep)) with approximately 1,000,000 barrels’ effective condensate storage. The FPSO facilities will be permanently moored on location by mooring turrets. The FPSO facilities will be located in Commonwealth waters.

BTL and Inter-Field Spur Line

An approximately 85 km 34” inter-field spur line will connect the Torosa FPSO facility to the 42” trunkline near Calliance/Brecknock FPSO. Gas will be exported from the FPSO facilities via the 42” carbon steel BTL that runs approximately 900 km south west from the Calliance/Brecknock FPSO facility to the tie-in point with the NWS Project infrastructure near NRC.

The entire length of the inter-field spur line and BTL will be located in Commonwealth waters.

2.2.3 Development Activities

Development Drilling

It is anticipated that a mobile offshore drilling unit (MODU), which is either moored or dynamically positioned, will be used to drill and complete the wells. A moored MODU is anticipated to be moored using anchors, suction piles or driven piles, similar but most likely smaller, than those used for the FPSO facilities. Production wells will be drilled to depths of between 3,500 and 4,500 m beneath sea level to intersect the reservoirs. Once the reservoir is reached, the well may be drilled at inclination (up to horizontally) to optimise the length of the well within the reservoir and the recovery of reservoir fluids. Wireline logging activities may be undertaken for formation evaluation during drilling. This may include Vertical Seismic Profiling (VSP) or other logging activities, which may contain radioactive sources.

Installation of Subsea Umbilicals, Risers and Flowlines (SURF)

Subsea infrastructure required for start-up will be installed prior to the arrival of the FPSO facilities, with further infrastructure installed throughout the life of the proposed development, as required. Subsea infrastructure such as manifolds, flowlines, umbilicals, mooring systems and risers will be transported to site by a combination of installation vessels and cargo barges. Subsea installation of equipment will be performed by specialist DP vessels. Subsea equipment will typically be lowered into place from a vessel with a crane. Up to 20 piles may be installed to secure the riser bases, if required. Installation and hook up of the equipment on the seabed is typically achieved using submersible Remotely Operated Vehicles (ROVs). The ROVs will also aid in commissioning processes.

Seabed preparation works may be required to position flowlines on a level surface, to provide stability to the subsea gathering system. Seabed preparation works will most likely be undertaken using ploughing and/or mass flow excavation techniques. Protection and additional stabilisation methods, such as trenching and rock placement, may also be required to limit potential damage to flowlines and subsea infrastructure.

Installation of FPSO facilities

A turret mooring system will be installed for each FPSO facility using a DP installation vessel. The configuration is expected to comprise three groups of six mooring lines per group (pending completion of mooring analysis), arranged around the turret. The turret mooring system will include a non-rotating component to support the mooring lines, risers and umbilicals. This configuration allows the facility to freely weathervane with prevailing metocean conditions. Once on location, each FPSO facility will be connected to the mooring system.

The mooring lines will be preferentially secured to the seabed by suction piles. The suction piles will typically be 6 m to 10 m in diameter, and up to 30 m in length, with each weighing approximately 450 tonnes.

Installation of BTL and Inter-Field Spur Line

The BTL and inter-field spur line will be installed via a pipelay vessel. Sections of pipe will be welded together on the vessel before being laid directly onto the sea floor from the stern of the vessel. Typically, these vessels are held in place via DP systems or conventional mooring systems. Initiation anchors may be required temporarily at each end of the pipeline to support installation. The pipeline pieces will typically be manufactured overseas and transported directly to the pipelay vessel by barge.

Commissioning

Once installation and hook up of subsea infrastructure is complete, the subsea infrastructure will be subject to pre-commissioning, which is required to test the integrity of the subsea infrastructure. This will be conducted using hydrotest fluids, whereby the flowline pressure will be monitored to detect leaks. Fluids will then be left in place to provide corrosion protection prior to the introduction of reservoir fluids. Hydrotest fluid will either be discharged to sea at depth or returned to the FPSO facilities and discharged overboard. Hydrotesting will also be conducted on the BTL and inter-field spur line. The majority of the BTL hydrotest water will be discharged directly to sea at the Brecknock/Calliance FPSO, while the hydrotest water from the inter-field spur line will be discharged directly to sea at the Torosa FPSO.

As the FPSO facilities will be constructed at an existing fabrication yard overseas, pre-commissioning of the facilities will be preferentially carried out at the yard, and may include checking, inspection, cleaning, tightness testing, drying and inerting and first fill of process chemicals and adsorbents for the gas treatment system.

2.2.4 Operations

Extraction

During operations, hydrocarbons extracted from the reservoirs will flow via christmas trees and manifolds through the flowlines to the FPSO facilities. The flow rate of hydrocarbons will be controlled by subsea choke valves at the wellheads. Subsea hydraulic control fluids will be used to operate the choke valves.

Processing

Processing on the FPSO facilities topsides commences with the reservoir fluids being separated into a gas stream and a liquid stream (condensate and process water (PW)). The condensate and PW are then further separated with the PW sent for treatment prior to discharge overboard.

The condensate stream is stabilised and sent to compartmentalised condensate storage tanks prior to offloading. The gas will be sent to an acid gas removal unit (AGRU) for treatment. It will then be dehydrated, cooled and compressed prior to export to the NWS infrastructure via the BTL.

Condensate Offload

Up to 50,000 bbls of condensate will be produced daily. Condensate will be loaded on to condensate tankers using flexible hoses every two to four weeks (depending on the production rate), resulting in approximately 12 to 24 oil tanker movements a year per FPSO facility. The oil tankers will then transport the condensate to market.

Gas Export

Transport of the dry gas to the NWS Project onshore processing facility will be via the inter-field spur line and BTL to the NWS infrastructure at NRC. Transportation of the Browse resources from the tie in point near NRC using existing third party trunkline infrastructure and processing of the gas onshore is outside the scope of the Proposed Action. Liquids will not be present in the inter-field spur line and BTL.

2.2.5 Inspection, Maintenance and Repairs

The facility subsea infrastructure is designed to require only minor degrees of intervention. Inspection and maintenance is undertaken to ensure the integrity of the infrastructure and identify any problems before they present a risk of loss of containment. Intervention may be required to repair identified problems. Subsea activities can be broadly categorised into the following groups:

- Inspection - the process of physical verification and assessment of components in order to detect changes to its as-installed state in comparison to previous or baseline inspections.

Typical subsea inspection activities may include visual inspection, cathodic protection (CP) surveys, side scan sonar / multi-beam echo sounding, photogrammetry, process composition testing, corrosion probes, corrosion mitigation checks, metocean and seismic monitoring, cathodic protection testing and non-destructive measurement / testing, which may be supported by ROV or diver.

- Maintenance - required at regular and/or planned intervals to prevent deterioration or failure of equipment, or to maintain performance or reliability before failure or unacceptable deteriorations occurs. Maintenance activities may include cycling of valves, and leak and pressure testing.
- Repair - activities required when a subsea system or component is degraded, damaged or has deteriorated to a level outside of acceptance limits as defined by design codes. Damage sustained may not necessarily pose an immediate threat to continued system integrity, but may present an elevated level of risk to safety, health and environment or production reliability. Repair activities may also be associated with response to an emergency scenario.

2.2.6 Decommissioning

At the end of the Development life, the facilities will be decommissioned in accordance with all applicable existing legislation and good oilfield practice at the time. Decommissioning will occur once the Brecknock, Calliance and Torosa reservoirs have reached the end of their economic life and may occur in stages. This will likely include well suspension and plugging and abandoning wells.

2.2.7 Communications

Due to the distance of the proposed Browse to NWS Project from the mainland, a reliable high-speed communication network will be required between facilities offshore and the mainland. The network will be supplied by connection to an existing fibre optic cable.

2.2.8 Support Activities and Helicopters

The drilling and completion, installation and commissioning phases will be supported by barges, tugs, survey vessels, supply vessels (thereafter referred to as support vessels) and installation and pipelay vessels. Vessel requirements during the decommissioning phase are unknown at this stage due to uncertainty regarding the methodology to be applied, but it can be expected that decommissioning will use similar vessels to those engaged for installation activities.

The operations phase will require a small number of vessels in attendance in the vicinity of the FPSO facilities for transporting personnel, stores and equipment on a routine basis. The supply vessels will travel between the supply chain and logistics support facility (or facilities) and the FPSO facilities, while tugs will travel to the facility to support offloading as required.

Transfer to offshore facilities will be via helicopter or vessel. It is anticipated that up to two personnel transfers a week per FPSO facility will be required during normal operations. In times of high activity such as crew changes, shutdowns and major maintenance, it is anticipated that there could be two to three flights per day, or equivalent vessel transfers, per facility.

2.2.9 Development Schedule

Subject to all necessary joint venture and regulatory approvals being obtained and appropriate commercial arrangements being finalised, the indicative timeframes for the proposed Browse to NWS Project are as follows:

- commencement of construction and drilling and completion activities from approximately 2021 – 2022,
- followed by installation and commissioning activities,

- RFSU and commencement of operations occurring in the mid-2020s, and
- operations continuing for up to 50 years.

Following operations, decommissioning activities will be carried out as part of the Proposed Action.

3. PART B: SPECIFIC CONTENT OF THE EIS/ERD

3.1 Information and Advice Related to the Preparation of an EIS/ERD

3.1.1 The Objectives of the EIS/ERD

Environmental impact assessment depends on adequately defining those elements of the environment that may be affected by a proposed development, and on identifying the significance, risks and consequences of the potential impacts of the Proposed Action at a local, regional and national level. The EIS/ERD will be a significant source of information on which the public and government decision-makers will assess the potential environmental impacts of the Proposed Action.

It is expected that additional ecological and socio-economic investigations will be required to be undertaken to provide sufficient information for the EIS/ERD. The nature and level of investigations will be related to the likely extent and gravity of the potential impacts (likelihood, consequence, magnitude, extent and scale of impacts, including worst case scenarios). All relevant impacts of the Proposed Action on MNES and the State waters proposal on WA EPA environmental factors are to be investigated and analysed, and commitments to avoid, mitigate and offset any adverse impacts are to be detailed in the EIS/ERD.

The aims of the EIS/ERD and public review process are:

- to provide a source of information from which interested individuals and groups may gain an understanding of the Proposed Action, the need for the Proposed Action, the alternatives, the environment which it could potentially affect, the impacts that may occur and the measures proposed to be taken to avoid or minimise these impacts
- to provide a forum for public consultation and informed comment on the Proposed Action
- to provide a framework in which decision-makers can consider the environmental aspects of the Proposed Action including biophysical, cultural, social, heritage, economic, technical and other factors (as applicable).

The EIS/ERD will discuss compliance with the objectives of the EPBC Act, EP Act and the principles of ecologically sustainable development, as set out in the EPBC Act. The EIS/ERD will also identify and address, as fully as possible, all matters relevant to the Proposed Action and State waters proposal and their potential impacts.

The EIS/ERD will provide a description of the existing environment in the area affected by the Proposed Action and any decommissioning of existing infrastructure, construction, operations and future decommissioning proposed. All potential impacts and risks on the environment are to be investigated and analysed. The EIS/ERD will present an evaluation of the potential environmental impacts using an accepted risk-based methodology and describe proposed measures to avoid, minimise or offset the expected, likely, or potential impacts. Any prudent and feasible alternatives will be discussed in detail and the reasons for selection of the preferred option will be clearly given. The State waters proposal will be similarly assessed.

3.1.2 General Advice

The EIS/ERD will be a stand-alone document. It will contain sufficient information from studies and/or investigations undertaken to avoid the need to refer to previous or supplementary reports. Headers and/or footers will be used to denote which section the page relates to (i.e. based on the table of contents).

The EIS/ERD will enable interested stakeholders and the assessing agencies to understand the environmental consequences of the proposed development. Information provided in the EIS/ERD will be objective, clear, succinct and, where appropriate, be supported by maps, plans, diagrams or other descriptive detail. The body of the EIS/ERD is to be written in a style that is easily understood by a member of the public. Technical jargon will be avoided wherever possible and a full glossary included. Cross-referencing will be used to avoid unnecessary duplication of text.

If it is necessary to make use of material that is considered to be of a confidential nature, the proponent will consult with the DoEE and WA EPA on the preferred presentation of that material, before submitting it for approval for publication.

Detailed technical information, studies or investigations necessary to support the main text will be included as appendices issued with the EIS/ERD. Any additional supporting documentation and relevant studies, reports or literature not normally available to the public from which information has been extracted will be made available at appropriate locations during the period of public display of the EIS/ERD.

Where specific information requirements are set out within this EISG/ESD, they should be read as a requirement for as much detail as is appropriate and reasonably available at this stage of planning. The EIS/ERD will clearly identify any gaps in the information presented and include discussion on the effect of these gaps on the overall results of the assessment and possible methods for addressing them.

An executive summary will be provided and made available as a stand-alone document for public information.

The EIS/ERD will state the criteria adopted in assessing the Proposed Action and its potential impacts, such as: compliance with relevant legislation, policies, standards and best practice; community acceptance; maximisation of environmental benefits (if any); and minimisation of risks and harm. The State waters proposal will be similarly assessed.

Any and all unknown variables or assumptions made in the assessment will be clearly stated and qualified. The extent to which the limitations, if any, of available information may influence the conclusions of the environmental assessment will be discussed.

Woodside will ensure that the personnel providing information to address this EIS/ERD have the relevant qualifications and experience in their relevant fields.

The EIS/ERD will comprise three elements:

a) The executive summary
b) The main text of the document, written in a clear and concise manner so as to be readily understood by a member of the public.
c) Appendices containing a copy of this EISG/ESD and detailed technical information which may include other sensitive commercial or cultural information (if required).

The EIS/ERD will be written so that any conclusions reached can be independently assessed. To this end all sources will be appropriately referenced.

3.2 Invitation to make a submission

The draft EIS/ERD will include an invitation to make a submission including:

1. details on how and when public submissions will be addressed in the assessment and decision-making process
2. how submissions can be made
3. what form submissions should take
4. when submissions should be made.

3.3 Executive Summary

An executive summary that outlines the key findings of the EIS/ERD will be provided. The executive summary will briefly:

1. state the background and the need for the Proposed Action and State waters proposal.
2. discuss alternatives to the Proposed Action, State waters proposal and the reasons for selecting the preferred option and rejecting alternatives
3. summarise the installation, operational and decommissioning activities associated with putting the Proposed Action and State waters proposal into practice
4. state the proposed schedule for key activities and the expected duration of the Proposed Action and State waters proposal
5. provide an overview of the existing regional and local environments, summarising the features of the physical, biological, social and economic environment relating to the Proposed Action, State waters proposal and associated activities with each
6. describe the expected, likely and potential impacts of the Proposed Action and State waters proposal on the environment during the installation, operational and decommissioning phases
7. summarise the environmental protection measures and safeguards, monitoring and decommissioning procedures to be implemented for the Proposed Action and State waters proposal
8. provide an outline of the environmental record of Woodside.

3.4 General Information

The EIS/ERD should provide the background of the proposed Browse to NWS Project including:

1. the title of the action
2. the full name and postal address of the designated proponent
3. a clear outline of the objective of the action
4. the location of the action
5. the background to the development of the action
6. how the action relates to any other actions (of which the proponent should reasonably be aware) that have been, or are being, taken or that have been approved in the region affected by the action
7. the current status of the action
8. the consequences of not proceeding with the action
9. a brief explanation of the scope, structure and legislative basis of the EIS/ERD

10. the specific EPBC Act MNES and WA EPA Environmental factors affected by the action
11. a description of government planning policies and statutory controls which will influence the proposed Browse to NWS Project. All applicable jurisdictions and areas of responsible authorities within the area will be listed and shown on maps at appropriate scales.

3.5 Description of the Action

3.5.1 Development Description

All installation, operational, IMR and decommissioning components of the action will be described in sufficient detail to understand the Proposed Action and State waters proposal and assist in determining the associated potential environmental impacts. This will include the location (including coordinates) of all works to be undertaken, structures to be built or elements of the action that may have relevant impacts (on MNES and/or WA EPA Environmental Factors) and other social or economic impacts. In addition, proposed safeguards and mitigation measures to deal with relevant impacts of the action will be included.

The description of the action will also include details on how the works are to be undertaken (including all stages of development and their timing) and design parameters for those aspects of the structures or elements of the action, including how the operation is to be managed, that may have relevant impacts and other social or economic impacts.

The description will include the use of aerial photographs, maps, figures and diagrams, where appropriate. A general location map will be provided that illustrates the existing and proposed infrastructure and will include the location of known potential future expansions or new developments in the vicinity. Reference will be made to detailed technical information in appendices where relevant.

The description will also include any other requirements for approval or conditions that apply, or that Woodside reasonably believes are likely to apply, to the Proposed Action or State waters proposal.

3.5.2 Feasible Alternatives

Any feasible alternatives to the action to the extent reasonably practicable, including:

1. if relevant, the alternative of taking no action and/or part of the Proposed Action and State waters proposal
2. a comparative description of the adverse and beneficial impacts of each alternative on MNES and WA Environmental Factors
3. sufficient detail to make clear why any alternative is preferred to another and if approval is being sought for feasible alternatives as part of this assessment process.

Short, medium and long-term advantages and disadvantages of the options will be discussed.

3.5.3 Social and Economic Matters

For the purpose of the assessment under the EPBC Act, information will be provided on the broader social and economic impacts (positive or negative) of the Proposed Action. Any information provided for this purpose will be in a separately identified section or appendix of the EIS/ERD. Such information provided may address:

1. the broader economic benefits of the Proposed Action going ahead versus alternatives
2. any effects on employment that may occur beyond the immediate scope of the Proposed Action (including versus alternatives). Any methodology used to calculate indirect effects associated with employment will be provided

3. information on the amount of domestic and/or overseas investment for capital infrastructure (including versus alternatives)
4. any other social or economic issues that may relate directly or indirectly.

3.6 Stakeholder Engagement

The EIS/ERD will provide details of any consultation in relation to the Proposed Action and State waters proposal including:

1. consultation that has already taken place
2. documented response or results of the consultation that has taken place
3. any further proposed consultation.

Woodside will consult with relevant stakeholders in relation to the proposed Browse to NWS Project. These stakeholders include decision-making authorities, other relevant government agencies and authorities (local, state, and Commonwealth), the local community, local indigenous groups, academics, research authorities and environmental non-government organisations. The EIS/ERD will describe the consultation method adopted, existing stakeholder forums and skills and techniques used to ensure effective communication of the nature and detail of proposed Browse to NWS Project. This will include the means used to identify concerns and to gauge and progress mitigation strategies.

The assessment documentation must provide details of the potential indirect impacts of the proposed action on the (Indigenous rock art) values of the Dampier Archipelago (including the Burrup Peninsula) National Heritage Place, and the extent to which these values may potentially be impacted by the proposed action following any planned mitigations.

3.7 Description of the Environment

3.7.1 Overview

Section 528 of the EPBC Act defines the environment as including:

(a) ecosystems and their constituent parts, including people and communities; and

(b) natural and physical resources; and

(c) the qualities and characteristics of locations, places and areas; and

(d) the social, economic and cultural aspects of a thing mentioned in paragraph (a), (b) or (c).

Subsection 3(1) of the EP Act defines the environment as meaning "… living things, their physical, biological and social surroundings, and interactions between all of these"

The EIS/ERD will include a detailed description of the environment within the Project Area and the surrounding areas (including State waters) that may be affected by the Proposed Action.

The environment that may be affected (EMBA) by the proposed Browse to NWS Project, which is the largest spatial extent where unplanned events could have an environmental consequence on the surrounding environment will be described. The spatial areas of the defined EMBA and Project Area will be used to identify and describe all environmental values, including environmental and socio-economic, that are relevant to the project. The relevant receptors (based on the preliminary impact and risk assessment) and their relationship with the MNES categories and the WA EPA Factors are presented in **Table 3** and **Table 4** respectively.

This EIS/ERD chapter will describe the following elements of the environment within the Project Area:

- Physical environment including
  - Climate and atmospheric characteristics
  - Oceanographic conditions, bathymetric and geotechnical information
  - Marine water and marine sediment characteristics
- Ecological environment including
  - An overall evaluation of the flora and fauna communities identified with reference to:
    - habitat values in a local, regional and national context
    - presence of endemic species
    - regional representation; conservation and biodiversity values
    - economic and cultural values of species
    - unique habitats.
  - Particular attention will be given to the conservation values within Scott Reef and surrounds (e.g. diverse aggregations of marine life, higher primary production relative to other parts of the regions, high species richness and heritage values) and their importance in a local, regional and national context as described in the Marine bioregional plan for the North-west Marine Region (Commonwealth of Australia 2012).
  - A broader description of the biodiversity and biogeography of the receiving environment, including the identification of sensitive environments along with key ecological relationships and interdependencies (e.g. coral spawning, fish spawning aggregations, flora and fauna relationships).
  - A description of listed threatened species and ecological communities (EPBC Act sections 18 & 18A), listed migratory species (EPBC Act sections 20 & 20A) and protected species under the Biodiversity Conservation Act 2016 that are likely to be present in the vicinity of the proposed Browse to NWS Project. Descriptions will include the predicted temporal and spatial variability in occurrence within the Project Area, known habitat utilisation or requirements and relevant identified threats to their survival. Details of the scope, timing and scientifically robust methodology for studies or surveys used to provide information on the listed species/communities/habitats at the site (and in areas that may be impacted by the project) will also be included. Species to be addressed in the EIS/ERD include, but are not be limited to the following. Additional EPBC Act listed threatened and listed migratory species will be considered following completion of the relevant modelling studies to be undertaken to determine the species that may be affected:
    - Pygmy blue whale (*Balaenoptera musculus brevicauda*)
    - Humpback whale (*Megaptera novaeangliae*)
    - Sei Whale (*Balaenoptera borealis*)
    - Fin Whale (*Balaenoptera physalus*)
    - Green Turtle (*Chelonia mydas*)
    - Loggerhead Turtle (*Caretta caretta*)
    - Leatherback Turtle (*Dermochelys coriacea*)
    - Hawksbill Turtle (*Eretmochelys imbricata*)

    - Olive Ridley Turtle (*Lepidochelys olicacea*)
    - Flatback Turtle (*Natator depressus*)
    - Common Noddy (*Anous stolidus*)
    - Streaked Shearwater (*Calonectris leucomelas*)
    - Lesser Frigatebird (*Fregeta ariel*)
    - Little Tern (*Stenula albifrons*)
    - Barn Swallow (*Hirundo rustica*)
    - Common Sandpiper (*Actitis hypoleucos*)
    - Green Sawfish (*Pristis zijsron*)
    - Large Sawfish (*Pristis prisis*)
    - Whale shark (*Rhincodon typus*).
  - A description of the marine environment (EPBC Act sections 23 & 24A and EP Act) relevant to the action, including, but not limited to, habitat, species and values of listed Western Australian and Commonwealth Heritage places, Key Ecological Features (identified in the relevant Marine Bioregional Plan) and Western Australian and Commonwealth Marine Parks including:
    - distance from the Proposed Action
    - reserve characteristics
    - status
    - IUCN category
    - Conservation value
    - relevant management strategies
  - Appropriate resources will be reviewed and cited throughout, including all relevant government issued conservation advice and recovery plans, and recent ecological studies where available (e.g. AIMS North West Shoals to Shore Research Program).
  - The extent of existing disturbance to flora and fauna, and the incidence of introduced pest species will be discussed.
- Socio-economic environment including:
  - a description of all existing uses and users of the Project Area including discussion of scientific research, tourism, commercial, traditional and recreational fishing, military areas and shipping routes (where relevant)
  - a description of government planning policies and statutory controls which will influence the project, surrounding areas of future, planned and current use. All applicable jurisdictions and areas of responsible authorities within the area will be listed and shown on maps at appropriate scales
  - any places with known or anticipated heritage, social or cultural values, such that they have been recognised with listing or recording under relevant State or Commonwealth legislation or are anticipated to be listed under such legislation
  - a description of any historic shipwrecks within the area pursuant to the Commonwealth Underwater Cultural Heritage Act 2018 (which will replace the Historic *Shipwrecks Act 1976* on 01 July 2019) and State *Maritime Archaeology Act 1973*, including locations.

3.7.2 Format of Chapter

The chapter will be set out in a format broadly similar to the following outline:

1. Existing Environment
    - 1.1. Receptor Group (e.g. Marine Fauna)
        - 1.1.1. Receptor (e.g. Marine Mammals)
            - 1.1.1.1. Background and Regional Overview
            - 1.1.1.2. Browse Development Area
                - 1.1.1.2.1. Scott Reef
                - 1.1.1.2.2. Remainder of area
            - 1.1.1.3. Trunkline and Inter field Spur-line Route

3.7.3 Relevant Receptors in relation to MNES and WA EPA Factors

Table 3 indicates the relevant receptors for the Proposed Action (based on the preliminary impact and risk assessment) and their relationship to the MNES.

Table 3 Relevant Receptors in relation to Matters of National Environmental Significance

Matters of National Environmental Significance	Physical Receptors					Ecological Receptors														Socio-Economic Receptors								
	Marine Sediments	Marine Water quality	Air Quality	Ambient Light	Ambient Noise	Planktonic Communities	Epifauna and Infauna	Coral	Seagrass	Macroalgae	Saltmarsh	Mangroves	Seabirds and Migratory Shorebirds	Fish	Marine Mammals	Marine Reptiles	Key Ecological Features	Australian Marine Parks	State Marine Parks and Reserves	Commonwealth Managed Fisheries	State Managed Fisheries	Tourism and Recreation	Shipping	Industry	Settlements	Other Protected Places	Indigenous heritage	Marine Archaeology

3.7.4 Previous studies to characterise the existing environment

Information on the existing environment for the EIS/ERD will primarily be drawn from existing literature and studies previously completed by Woodside including long-term monitoring. Woodside has commissioned approximately 60 studies within the proposed Browse Development Area, Scott Reef and the broader region that span approximately two decades. Studies have included baseline and annual programs for humpback whale, turtle, other marine megafauna and fish species in the region, as well as long-term monitoring of coral and fish communities at Scott Reef.

These studies have enabled Woodside to build a comprehensive understanding of the environmental context of developing the Browse resources, to enable identification of the potential environmental impacts and development of the appropriate measures to manage and mitigate these.

Further, Woodside has continued to support the undertaking of studies and monitoring programs for species and communities that exhibit marked temporal changes in population dynamics or spatial distribution variability. For example, AIMS has continued to monitor annual changes in coral and fish communities at Scott Reef (dataset 1993-2018). These studies have identified dramatic changes to Scott Reef related to the impact from cyclones and thermal-induced bleaching.

For species or communities that are unlikely to have major changes in either population numbers, seasonality or distribution patterns Woodside will utilise historical Woodside datasets (supplemented with any additional non-Woodside studies) to describe current receptors and inform the impact assessment. **Table 5** outlines the previous studies undertaken to support the potential development of the Browse resource.

Table 5 Previous studies undertaken to characterise the environment in relation to development of the Browse resource

A full index of previous Browse technical studies is available at https://www.woodside.com.au/our-business/burrup-hub/index-of-previous-browse-studies

3.7.5 Summary of Workplan

Although the development concept for the Browse resources has changed to the proposed Browse to NWS Project concept, the environmental footprint of the facilities and subsea infrastructure (other than the BTL and inter-field spur line) is expected to be similar to that of the FLNG development concept where a significant amount of work has already been undertaken, especially around Scott Reef.

An overview of the current level of understanding and workplan for each relevant receptor is provided in **Table 6**. The studies outlined in **Table 6** would inform the design and implementation of any environmental monitoring programs that may be mandated as part of the assessment process. Woodside notes that should environmental monitoring be required to verify impact predictions during construction and/or operations, appropriate studies may be required to inform the baseline status of some environmental receptors prior to monitoring.

Table 6 Existing Environment Workplan

Receptor Group	Receptor	Key Areas of Consideration	Assessment of Current Level of Understanding and information gaps	Environmental Studies Workplan
Physical	Marine sediments	Seabed in Browse Development Area, BTL corridor and surrounds	As there is likely to be little or no significant change to marine sediments within the Browse Development Area since previous studies were undertaken, Woodside will rely on historical datasets (~3 years collection period) to support existing environmental baseline knowledge. The basis for the baseline assessment of sediment quality values within the Browse Development Area are the findings from three principal surveys undertaken within the area (Brinkman et al., 2009a; Gardline Marine Services Pty Ltd, 2009a; URS Australia Pty Ltd, 2007). The most recent Gardline survey (2009) including sediment and analysis at 31 stations including seven at the Calliance field and eight at the Torosa field. The studies demonstrated that sediments within the Browse Development Area were generally classified as muddy sand with variable gravel components, with sediments at the Brecknock, Calliance and Torosa reservoirs generally soft silt and clay, with areas of sand and stiff, hard and/or cemented material (Fugro Survey Pty Ltd, 2006; Gardline Marine Services Pty Ltd, 2009a). No evidence of hydrocarbon contamination in sampled seabed sediments was reported in the Browse Development Area (Gardline Marine Services Pty Ltd, 2009a; URS Australia Pty Ltd, 2007). Gardline (2009a) reported that the concentration of total petroleum hydrocarbons (TPH) in all collected samples across the Browse Development Area was below the limits of detection (Gardline Marine Services Pty Ltd, 2009). With the exception of a slight exceedance in Ni concentrations at two locations and Hg concentrations at one location, metal concentrations (As, Cd, Cu, Cr, Co, Hg, Pb and Zn) in sampled sediments were below SQG-High trigger levels outlined in the revised Australian and New Zealand sediment quality guidelines (Simpson et al. 2013). The available studies and literature cited above provide a good understanding of the marine sediment quality within the Browse Development area. Given the nature of the marine sediments within the area and the lack of anthropogenic inputs, it is unlikely that there have been significant changes in the physical and chemical characteristics of the sediments. Consequently, these studies are deemed to provide a good understanding of the current marine sediment quality values within the Browse Development Area to support the impact assessment process for the project. In addition, such parameters will be used to support the interpretation of the discharge modelling results. However, there is currently a lack of specific information on marine sediment quality along the BTL route with current information limited to general regional values. As such an environmental survey is being undertaken to determine the sediment quality values along the proposed BTL route. This does not apply in the area near the NRC tie in point, where Woodside has a good understanding of marine sediment via studies undertaken in relation to existing Woodside assets and projects in the area. It also does not apply in the area adjacent to the Browse Development Area where studies have been undertaken in relation to the previously proposed pipeline route from Browse to James Price Point.	Literature review of Woodside information and publicly available information. Implementation of a marine environmental survey of the BTL corridor including sampling and characterisation of marine sediments.
Physical	Marine Water quality	Browse Development Area and BTL corridor and surrounds	As there is likely to be little or no significant change to water quality within the Browse Development Area since previous studies were undertaken, Woodside will rely on historical datasets (~3 years collection period) to support existing environmental baseline knowledge. As with marine sediments, the basis for the baseline assessment of water quality values within the Browse Development Area are the findings from three principal surveys undertaken within the area (Brinkman et al., 2009a; Gardline Marine Services Pty Ltd, 2009a; URS Australia Pty Ltd, 2007). The most recent Gardline survey (2009) including water sampling and analysis at 34 stations including seven at the Calliance field and eight at the Torosa field. The studies reinforced the fact that given the distance from potential contamination sources or anthropogenic inputs, water quality within the Browse Development Area is typical of an unpolluted tropical offshore environment within the North West Marine Region (NWMR) with low turbidity, nutrient poor oceanic waters. The studies undertaken, in particularly Gardline (2009), demonstrate the lack of anthropogenic contamination of the waters, with metal analyte levels below the limit of reporting (LoR), with concentrations of cobalt (Co), chromium (Cr), Cu, lead (Pb) and Ni at or below 0.001 mg/L. The available studies and literature cited above provide a good understanding of the marine water quality within the Browse Development area. Given the nature of the water quality and the lack of anthropogenic inputs, it is unlikely that there have been significant changes in the physical and chemical characteristics of the receiving environment. Consequently, these studies are deemed to provide a good understanding of the current marine water quality values within the Browse Development Area to support the impact assessment process for the project. In addition, such parameters will be used to support the interpretation of the discharge modelling results. However, there is currently a lack of specific information on marine water quality along the BTL route with current information limited to general regional values. As such an environmental survey is being undertaken to determine the baseline water quality values along the proposed BTL route. This does not apply in the area near the NRC tie in point, where Woodside has a good understanding of marine water quality via studies undertaken in relation to existing Woodside assets and projects in the area. It also does not apply in the area close the Browse Development Area where studies have been undertaken in relation to the previously proposed pipeline	Literature review of Woodside information and publicly available information. Implementation of a marine environmental survey of the BTL corridor including sampling and characterisation of marine water quality.

Receptor Group	Receptor	Key Areas of Consideration	Assessment of Current Level of Understanding and information gaps	Environmental Studies Workplan
			route from Browse to James Price Point.	
Physical	Air quality	Browse Development Area	Woodside has sufficient information on air quality in the Browse Development Area on the basis that the area is offshore and remote from urban or industrial areas; and as such is not likely to be significantly influenced by anthropogenic sources.	Literature review of Woodside information and publicly available information.
Physical	Ambient light	Browse Development Area and BTL corridor and surrounds	Woodside has sufficient information on ambient light in the Browse Development Area and BTL corridor on the basis that the area is offshore and remote from urban or industrial areas. Other than light emissions associated with the NRC facility, local light emissions via anthropogenic sources are limited to shipping.	Literature review of Woodside information and publicly available information.
Physical	Ambient noise	Browse Development Area and BTL corridor and surrounds	Woodside has sufficient information on ambient underwater noise in the Browse Development Area and BTL corridor on the basis that the area is offshore and remote from urban or industrial areas, with ambient noise characterised by natural ecological and hydrodynamic processes. In addition, noise monitoring program was implemented from September 2006 to May 2011 by Curtin (2011) which included deployment of sea noise loggers at 23 sites around Scott Reef. This programme was specifically designed to characterise the noise environment within and adjacent to the reef during ambient conditions and during a drilling programme within the Browse Development Area in 2008. Other than underwater noise emissions associated with the NRC facility, and shipping routes near the BTL route, local underwater noise emissions via anthropogenic sources are likely limited to occasional vessels.	Literature review of Woodside information and publicly available information.
Ecological	Planktonic communities	Browse Development Area and BTL corridor and surrounds	Three years of data (Brinkman et al. 2009a, 2009b, 2010) have been collected to understand seasonality and ecological drivers of the plankton communities within the Browse Development Area. There is unlikely to have been any significant changes to these processes since the study was undertaken. Consequently, it is determined that this data provides Woodside with a good baseline knowledge of planktonic communities within the Browse Development Area to support impact assessment process. Similarly, it is considered that there is sufficient understanding of planktonic communities within the broader NWMR, including along the BTL corridor from regional studies (Brewer et al. 2007).	Literature review of Woodside information and publicly available information.
Ecological	Epifauna and Infauna	Browse Development Area and BTL corridor and surrounds	The available studies and literature provide a good understanding of the deep water epifauna and infauna communities within the Browse Development area. Given the nature of these communities and the lack of significant disturbances within the deeper waters of the Browse Development Area, it is unlikely that there have been significant changes in these communities since the studies were carried out. Consequently, these studies are deemed to provide a good understanding of these ecological values within the Browse Development Area to support the impact assessment process for the project. In addition, such parameters will be used to support the interpretation of the discharge modelling results. It is considered that there is sufficient understanding of epifauna and infauna assemblages along the BTL corridor which are expected to be typical of the offshore waters in the region as described in Williams et al. 2010. However additional information will be gained from the pipeline environmental survey.	Literature review of Woodside information and publicly available information. Implementation of a marine environmental survey of the BTL corridor including characterisation of infauna and epifauna assemblages.
Ecological	Coral	Browse Development Area including Scott Reef, Rowley Shoals	Major changes to coral in the Browse Development Area over recent years are possible due to cyclones and thermal-induced bleaching. As such Woodside will utilise ongoing long-term monitoring and research program (1994-2018), which provides current and historical data, to support existing environmental baseline knowledge. This, together with previous studies undertaken in the area including studies undertaken in relation to the previous Browse Development concepts, provides Woodside with a good understanding of coral communities in the Browse Development Area including Scott Reef. This includes habitat mapping of Scott Reef undertaken by Smith *et al* 2006. In addition, Woodside, in partnership with AIMs continues to undertake long term monitoring of shallow water corals at Scott Reef and Rowley Shoals (Gilmour et al 2018). Given the proposed water depths along the BTL it is not anticipated that any coral communities will be encountered. Nevertheless, the BTL environmental survey will investigate benthic habitats at selected sample locations along the trunkline route. Such locations have been chosen based on a number of criteria outlined in **Section 3.7.6**. This does not apply in the area near the NRC tie in point, where Woodside has a good understanding of coral. It also does not apply in the area adjacent to the Browse Development Area where studies have been undertaken.	Literature review of Woodside information and publicly available information. Preparation of habitat maps with demonstrated ground truthing for areas where proposed infrastructure will be installed on the seabed within the Browse Development Area. Implementation of a marine environmental survey of the BTL corridor including benthic habitat characterisation (noting that due to water depths, it is considered highly unlikely that hard coral communities will occur along the BTL corridor).
Ecological	Seagrass	Browse Development Area including Scott Reef, Rowley Shoals	Given the previous and ongoing benthic habitat studies undertaken in the area, Woodside has a good understanding of the status of seagrass communities within Scott Reef area. Given the proposed water depths along the BTL it is not anticipated that any seagrass communities will be encountered. Nevertheless, the BTL environmental survey will investigate benthic habitats at selected sample locations along the trunkline route. Such locations have been chosen based on a number of criteria outlined in **Section 3.7.6**. This does not apply in the area near the NRC tie in point, where Woodside has a good understanding of seagrass. It also does not apply in the area adjacent to the Browse Development Area where studies have been undertaken.	Literature review of Woodside information and publicly available information. Preparation of habitat maps with demonstrated ground truthing for areas where proposed infrastructure will be installed on the seabed within the Browse Development Area. Implementation of a marine environmental survey of the BTL corridor including benthic habitat characterisation (noting that due to water depths, it is considered highly unlikely that seagrass will occur along the BTL corridor).

Receptor Group	Receptor	Key Areas of Consideration	Assessment of Current Level of Understanding and information gaps	Environmental Studies Workplan
Ecological	Macroalgae	Browse Development Area including Scott Reef, Rowley Shoals	Woodside has a good understanding of macroalgae in the Browse Development Area including Scott Reef via previous studies undertaken in the area including studies undertaken in relation to the previous Browse Development concepts (e.g. Gardline 2009). Sufficient information on macroalgae at Rowley shoals exists in the literature (e.g. Gilmour et al. 2018) to support the impact assessment for the project. There is currently a lack of specific information on macroalgae along the BTL route although it is considered unlikely that they will would occur due to the water depth. This does not apply in the area near the NRC tie in point, where Woodside has a good understanding of macroalgae. It also does not apply in the area adjacent to the Browse Development Area where studies have been undertaken.	Literature review of Woodside information and publicly available information. Preparation of habitat maps with demonstrated ground truthing for areas where proposed infrastructure will be installed on the seabed within the Browse Development Area. Implementation of a marine environmental survey of the BTL corridor including benthic habitat characterisation (noting that due to water depths, it is considered highly unlikely that macroalgae will occur along the BTL corridor).
Ecological	Seabirds and migratory shorebirds	Scott Reef, Rowley Shoals	The East Asian-Australasian Flyway (EAAF) is of most relevance to the Project Area and associated shorebird and seabird species. This flyway extends from north-eastern Asia and western Alaska in the north, to Australia and New Zealand in the south, encompassing 23 countries (Hansen et al., 2016). There are 37 species of shorebird and seabird which annually migrate to Australia using the EAAF (Hansen et al., 2016). Seabirds within the North West Marine Region (NWMR) consist of tropical and sub-tropical breeding species and non-breeding migratory species. Recent surveys around Ashmore Reef, Seringapatam Reef, Scott Reef and the wider Browse Basin region identified 26 species of seabird, including the brown booby, Abbott's booby, streaked shearwater and lesser frigatebird (Jenner et al., 2009; Milton, 1999; Smith et al., 2004; Jenner et al. 2009; WAM 2009). A number of offshore islands within the NWMR support breeding colonies of seabirds, with the islands at Ashmore Reef are regarded as supporting some of the most important seabird breeding colonies on the NWS. Due to the large geographical range of seabirds, there is potential that most species occurring within the wider NWMR may occur transitionally within the Project Area. An initial PMST search identified two species of threatened seabird as potentially occurring within the Development Area; the Abbott's booby (Endangered, Marine) and Australian lesser noddy (Vulnerable, Marine). In addition, six other species of listed marine and/or migratory seabird species were identified as having the potential to occur within and/or interact with the Proposed Action. As Scott Reef is the only emergent land mass within the immediate vicinity of the Development Area it may serve to provide nesting and / or roosting for migratory seabirds along the flyway. However, Seabirds around Scott Reef are predominately associated with Sandy Islet and occur in relatively small numbers in comparison to other key breeding and roosting sites within the region. Smith et al. (2004) recorded little tern (500 individuals), brown booby (6), ruddy turnstone (50), Australian lesser noddy (200) and the common noddy (30) during a survey at Scott Reef in 2003. More recent surveys at Scott Reef observed greater numbers of birds during spring than winter (Jenner et al., 2009), with seabird typically roosting on Sandy Islet at night and presumably foraging within the nearby and offshore waters during the day. Migratory shorebirds are occasionally observed in very low numbers at Scott Reef, with Sandy Islet potentially acting as a stopping point during the migration between the Northern Hemisphere and Australia (Commonwealth of Australia, 2008). Despite the fact that seabirds and shorebirds are regularly observed at Scott Reef, given the size of the available landmass at Sandy Islet, it is unlikely to be a critical location or support large numbers of migratory birds. Based on the available studies and literature, Woodside has a good understanding of the seabirds and shorebirds that may occur within the Development Area to support the impact assessment process for the project.	Literature review of Woodside information and publicly available information including a review of applicable State and Commonwealth guidance and conservation plans Protected Matters Search and SPRAT profile review of relevant species.
Ecological	Fish	Browse Development Area including Scott Reef, Rowley Shoals, BTL Corridor	Woodside has a good understanding of fish that may occur at Scott Reef and Rowley Shoals via available literature and previous studies undertaken in the area (e.g. DEC 2007). In addition, Woodside, in partnership with AIMs continues to undertake long term monitoring of shallow water fish communities at Scott Reef. Fish that may occur along the BTL corridor are expected to be reflective of the open waters of the North-west Marine Region for which significant information is available in existing literature. With respect to the protected whale shark, Woodside previously studied migration patterns using tagging and tracking (Meekan *et al* 2010) with this information considered sufficient to inform the impact assessment.	Literature review of Woodside information and publicly available information including a review of applicable State and Commonwealth guidance and conservation plans Protected Matters Search and SPRAT profile review of relevant species. Implementation of a marine environmental survey of the BTL corridor including the opportunist recording of marine megafauna.
Ecological	Marine mammals	Browse Development Area including Scott Reef, BTL Corridor	A large number of surveys have been undertaken on marine mammals in relation to previous Browse Development concepts. These have included habitat association surveys (Sutton et al., 2018), long term sea noise logger deployment (McCauley 2011), aerial and vessel surveys (Jenner & Jenner 2009a, 2009b, RPS 2010a, 2010b, 2010c, 2011a, 2011b, 2011c) and satellite tagging (Double et al. 2010, 2012, 2014). An additional study was recently commissioned by Woodside in Q4 2017 to review the current state of knowledge for blue whales which may be affected by the Proposed Action, including reviewing current understanding of migration, foraging, distribution, and breeding behaviours, and identifying major knowledge gaps. Pygmy blue whales are recognised as a key species for consideration in the EIS/ERD. The Conservation Management Plan for Blue Whales (Commonwealth of Australia, 2015) documents a possible foraging area within the vicinity of Scott Reef which has been defined as a BIA for foraging. Unlike the Perth Canyon which is recognised as a seasonally important foraging area for pygmy blue whales, as shown by both visual and acoustic surveys (Balcazar et al., 2015; McCauley et al., 2000, 2004), there is no observational or recorded evidence to confirm Scott Reef is a feeding ground for this species. Rather, pygmy blue whales have been encountered	Literature review of Woodside information, including the recently completed study on the current state of knowledge for blue whales, and publicly available information including a review of applicable State and Commonwealth guidance and conservation plans Protected Matters Search and SPRAT profile review of relevant species. No further marine mammal specific surveys are considered necessary to inform the impact assessment. However, the implementation of a marine environmental survey of the BTL corridor will include the opportunist recording of marine mega fauna.

Receptor Group	Receptor	Key Areas of Consideration	Assessment of Current Level of Understanding and information gaps	Environmental Studies Workplan
			during periods of elevated biomass at Scott Reef, and feeding has not been directly observed (Sutton et al., 2018). It is likely that pygmy blue whales feed opportunistically while migrating, however, Scott Reef is unlikely to represent critical habitat for pygmy blue whales. A literature review identified that there is no evidence of population increases in pygmy blue whales and as such Woodside will primarily rely on historical Woodside-funded datasets (~3 years collection period) and other recent non-Woodside datasets to support existing environmental baseline knowledge. Given potential for opportunistic foraging at Scott Reef, Woodside will describe Scott Reef and the surrounding area as a potential area of importance for the sub-species, including for opportunistic feeding, and undertake assessments of impacts and risk to PBW in this context. A literature review undertaken by WAMSI in 2018 highlights that only a small number of humpback whales utilise the Browse Development Area. As such, Woodside will primarily rely on historical Woodside-funded datasets (~3 years collection period) and other recent non-Woodside datasets to support existing environmental baseline knowledge for humpback whales.	
Ecological	Marine reptiles (turtles)	Browse Development Area including Scott Reef	Woodside has a good understanding with respect to the presence and behaviour of marine turtles in the Development Area. Sandy Islet, a part of Scott Reef, is a known nesting site for green turtles, with a number of long-term studies, funded by Woodside, undertaken to establish a baseline of turtle nesting activity (including breeding, internesting and nesting behaviours) at Scott Reef. A total of 435 nesting green turtles were tagged at Sandy Islet over seven surveys undertaken during 2006, 2008 and 2009 (Guinea, 2009), with the peak breeding season observed to be from late November to February. Nesting turtles have been observed to utilise the entire available area of Sandy Islet for nesting, with seasonal variation recorded in the areas used. In terms of internesting habitat, the studies demonstrated that two areas of sandy substrate located to the south of Sandy Islet were identified as a preferred internesting area for the green turtles at Sandy Islet. Tracking of 12 green turtles was undertaken at Sandy Islet in 2010 (Guinea, 2011). These turtles were found to re-nest at Sandy Islet up to five times with an average internesting interval of 10 days. Internesting habitat for these individuals ranged up to 14 km out from the Sandy Islet (Guinea, 2011). Following nesting, these individuals were found to disperse from Sandy Islet toward the WA mainland via two distinct post-nesting migration pathways; travelling east and north toward the Bonaparte Archipelago and then north along the coast to the NT or travelling south to Cape Leveque and then south along the coast to the De Grey River in the Pilbara (Guinea, 2011). It should be noted that while the green turtles at Scott Reef and Browse Island represent a distinct genetic stock, the relatively small available nesting area on Sandy Islet ensures that this location is likely to represent a marginal nesting habitat for the broader population of green turtles within the region, with more significant rookeries located at the Lacepede Islands and Ashmore Reef (both noted as nesting and internesting BIAs for green turtles). The turtle studies undertaken at Scott Reef have provided Woodside with a comprehensive understanding of the nesting carrying capacity of Scott Reef, as well as the population dynamics, preferential nesting and internesting behaviours of marine turtles within the proposed Browse Development Area. The inter-annual nesting population of green turtles at Sandy Islet varies greatly (by at least an order of magnitude) and it is known that a significant proportion of the Scott Reef/ Browse Island green turtle meta-population nest at Sandy Islet. Given the large variability in inter-annual turtle numbers, additional data collection is unlikely to add to this knowledge base.	Literature review of Woodside information and publicly available information including a review of applicable State and Commonwealth guidance and conservation plans. Protected Matters Search and SPRAT profile review of relevant species. No further marine reptile specific surveys are considered necessary to inform the impact assessment. However, the implementation of a marine environmental survey of the BTL corridor will include the opportunist recording of marine mega fauna.
Ecological	Marine reptiles (Sea snakes)	Browse Development Area including Scott Reef	Udyawer et al. (2016) has recently analysed data collected from 2290 Baited Remote Underwater Video Stations (BRUVS) between 1999 and 2016 to better define the range and distribution of sea snake families in the NWMR and to produce predictive models to assess the likelihood of occurrence for major families of sea snakes. From this data, 582 sea snakes were recorded with the highest rates of sea snake sightings observed in the Northern Oceanic Shoals. The majority of sea snakes were of genus Aipysurus (63%) followed by Hydrophis (12%) and Emydocephalus (11%) (Udyawer et al., 2016). Probability of occurrence maps based on available habitats and other environmental parameters indicate that Scott Reef and other remote reef systems within the Northern Oceanic Shoals, as well as mid-shelf shoal habitat along the Kimberley and Pilbara coasts were likely ideal habitat for two IUCN and DoEE listed critically endangered sea snake species, the short-nosed sea snake and the leaf-scaled sea snake (Udyawer et al., 2016, and available at: https://vinayudyawer.github.io/SeaSnake-NicheModels/ModelMap.html). Historically these two species were only recognised as occurring at Ashmore and Hibernia reefs (Cogger, 2014; Guinea, and Whiting, 2005; Storr et al., 2002), although they have not been observed in these locations since 2001 despite considerable effort between 2005 and 2013 (Guinea, 2013). These species have also not been recorded at Scott Reef. Preliminary Protected Matters Searches have identified the short-nosed sea snake as potentially occurring within the Project Area, however, did not identify occurrence of the leaf-scaled sea snake. Recent genetic analysis and field surveys have provided further evidence that these threatened species are more widely distributed than previously thought (D'Anastasi et al., 2016; Sanders et al., 2015). Sanders et al. (2015) found significant molecular and morphological variation between specimens of short-nosed and leaf-scaled sea snakes collected at offshore locations and those collected in coastal areas which were previously considered vagrant. The study indicates specimens of short-nosed seasnakes collected on Barrow Island in 2010 and leaf-scaled seasnakes collected in Exmouth Gulf in 2004 and Broome in 2012 were from distinct coastal breeding populations of sea snakes (Sanders et al., 2015). D'Anastasi et al. (2016) confirmed a wider distribution for these species, providing live records of the short-nosed and leaf-scaled sea snakes outside of Ashmore and Hibernia. The study, which conducted intensive field surveys, assessed previous survey and	Literature review of Woodside information and publicly available information including a review of applicable State and Commonwealth guidance and conservation plans. Protected Matters Search and SPRAT profile review of relevant species. No further marine reptile specific surveys are considered necessary to inform the impact assessment. However, the implementation of a marine environmental survey of the BTL corridor will include the opportunist recording of marine mega fauna and sea snakes.

Receptor Group	Receptor	Key Areas of Consideration	Assessment of Current Level of Understanding and information gaps	Environmental Studies Workplan
			habitat data and molecular genetics data to resolve gaps regarding these two species' distributions, abundances, habitat requirements and conservation statuses in coastal WA, observed sixteen leaf-scaled sea snakes within Shark Bay and seven short-nosed sea snakes within Exmouth Gulf (D'Anastasi et al., 2016). These studies significantly increase the known geographic range of these threatened species, as well as expands their preferred habitat to include seagrass meadows, and are significant given the critically endangered conservation statuses of these species are based off the understanding that their range is restricted to Ashmore and Hibernia (i.e. < 10 km^2). Comprehensive surveys of sea snakes at Scott Reef were undertaken in February, September and November in 2006 (URS, 2007; URS Australia Pty Ltd, 2006) did not observe these two threatened species, however, recorded similar abundances of sea snakes as observed on Hibernia and Cartier Island during the same year. The abundance of sea snakes was found to be dependent on habitat type and ranged between 0 to 2 individuals per hectare. The majority of sea snakes recorded were olive sea snakes and turtle-headed seasnakes, with other species including the dusky sea snake, Dubois's sea snake, horned sea snake, and slender-neck sea snake (Guinea 2013). Sea snakes that were recorded were most common in the more complex reef habitats, although no key sites for juveniles or adults were identified at Scott Reef. No seasonal peaks were detected indicating the majority of individuals were likely residential. Based on the available studies and literature, Woodside has sufficient information on sea snakes that may occur within the Development Area, and specifically within the area of Scott Reef to support the impact assessment process for the project.	
Ecological	Key Ecological Features (KEFs)	Relevant KEFS: • Continental slope demersal fish communities • Seringapatam Reef and Commonwealth waters in the Scott Reef complex • Ancient coastline at 125 m depth contour • Mermaid Reef and Commonwealth waters surrounding Rowley Shoals.	Sufficient information exists on the relevant KEFs for the purpose of impact assessment within the North West Marine Bioregional Plan (Commonwealth of Australia 2012). However additional information will be gained from the pipeline environmental survey.	Literature review of Woodside information and publicly available information. Implementation of a marine environmental survey of the BTL corridor including the benthic habitat survey, sediment sampling and water quality sampling within each intersected KEF.
Ecological	Australian marine parks	Relevant Australian marine parks: • Kimberley Marine Park • Argo-Rowley Terrace Marine Park • Mermaid Reef Marine Park (not intersected)	Sufficient information exists on the relevant Australian marine parks for the purpose of impact assessment within the North-west Marine Parks Network Management Plan 2018 (Director of National Parks 2018). However additional information will be gained from the pipeline environmental survey.	Literature review of Woodside information and publicly available information. Implementation of a marine environmental survey of the BTL corridor including the benthic habitat survey, sediment sampling and water quality sampling within each intersected Australian marine park.
Ecological	State marine parks and reserves	Relevant state marine parks and reserves: • Rowley Shoals	Sufficient information exists on the relevant state marine parks and reserves for the purpose of impact assessment (e.g. DEC 2007).	Literature review of Woodside information and publicly available information.

Receptor Group	Receptor	Key Areas of Consideration	Assessment of Current Level of Understanding and information gaps	Environmental Studies Workplan
		Marine Park (not intersected) • Scott Reef Nature Reserve		
Socio-Economic	Commonwealth managed fisheries	Relevant Commonwealth managed fisheries including: • North West Slope Trawl Fishery (NWSTF) • Western Tuna and Billfish Fishery • Southern Bluefin Tuna Fishery • Western Skipjack Tuna Fishery.	Woodside has sufficient information on the relevant Commonwealth managed fisheries (Patterson et al. 2018) for the purpose of impact assessment via work undertaken on the previously proposed Browse development concepts and ongoing stakeholder consultation.	Literature review of Woodside information and publicly available information. Ongoing stakeholder consultation.
Socio-Economic	State managed fisheries	Relevant State managed fisheries including: • Northern Demersal Scalefish Managed Fishery (NDSF) • Mackerel Managed Fishery • Western Australia North Coast Shark Fishery (WANCSF) • Onslow Prawn Managed Fishery • Abalone Fishery • South west Coast Salmon • Pilbara Fish Trawl and Trap Fishery • Specimen	Woodside has sufficient information on the relevant State managed fisheries (Gaughan et al. 2018) for the purpose of impact assessment via work undertaken on the previously proposed Browse development concepts and ongoing stakeholder consultation.	Literature review of Woodside information and publicly available information. Ongoing stakeholder consultation.

Socio-Economic	Tourism and recreation	Scott Reef, Rowley Shoals	Sufficient information exists on the use of Scott Reef and Rowley Shoals for tourism and recreation purposes for the purpose of impact assessment.	Literature review of Woodside information and publicly available information. Ongoing stakeholder consultation.
Socio-Economic	Shipping	Browse Development Area, BTL Corridor	Sufficient information exists on the use of the Project area and surrounds for shipping for the purpose of impact assessment.	Literature review of Woodside information and publicly available information. Ongoing stakeholder consultation.
Socio-Economic	Industry	Regional	Sufficient information exists on industry in the region including petroleum exploration and production for the purpose of impact assessment.	Literature review of Woodside information and publicly available information. Ongoing stakeholder consultation.
Socio-Economic	Indigenous heritage	Scott Reef, Dampier Archipelago (including Burrup Peninsula) National Heritage place	Sufficient information exists on indigenous heritage (Traditional Indonesian fishers) in the water surrounding Scott Reef for the purpose of impact assessment. Woodside will point to and provide context for the assessment of the potential impacts of the North West Shelf Project Extension Proposal (EPBC 2018/8335) on values specifically related to the National Heritage listing on the Burrup Peninsula.	Literature review of Woodside information and publicly available information. The assessment documentation must provide details of any potential indirect impacts of the proposed action on the (Indigenous rock art) values of the Dampier Archipelago (including the Burrup Peninsula) National Heritage Place, and the extent to which these values may be impacted by the proposed action following any planned mitigations.
Socio-Economic	Maritime archaeology	Browse Development Area, BTL Corridor	Sufficient information exists on maritime archaeology including known ship wrecks in the Project area for the purpose of impact assessment.	Literature review of Woodside information and publicly available information.

3.7.6 Scope of Technical Studies informing Existing Environment

The following technical studies will be undertaken to inform the existing environment description. It should also be noted that Woodside is committed to the continuation of the long-term monitoring at Scott Reef and the Rowley Shoals undertaken in conjunction with the Commonwealth research agency, the Australian Institute of Marine Science (AIMS).

Environmental Survey of BTL Corridor

The objectives of this study are to:

- confirm the environmental characteristics (physical and biological attributes) of the seabed along the BTL route which will include identification and semi qualitative descriptions of seabed habitat types, infauna and epifauna and their general distribution
- determine the baseline condition and physico-chemical composition of seabed sediments and water quality at selected locations along the BTL corridor
- document presence of marine mega fauna sighted opportunistically along the BTL corridor.

The data and information (including habitat mapping) from the environmental survey will be utilised to describe the existing environment and baseline conditions along the BTL route and to inform a regional understanding of marine environmental values through which the BTL traverses. The determination of the baseline environmental values at selected locations of the BTL route will be used as part of the environmental impact and risk assessment process of the EIS/ERD to determine the impacts (if any) to the receiving environment from the installation and physical presence of the BTL.

A reconnaissance survey of the BTL corridor (geophysical) has been undertaken and has been used to identify sampling locations along the BTL corridor. The sampling locations have been selected to characterise the marine environment in proximity to the proposed BTL, with consideration given to regional environmental sensitivities and key ecological features.

At each of the sampling locations the following environmental parameters will be collected:

- water, seabed sediment, infauna and epifauna
- benthic habitat imagery for habitat classification and description (semi-quantitative analysis of seabed imagery (High Resolution video and stills)
- opportunist sightings of marine mega fauna.

3.8 Impacts and Risk

3.8.1 Overview

The purpose of this chapter is to present the environmental impact and risk assessment undertaken including the source activities, the magnitude and extent of potential impacts, proposed mitigation strategies, environmental objectives and performance criteria.

3.8.2 Format of Chapter

The impact and risk chapter will provide a high-level overview of the sources of each risk and impact aspect as well as the potential receptors groups that may be affected. This will be followed by a detailed description of each relevant impact and risk, proposed mitigation measures and an overall conclusion on the predicted environmental outcome, in relation to the aspect, and with reference to the relevant MNES significance criteria and/or WA EPA Environmental Objective.

The description of each aspect will be set out in a format broadly similar to the following outline:

1. Aspect (e.g. Noise Emissions)
   1.1. Environmental Objective
   1.2. Policy and Guidance
   1.3. Source Activities
   1.4. Receptor and Receptor Sensitivity
   1.5. Environmental Impact
   1.6. Environmental Risk
   1.7. Cumulative Impacts
   1.8. Mitigation and Management
   1.9. Other Considerations
   1.10. Performance Criteria
   1.11. Impact and Risk Assessment Summary and Acceptability Assessment

3.8.3 Impact and Risk Assessment Requirements

This section will include:

- description of all relevant potential impacts and risks of the action
- a detailed assessment of the nature and extent of the potential short term and long term relevant impacts, including on MNES and WA EPA Environmental Factors including the natural Heritage values of 'Scott Reef and surrounds'
- a statement whether any relevant potential impacts are likely to be unknown, unpredictable or irreversible
- analysis of the significance of the relevant potential impacts and risks
- any technical data, any sources of authority, and other information used or needed to make a detailed assessment of the relevant potential impacts. Reliability of forecasts and predictions, confidence limits and margins of error will be indicated as appropriate.

In discussing potential impacts, particular emphasis is to be given to providing details on the potential impacts to the receiving environment's unique flora and fauna, as identified and to any protected areas in the vicinity.

In particular the EIS/ERD will address the following.

General impacts

The following encompasses a list of general impact considerations:

- discuss the effects of the overall action on the functioning of the marine environment, including effects to the marine environment surrounding the proposed development
- identify the source of potential impacts, e.g. ship-movements, artificial lighting, noise
- discuss potential impacts which may arise through the transportation, storage and use of dangerous goods (if any), fuels and chemicals, such as accidental spills
- consider the application of a waste management hierarchy (e.g. reduce, reuse, recycle, treat, dispose) and potential impacts caused by the need for waste disposal and management of emissions, refuse, effluent and hazardous waste (if any)

- in discussing potential impacts, consider how the interaction of extreme environmental events and any related safety response may impact on the environment
- consider potential impacts throughout the life of the proposed Browse to NWS Project – from construction, commissioning, IMR activities and operations through to decommissioning.

Physical and biodiversity impacts

The following encompasses a list of physical and biodiversity impact considerations:

- consider potential impacts to the sea floor through anchoring and direct placement, sediment disturbance, as well as any impacts of removal. The zone of likely seabed disturbance will be identified.
- consider potential impacts to fauna and flora species, including rare, threatened, or otherwise valuable flora and fauna, communities (particularly listed threatened species and communities, listed marine species including whales and other cetaceans and listed migratory species). In assessing impacts, consideration will be given to factors such as population composition and density including changes to communities, breeding success, habitat, or disturbances to migration or migratory patterns and other wildlife movements.
- consider potential impacts to the recovery of species where a species recovery plan is in place including factors called up in the requirements of the relevant recovery plans.
- consider potential impacts, if any, on and habitat, conservation areas, biological important areas, key ecological features and protected areas (including Australian Marine Parks), and in particular Scott Reef and surrounds.
- consider potential impacts arising from the introduction and/or spread of exotic pest species.

Impacts of emissions to air and water

The following encompasses a list of emissions to air and water impact considerations:

- discuss the potential impact of solid, liquid and gaseous emissions and waste produced by the operation, including greenhouse gas emissions.
- refer to the NWS Extension assessment being progressed by the NWS JV under the EP Act (Assessment number 2186) and EPBC Act (EPBC 2018/8335) in relation to potential impacts resulting from the processing of Browse gas by a third party on the Burrup Peninsula.
- include a discussion on the eventual fate of the waste.
- provide a full evaluation of PW, CW and hydrotest discharges including anticipated composition of discharge, modelling of the mixing zones and discussion on the potential impacts of discharge, including the spatial and temporal impacts of discharged PW and hydrotest fluid on marine fauna and key benthic ecological receptors (e.g. corals, seagrass, magroalgae), which may provide habitat and food resources for listed threatened species (e.g. marine turtles).
- consider the potential impacts of water clarity, salinity and temperature changes with specific reference to stratification of the water column.
- discuss potential impacts related to the discharge of sewage, sullage and other production related discharges.
- discuss impacts of potential spillage of hydrocarbons related to construction, production, storage and shipping. Modelling of spills will take into account seasonal variations throughout the year. Modelling will also take into account proximity to sensitive marine areas, in particular Scott Reef and surrounds. The evaluation of the potential impacts of oil spills is to be carried out using a thorough risk-assessment methodology.

Socio-economic and cultural impacts

Discussion of the potential socio-economic and cultural impacts of the proposed Browse to NWS Project as required. This will include a description and discussion of potential impacts (both positive and negative):

- caused by any short, medium and long-term changes, interruption, alteration or curtailment of activities and uses of the area due to the Proposed Action, including changes affecting traditional uses, recreational uses, conservation and tourism
- on sites of historical or cultural significance
- on existing industry and commerce
- to employees in terms of workplace health and safety
- on shipping and any potential traffic hazards
- on visual and aesthetic values, impacts to tourism and access for conservation purposes
- to historic shipwrecks in the area, including potential impacts on, as yet, unknown shipwrecks or those in unsurveyed areas.

Cumulative Impacts

Cumulative impacts will also be identified and addressed. Cumulative impacts from the proposed Browse to NWS Project may occur in two ways:

- Aspect-based – Cumulative or combination effects from concurrent and/or sequential activities associated with the proposed Browse to NWS project, and other activities/projects resulting in the same aspects as those identified for the proposed Browse to NWS Project
- Receptor-based – Cumulative or combination effects on a receptor, both from multiple aspects of the proposed Browse to NWS Project and similar/multiple aspects resulting from other activities/projects.

The aspect based cumulative impacts will be presented within each aspects chapter (e.g. noise emissions).

Aspect-based cumulative impacts resulting from concurrent activities with the same aspect (e.g. concurrent underwater noise emissions from different project activities) will be assessed as part of the impact and risk assessment for each aspect. Where appropriate, modelling studies will take into account the multiple sources to inform a robust impact and risk assessment of each aspect on each relevant receptor.

The assessment of aspect-based cumulative impacts resulting from activities/projects not associated with the proposed Browse to NWS project will include assessment of reasonably foreseeable activities and projects. These activities may include:

- Woodside and other operator exploration activities
- Other oil and gas developments (including those known potential future expansions or developments in the vicinity)
- Commonwealth and State Managed Fisheries
- Other users such as tourism and recreation, traditional fishing and commercial fishing.

Other activities/project considered in the cumulative impact assessment will be selected based on the type of activity, spatial scale and time scale. Activities will only be taken into account if they:

- Have not already been taken into consideration previously in the impact assessment (i.e. as part of baseline conditions)

- Have aspects that may cause impacts on the same receptors as the proposed Browse to NWS Project
- Activities that exist or have a high degree of certainty of proceeding in the future, such as those with construction activities underway or for which approvals and budget have been obtained
- Activities for which sufficient information is available to conduct a qualitative assessment to a reasonable standard.

Once each potential cumulative impact from other activities/projects is identified an assessment of the significance of the cumulative impact will be undertaken and documented. Note that due to the inherent difficulties associated with accessing data associated with other proposed developments, the evaluation will be based on a qualitative assessment.

Receptor-based cumulative impacts resulting from concurrent activities generating common pressures (e.g. sequential drilling over the project and its light emissions) will be addressed in the overall conclusions section which will include a qualitative assessment of the cumulative impacts on each key receptor and assess impacts on a more holistic, whole-ecosystem level, considering the potential cumulative impacts of the proposed project, and any existing and future concurrent activities, on the existing environment.

3.8.4 Impact and Risk Assessment Process

An environmental risk and impact assessment will be undertaken in accordance with Woodside's Environment Impact Assessment Guideline. This guideline and associated Environment Impact Assessment Guidance Tool and Environment Risk Assessment Guidance Tool support the implementation of impact assessments and set out the broad principles and high-level steps for assessing environmental impacts across the lifecycle of Woodside's activities.

Within this process, a distinction is made between an 'impact' and a 'risk' as follows:

Environmental Impact: An expected change to the environment, whether adverse or beneficial, wholly or partially resulting from the planned and routine project activities including mitigation measures (e.g. routine liquid discharges).

Environmental Risk: A change to the environment resulting from an unplanned event or incident (e.g. oil spill resulting from vessel collision).

The environmental impact assessment approach undertaken will include the following steps:

1. Identification of project **aspects** (i.e. results of planned or unplanned project activities that have the potential to impact on the environment).
2. Identification of the **receptors** (i.e. physical, biological, cultural or human elements of the environment that may be impacted by project aspects).
3. Assessment of the **receptor sensitivity** (i.e. the sensitivity/vulnerability/importance of the /receptor) as either high, medium or low value.
4. Assessment of the **magnitude** (i.e. no lasting effect, slight, minor, moderate, major or catastrophic) of the credible environmental impacts from each aspect based on the extent, duration, frequency and scale.
5. Assigning an **impact significance level** to each environmental impact based on the receptor sensitivity and the magnitude of the impact.
6. Assigning an **environment risk consequence** to each environmental risk based on the receptor sensitivity and magnitude of the impact; and the likelihood of occurrence.
7. Utilising the impact significant level and environmental risk consequence to undertake an assessment of the Proposed Action against the EPBC Act Significant Impacts Criteria, Western

Australian EPA Objectives and other policy instruments including Australian Marine Park management plans and species recovery plans.

The following impact significant levels may be assigned for the environmental impacts:

- Catastrophic (A) - Applicable limits or standards are substantially exceeded and/ or catastrophic or major magnitude impacts are expected to receptors of medium/ high or high sensitivity respectively.
- Major (B) - Applicable limits or standards are exceeded and/ or moderate, major or catastrophic magnitude impacts are expected to occur to receptors of high, medium or low sensitivity respectively.
- Moderate (C) - Impacts are close to applicable limits or standards, or within standards but with potential for occasional exceedance. Minor, moderate or major magnitude impacts are predicted to occur to receptors of high, medium or low sensitivity respectively.
- Minor (D) - Impact magnitude is within applicable standards but is considered to have significance. Slight, minor or moderate impacts are predicted to occur to receptors of high, medium or low sensitivity respectively.
- Slight (E) - The receptor will experience a noticeable effect, but the impact magnitude is sufficiently small and well within applicable standards, and/or the receptor is of low value.
- Negligible (F) - The receptor will essentially not be affected.

Environment risk consequences are determined slightly differently than impact significant levels due to the requirement to consider the likelihood that the unplanned event or incident occurs.

The likelihood of a risk event occurring can be considered:

- Remote (0) – unheard of in the industry
- Highly unlikely (1) – has occurred once or twice in the industry
- Unlikely (2) – has occurred many times in the industry by not at Woodside
- Possible (3) – may possible occur
- Likely (4) – is likely to occur
- Highly likely (5) – is expected to occur

The following risk levels may be assigned for the environmental risks:

- Severe
- Very High
- High
- Moderate
- Low.

The outcomes of the preliminary environment impact assessment of planned activities are shown in **Table 7**. The outcomes of the preliminary assessment in relation to environmental risks from unplanned incidents or risk events are shown in **Table 8**. The preliminary impact and risk assessments were undertaken as part of the EPBC Act and EP Act referral process and have been provided to provide context to the workplan detailed in this EISG/ESD. It should be noted that the impact and risk assessment outcomes may change as further information comes available and more detailed analysis and evaluation is undertaken in preparing the EIS/ERD. Further change may also occur as a result of considering any feedback received from Stakeholders on the draft EIS/ERD.

3.8.5 Source, Aspect and Receptor Scoping

Preliminary scoping of the relationship between the proposed activities and the aspects has been undertaken and is presented in **Table 9.**

Each of these relationships will be considered when assessing the impact (from planned routine and non-routine events) and risk (from unplanned events) of the aspect. Scoping of the receptors that could be conceivably (in consideration of the location of the receptors) be affected by the potential impacts and risks has been undertaken and is presented in **Table 10.**

.

Table 7 Preliminary Environmental Impact Assessment (Woodside 2018)

Ref.	Aspect	Source/Activity	Receptor Sensitivity Level	Predicted Impact	Impact Significance Level
IMP-1	Underwater noise emissions	• Drilling and completion of wells including vertical seismic profiling (VSP) • Installation of SURF, BTL and inter-field spur line • Suction piling for mooring installation (FPSO and MODU) • Pile Driving as a contingent planned activity • MODU dynamic positioning • Wellhead operations • Routine FPSO operations (thrusters, compressors, pumps) • Condensate tanker operations • Construction and support vessel operations • Inspection, maintenance and repair activities including ROVs • Routine helicopter operations • Decommissioning activities.	High value species (e.g. cetaceans)	Slight impact (behavioural, avoidance) on high value species on a near-field scale for duration of activities.	D – Minor
IMP-2a	Light emissions – MODU and FPSO	• Routine FPSO operations • Intermittent FPSO flaring • MODU operations.	High value species (e.g. marine turtles)	Slight impact (attraction/repulsion, disorientation) on high value species on a near-field scale for duration of the activities.	D – Minor
IMP-2b	Light emissions - Vessels	• Construction and support vessel operations.	High value species (e.g. seabirds and migratory birds)	Slight impact (attraction/repulsion, disorientation) on high value species on a near-field scale for duration of the activities.	D – Minor
IMP-3a	Physical presence of infrastructure during construction	• Seabed disturbance from seabed preparation, MODU anchors and FPSO anchoring and mooring lines.	Medium value habitat (not impacting Scott Reef or Rowley Shoals)	Slight impact (due to short duration) to medium value habitat on a localised scale during construction activities.	E – Slight
IMP-3b	Physical presence of infrastructure during operations	• Seabed disturbance from the installation of infrastructure (wells, SURF, BTL and inter-field spur line) • Construction and support vessel operations.	Medium value habitat (not impacting Scott Reef or Rowley Shoals)	Slight impact (due to low magnitude) to medium value habitat on a localised scale for the duration of the activities.	E - Slight
IMP-4a	Gaseous emissions - direct air emissions	• Power generation on construction vessels, support vessels, FPSO facilities • Condensate tankers • Flaring	Low value (remote location with limited sensitive receivers)	Slight reduction in air quality on a local scale for the duration of the activities.	F - Negligible

Ref.	Aspect	Source/Activity	Receptor Sensitivity Level	Predicted Impact	Impact Significance Level
		• Venting • PW degassing • Gas export compression units • AGRU - venting of hydrocarbons in waste Acid gas stream			
IMP-4b	Gaseous emissions – indirect air emissions	Woodside will point to and provide context for the assessment of the potential impacts of the North West Shelf Project Extension Proposal (EPBC 2018/8335) on values specifically related to the National Heritage listing on the Burrup Peninsula.			
IMP-4b	Gaseous emissions -GHG	Refer to Section 3.9.			
IMP-5	Treated sewage	• Discharge of sewage and sullage (within regulatory discharge limits) from FPSO, condensate tanker and construction and support vessels.	Medium value (open offshore waters)	Slight impact as a result of near-field nutrient enrichment of surrounding waters in offshore open ocean waters.	E - Slight
IMP-6	Treated PW and NORMs.	• Discharge of PW from the FPSOs to the marine environment (within accepted industry standards limits) • Discharge of formation water from MODU during well clean-up activities • Release of NORMs contained in produced sand and scale (if produced) to marine environment • Discharge of MEG as part of PW (MEG injection on start-up and shutdown) • Discharge of mercury within PW to the marine environment (within accepted industry standards limits)	Medium value (open offshore waters)	Minor impact as a result of near-field contamination to surrounding waters above relevant guidance/ background levels for the duration of the activity.	D – Minor
IMP-7a	Treated utility water	• Oily water drainage from machinery and storage areas discharged to sea (within regulatory discharge limits) from the FPSO facilities, MODU, construction vessels and support vessels • Discharge (within regulatory discharge limits) of water used in power generation (blade washing) on FPSO • Discharge of bilge water (within regulatory discharge limits) from FPSO, MODU, construction vessels and support vessels • Discharge of ballast water including biocides from the FPSO.	Medium value (open offshore waters)	Negligible impact as a result of temporary localised contamination to surrounding waters.	F - Negligible
IMP-7b	Treated utility water – desalination brine	• Discharge of brine from potable water maker on FPSO, MODU, construction vessels and support vessels	Medium value (open offshore waters)	Negligible impact as a result of temporary localised contamination to surrounding waters.	F - Negligible
IMP-8	Cooling water	• Discharge of cooling water from the FPSO facilities.	Medium value (open offshore waters)	Minor, near-field contamination to surrounding waters above relevant guidance/ background levels for the duration of the activity.	D – Minor
IMP-9	Putrescible organic waste	• Disposal of food scraps and other	Medium value (open offshore waters)	Negligible, localised impact to surrounding waters as a result of nutrient enrichment for	F - Negligible

Ref.	Aspect	Source/Activity	Receptor Sensitivity Level	Predicted Impact	Impact Significance Level
		putrescible wastes from offshore facilities.		the duration of the activity.	
IMP-10	Inorganic waste	• Generation and disposal (at a licensed onshore facility) of general inorganic non-hazardous wastes from offshore activities • Generation and disposal at a licensed onshore facility) of hazardous wastes from offshore activities (e.g. tank cleaning waster, contaminated amine, waste, produced sand, mercury waste)	Low (licensed disposal facility)	Negligible localised impacts to a low value environment (licensed disposal facility) for the duration of the activities.	F - Negligible
IMP-12	Drilling cuttings and fluids	• Generation of drill cuttings during drilling and completion activities. • Discharge of cement slurry	Medium value (sparse deep water benthic habitats)	1. Slight, short term decrease in water quality on near field scale. 2. Slight, localised impact on benthic habitat that is permanent.	E - Slight
IMP-13	Subsea control fluid	• Discharge of subsea control fluid during operations of the SURF.	Medium value (open offshore waters)	Negligible impact as a result of contamination to surrounding waters that is temporary and localised which may occur sporadically for the duration of the activities.	F – Negligible
IMP-14	Hydrotest and preservation fluid	• Discharge of hydrotest and preservation fluid from the SURF • Discharge of hydrotest and preservation fluid from the BTL and inter-field spur line.	Medium value (open offshore waters)	Negligible impact as a result of contamination to surrounding waters that is temporary and localised and will occur only once during commissioning.	F – Negligible
IMP-15	Atmospheric Noise	Helicopter movements between mainland and project area.	High value species (e.g. cetaceans)	Slight impact (behavioural, avoidance) on high value species on a near-field scale for duration of activities.	D - Minor

* IMP-11 Hazardous Waste combined with IMP 10 – inorganic waste

Table 8 Preliminary Environmental Risk Assessment (Woodside 2018)

Ref.	Aspect	Risk Event	Receptor Sensitivity Level	Risk Consequences	Risk Consequence Level	Likelihood	Risk Rating
Risk-1	IMS	Vessel (including FPSO) and MODU movements or ballast water exchange leads to the introduction and establishment of IMS	High value habitat (Scott Reef, Rowley Shoals etc)/native species	Moderate, medium term impact to high value habitat/ native species on a regional scale.	B – Major	1 – Highly unlikely	Moderate
Risk-2	Treated PW	Discharge of PW to the marine environment at levels significantly higher than expected levels	High value habitat (Scott Reef)/native species	Minor, short term impact (contamination) to high value habitat (Scott Reef)/native species.	C - Moderate	0 - Remote	Moderate
Risk-3	Utility Water – drain discharges	Unplanned discharge of drain waters potentially containing oil and grease	High value habitat (Scott Reef)/native species	Negligible short term impact (contamination) to high value habitat (Scott Reef)/native species.	E - Slight	1 – Highly unlikely	Low
Risk-4	Cooling water	Cooling water mixing zone significantly larger than predicted resulting in impacts to Scott Reef or high value species	High value habitat (Scott Reef)/native species	Slight short term impact (contamination) to high value habitat (Scott Reef)/native species.	D - Minor	0 - Remote	Low
Risk-5	Non-hazardous inorganic waste	Unplanned discharge of non-hazardous inorganic waste to the marine environment	High value habitat (Scott Reef)/native species	Negligible short term impact (contamination) to high value habitat (Scott Reef)/native species.	E - Slight	1 – Highly unlikely	Low
Risk-6	Hazardous Waste	Unplanned discharge of hazardous waste to the marine environment	High value habitat (Scott Reef)/native species	Slight short term impact (contamination) to high value habitat (Scott Reef)/native species.	D - Minor	2 – Unlikely	Moderate
Risk-7	Drilling cutting and fluids	Distribution and impact of drill cuttings significantly wider than predicted resulting in impacts to Scott Reef	High value habitat (Scott Reef)/native species	Slight short term impact (contamination) to high value habitat/native species.	D - Minor	2 – Unlikely	Moderate
Risk-8	Seabed subsidence	Removal of hydrocarbons from Torosa results in seabed subsidence impacting on the ecological function of Scott Reef	High value habitat (Scott Reef)/native species	Permanent event with negligible impact to high value habitat (Scott Reef)/native species.	E - Slight	1 – Highly unlikely	Low
Risk-9	Hydrocarbon spill	1. Loss of well controls 2. Subsea loss of control 3. Loss of hydrocarbons from topsides 4. Loss of control from substructure (storage of condensate or diesel) 5. Loss of containment from export BTL (gas only) 6. Loss of containment from vessel collision	Multiple high value habitats and high values species	Long term contamination to multiple high value habitats and native species at levels above standards and on a regional scale.	A - Catastrophic	1 – Highly unlikely	High
Risk-10	Vessel interaction with fauna	Vessel collision (including fast crew transfer vessel) with fauna resulting in injury or death to individual	High Value Species	Slight impact (Injury or mortality to single individual) of high value species	C - Moderate	2 – Unlikely	Moderate

3.8.6 Previous studies to assess impacts and risks

Throughout the approvals process of the previous Browse development concepts (JPP and FLNG) various technical studies were undertaken to inform the assessment of the impacts and risks associated with the development concept. These technical studies are detailed in **Table 11**. Many of the potential environmental impacts associated with offshore drilling and completion, installation and operational activities of the previous Development concepts remain unchanged and relevant to the proposed Browse to NWS Project. Similarities between the concepts include the number and locations of wells and subsea tiebacks which have either reduced or remain broadly unchanged. The notable differences are the addition of the inter-field spur line and the BTL.

Due to these similarities, significant work has previously been undertaken with respect to understanding, assessing and mitigating potential environmental impacts and risk. With respect to the environmental aspects, the proposed Browse to NWS Project is expected to lead to the following when compared to the approved FLNG development concept:

- A reduction in the number of offshore facilities (2 x FPSO vs 3 x FLNG). Only one FPSO will be located at Torosa (compared to 2 x FLNG)
- A reduction in the number of development wells from 64 over Development life to a maximum of 49
- A reduction in shipping near Scott Reef as there is no LNG offtake
- A reduction in cooling water discharge
- Approximately the same amount of condensate storage per FPSO and offtake (reduction overall due to 2 x FPSO vs 3 x FLNG)
- Increased produced water (PW) during later field life
- Approximately the same distance between the facilities and Scott Reef
- A reduction in noise sources (fewer offshore facilities and less well drilling, completion and well unload (drilling and completion) activities)
- A reduction in mono ethylene glycol (MEG) injection requirements relating to a change from continuous MEG injection to active heating (noting that MEG injection will still be required for start-up and shutdown)
- A change to MEG discharge within the FPSO PW stream as opposed to recovery on a FLNG facility. This will result in higher MEG concentrations discharged but only at flowline or well restarts as opposed to continuous trace MEG concentrations in the PW stream
- Decreased energy consumption (CO_2) for offshore processing as compared to FLNG based on removal of liquefaction requirements from the proposed offshore development concept. This decrease is partially offset by additional requirement for export compression
- Increased seabed disturbance due to installation of the BTL and the inter-field spur line.

Table 11 Previous studies undertaken to understand the impacts and risks in relation to development of the Browse resource

3.8.7 Summary of Workplan

Woodside has reviewed the previous technical studies in terms of relevance to the proposed Browse to NWS Project. Where emissions (in terms of location, magnitude, frequency and toxicity) are expected to be comparable to previous Development concepts, it is considered that sufficient understanding of the impacts and risks exists. Where significant differences exist to previous studies, new studies will be undertaken to inform the EIS/ERD. An overview of the current level of understanding of the potential impacts and risks as well as the workplan for each aspect is provided in **Table 12**.

Table 12 Impact and Risk Assessment Workplan

ID	Aspect	Key Aim	Assessment of Current Level of Understanding	Workplan
IMP-1	Underwater noise emissions	Understand and assess potential impacts to sensitive receptors (marine fauna) resulting from the generation of underwater noise.	Woodside has a good understanding with respect to the underwater noise generated from the proposed activities via studies undertaken for the previous Browse Development concepts. Understanding of underwater noise from construction activities (e.g VSP, drilling, seabed preparation, vessel movements) is considered sufficiently understood to inform the impact assessment for the EIS/ERD. Underwater noise associated with the physical presence of dynamically positioned MODU/vessel is also considered well understood, however to support the environmental impact assessment of this activity in the EIS/ERD, an acoustic modelling study for MODU DP activities is planned. Noise Modelling was conducted to support the FLNG EIS/ERD (Duncan 2014) where the acoustic source spectra for the FLNG facility during normal operations were based on a generic FPSO facility. It is considered that the noise assumed to be produced by the FLNG facility in the Duncan (2014) study is sufficiently representative of the Torosa FPSO facility which represents the worst-case scenario with respect to FPSO noise generation for the Proposed Action. As such, it is considered that the Duncan (2014) study is appropriate to describe the impact of noise on sensitive receptors originating on the Torosa FPSO and no further modelling of FPSO generated noise is required. Woodside modelled underwater noise generated by subsea choke valves (Duncan, 2010) within wellheads to support the FLNG EIS/ERD. This modelling was undertaken for the Torosa D (TRD) and Torosa E (TRE) subsea manifolds (i.e. located in channel between North and South Scott Reef) which is considered worst case with respect to underwater noise impacts It is considered that this modelling is representative for the proposed Browse to NWS Project and no further modelling is considered required. It is also noted that relative to the FLNG EPBC approval (2013/7079), in addition to TRE, the TRD drill centre is now planned to be installed post Ready for Start Up (RFSU). This will allow Woodside to monitor both choke noise emissions from wells outside the channel, plus pygmy blue whale presence/absence in the area prior to the installation of wells at TRD and TRE. As outlined during assessment of 2013/7079 there is potential to further mitigate choke noise for post RFSU wells if warranted. While considered unlikely to be required, driving piling is considered a planned contingent activity that will be used in the event suction piling is not feasible in any area due to geotechnical conditions. Available noise modelling of pile driving activities is not considered sufficient to support the environmental impact assessment of this activity in the EIS/ERD, and as such Browse to NWS Project specific modelling is required.	Literature review of Woodside owned and publicly available information including a review of applicable State and Commonwealth guidance and conservation plans. Implementation of a subsea piling acoustic modelling study to generate predictions of the ensonified area and ranges to acoustic thresholds and estimate acoustic exposure to pygmy blue whales and green turtles. Implementation of acoustic modelling study for MODU DP activities to generate predictions of the ensonified area and ranges to acoustic thresholds and estimate acoustic exposure to pygmy blue whales and green turtles.
IMP-2	Light emissions – MODU and FPSO including flaring	Understand and assess potential impacts to sensitive receptors (marine fauna) resulting from the generation of light emissions.	Woodside has a good understanding with respect to the light emissions generated from the proposed activities via studies undertaken for the previous Browse Development concepts. Light emissions from construction and operation activities were modelled (ERM 2010 and Jacobs 2014) as part of the two previous Browse Development concepts (JPP and FLNG). It is considered that the source light levels for the proposed FPSO facilities are similar to those previously modelled as part of the previous studies, with the overall artificial light footprint likely to be smaller due to the significantly reduced size of the facilities. Given the similarities between the previous concepts and the proposed Browse to NWS Project (with potential reduction in light emissions) it is considered that these studies adequately define the potential impacts from artificial light emissions associated with the development.	Literature review of Woodside owned and publicly available information including a review of applicable State and Commonwealth guidance and conservation plans. Use of previous modelling to inform impact assessment.
IMP-2b	Light emissions – vessels			
IMP-3a, Risk 10	Physical presence of infrastructure during construction	Understand and assess potential impacts to sensitive receptors (marine fauna, benthic habitat) resulting from the physical presence of infrastructure during construction and operations.	Woodside has a detailed understanding of the extent of temporary and permanent seabed disturbance as well as the number, frequency and location of surface facilities and support vessels. As detailed in **Table 6** Woodside has a good understanding of the seabed that is expected to be disturbed and is undertaking an environmental survey, including benthic habitat study of the BTL corridor (refer to Section 3.7.6). This information is considered sufficient to define the impacts associated with the physical presence of the infrastructure.	Literature review of Woodside owned and publicly available information to inform impact assessment including the calculation of predicted seabed disturbance.
IMP-3b, Risk 10	Physical presence of infrastructure during operations			

ID	Aspect	Key Aim	Assessment of Current Level of Understanding	Workplan
IMP-4a	Gaseous emissions - air emissions	Predict impact to local air quality as a result of gaseous emissions	Woodside has sufficient understanding of the characteristic of the Browse resource and the combustion requirements to extract, process and export the gas to accurately quantify gaseous emissions. As such no further studies are considered required. In relation to GHG assessment refer to Section 3.9. Woodside will point to and provide context for the assessment of the potential impacts of the North West Shelf Project Extension Proposal (EPBC 2018/8335) on values specifically related to the National Heritage listing on the Burrup Peninsula.	Literature review of Woodside owned and publicly available information to inform impact assessment In relation to GHG assessment refer to Section 3.9. The assessment documentation must provide details of any potential indirect impacts of the proposed action on the (Indigenous rock art) values of the Dampier Archipelago (including the Burrup Peninsula) National Heritage Place, and the extent to which these values may be impacted by the proposed action following any planned mitigations. .
IMP-4b	Gaseous emissions - GHG	In relation to GHG assessment refer to Section 3.9.		
IMP-5	Treated sewage	Understand and assess impact of the discharged of treated sewage.	Sewage generated during the Proposed Action will be treated and disposed of in accordance with MARPOL 73/78Annex IV: Sewage – (as applied in Australia under Commonwealth *Protection of the Sea (Prevention of Pollution from Ships) Act* 1983); AMSA Marine Orders - Part 96: Marine Pollution Prevention – Sewage. as applicable to vessel class. As such, no further studies are considered to be required.	Literature review of Woodside owned and publicly available information to inform impact assessment.
IMP-6, Risk 2	Treated PW and NORMs.	Understand and assess potential impacts resulting from the discharge of PW and NORMS from the FPSO, including the extent of impact based on the determination of Predicted No Effect Concentrations (PNEC) and the mixing zone.	Woodside has a good understanding of the predicted PW discharge rates and composition. However, confirmation of the dilution rate that will be achieved from the FPSO facilities and the extent of the mixing zone is required. PW discharges were modelled during the assessment of the previous Browse development concepts (DHI 2011, DHI 2014). The modelling undertaken for the FLNG EIS (DHI 2014) predicted that the PW plume would disperse to below toxicity threshold concentrations within less than 3 km from the facility. PW emissions from the FPSO facilities are expected to be broadly similar (other than MEG concentrations are likely to be pulsed at high concentrations as opposed to continuous trace concentrations). There is potential for PW volumes and discharge rates to increase during later field life to levels above predicted in the Browse FLNG EIS. Due to the increase in PW volume and discharge rates late in field life, the existing modelling can only inform the scope of the new modelling and cannot be used to inform the impact assessment. Ecotoxicology studies to determine the safe concentration of Browse PW for 99% of species protection have previously been undertaken and will be used to inform the interpretation of the PW modelling study.	Literature review of Woodside owned and publicly available information to inform impact assessment. Implementation of a PW Dispersion Modelling study to predict the fate and transport of PW discharges from the FPSO in order to determine the number of dilutions achieved from the FPSO facilities, which is required to determine an appropriate mixing zone, outside which no impacts to the receiving environment are predicted. The PW Dispersion Modelling will also be used to inform predictions of the extent, severity and persistence of environmental impacts within the defined mixing zones.
IMP-7a, Risk 3	Treated utility water – drain discharges	Understand and assess impact of the discharge of treated utility water.	Drain discharges generated during the Proposed Action will be treated and disposed of in accordance with MARPOL 73/78 Annex I, as applied in Australia under the Commonwealth *Protection of the Sea (Prevention of Pollution from Ships)* Act 1983 (Part II Prevention of pollution from oil); Marine Orders 91 (Marine pollution prevention – Oil) 2006 as applicable to vessel class; and the *Pollution of Waters by Oil and Noxious Substances Act* 1987 (WA).	Literature review of Woodside owned and publicly available information to inform impact assessment.
IMP-7b	Treated utility water – desalination brine	Understand and assess impact of the discharge of treated desalination brine.	Woodside has a good understanding of the expected desalination brine discharge rates and composition. Given the low likelihood of significant impacts occurring, no further studies are considered required.	Literature review of Woodside owned and publicly available information to inform impact assessment.
IMP-8, Risk-4	Cooling water	Understand and assess potential impacts resulting from the discharge of cooling water from the FPSO including the determination of the mixing zone.	Woodside has a good understanding of the predicted cooling water discharge rates and composition. However, confirmation of the extent of the mixing zone is required. Cooling water discharges were modelled during the assessment of the previous Browse Development concepts (DHI 2011a, DHI 2014). The modelling undertaken for the FLNG EIS (DHI, 2014) predicted that temperatures would return to with 3 degrees of ambient temperature within 190 m of the discharge point in winter and 110 m or less in summer. The modelling also predicted that residual chlorine concentrations in cooling water (0.2ppm) will reduce down-current of the discharge point to threshold concentration (0.002ppm) within 1.4 km or less in winter and within shorter distances in the transitional and summer seasons (1.3 km or less and 1.1 km or less respectively) for 95% of the time. Cooling water emissions from each of the FPSO facilities are expected to be significantly reduced compared to those assessed for Browse FLNG EIS and as such the existing modelling can only inform the scope of the new modelling and cannot be used to inform the impact assessment.	Literature review of Woodside owned and publicly available information to inform impact assessment. Implementation of a Cooling Water Dispersion Modelling study to predict the fate and transport of cooling water discharges from the FPSO in order to determine the mixing zone, outside which no impacts to the receiving environment are predicted. The Cooling Water Dispersion Modelling will also be used to inform predictions of the extent, severity and persistence of environmental impacts within the defined mixing zones
IMP-9	Putrescible organic waste	Understand and assess impact of the discharge of putrescible organic waste and the risks associated with the accidental discharge of hazardous and non-hazardous inorganic	Woodside has a good understanding of the expected organic and non-organic wastes expected to be generated during the proposed Browse to NWS Project. These wastes will be managed in accordance with legislative requirements. No further studies are	Literature review of Woodside owned and publicly available information to inform impact assessment.
IMP-10, Risk-5	Inorganic non-hazardous waste			

ID	Aspect	Key Aim	Assessment of Current Level of Understanding	Workplan
IMP-10, Risk-6	Hazardous waste - chemicals, radioactive and medical	waste.	considered required.	
IMP-12, Risk-7	Drilling cuttings and fluids	Understand and assess impact of the discharge of drill cuttings on sensitive receptors.	Woodside has a good understanding of the quantity and nature of the drill cuttings that are predicted to be generated and the drill fluids to be used. There is also a good understanding on the predicted fate of the discharges via drilling cuttings discharge modelling undertaken as part of the previous Browse Development concepts (DHI 2011b). This modelling indicated predicted that the seabed discharge of drill cuttings from top hole sections of the wells results in no sedimentation on Scott Reef coral habitats. This modelling was based on drill centres in the channel between North and South Scott reef and is considered to be representative of the worst case scenario. Drilling and completion activities required for the proposed Browse to NWS Project area expected to be broadly similar to that of the previous development concepts. As such the previous modelling is considered representative and sufficient for assessing the potential impacts.	Literature review of Woodside owned and publicly available information to inform impact assessment. Use of previous modelling to inform impact assessment.
IMP-13	Subsea control fluid	Understand and assess impact of the discharge of subsea control fluid.	Woodside has a good understanding of the quantity and nature of the subsea control fluid to be discharged. These discharges are minor, similar to that predicted for previous Browse development concepts and with a negligible impact predicted. As such further studies are not considered necessary.	Literature review of Woodside owned and publicly available information to inform impact assessment.
IMP-14	Hydrotest fluid	Understand and assess potential impacts resulting from the discharge of hydrotest fluid including the determination of the mixing zone.	Hydrotest fluid discharge modelling was not undertaken as part of the previous Browse development concepts due to the relatively small amount of hydrotest fluid that was planned to be released. Significantly larger quantities may be discharged as part of the proposed Browse to NWS Project however, due to the potential requirement to hydrotest the BTL. As such, modelling is considered required to predict the fate and transport of hydrotest discharges to inform the impact assessment.	Literature review of Woodside owned and publicly available information to inform impact assessment. Implementation of a Hydrotest Dispersion Modelling Study to predict the fate and transport of hydrotest discharges from the BTL in order to determine the number of dilutions achieved, which is required to determine an appropriate mixing zone, outside which no impacts to the receiving environment are predicted. The Hydrotest Dispersion Modelling will also be used to inform predictions of the extent, severity and persistence of environmental impacts within the defined mixing zones.
IMP-15	Atmospheric Noise	Understand and assess potential impacts resulting from Atmospheric Noise Emissions resulting from helicopter movements	Woodside has a good understanding of the noise emissions from helicopter movements and no further studies are considered necessary.	Literature review of Woodside owned and publicly available information to inform impact assessment.
Risk-1	IMS	Understand and assess the potential risks associated with the introduction of IMS.	The risk of the introduction of IMS as a result of the project will be managed in accordance with legislative requirements. No further studies are considered necessary.	Literature review of Woodside owned and publicly available information to inform impact assessment.
Risk-8	Seabed subsidence	Understand and assess the potential risks associated with seabed subsidence as a result of the extract of the Browse resource.	Woodside has modelled the magnitude of subsidence and associated horizontal movements for the Browse reservoirs as part of the previous Browse Development concepts. This analysis has been peer reviewed by Baker Hughes GMI Geomechanics Services (Baker Hughes 2012) who concluded that the method and supplied data was appropriate. The DoEE sought further independent review by CO2 Geological Storage Solutions Pty Ltd (CGSS) (CGSS 2012) who found that the report conclusions were reasonable. As such Woodside has sufficient understanding of the risks associated with seabed subsidence and no further studies are considered necessary.	Literature review of Woodside owned and publicly available information to inform impact assessment.
Risk-9	Hydrocarbon spill	Understand and assess the potential risks associated with a hydrocarbon spill.	Woodside has modelled multiple hydrocarbon spill scenario as part of the previous Browse development concepts. However, given ongoing improvements in modelling and understanding of conditions, and the addition of the BTL, a Hydrocarbon Spill Modelling study will be undertaken.	Literature review of Woodside owned and publicly available information to inform impact assessment. Implementation of a Hydrocarbon Spill Modelling study to describe the dispersion and degradation characteristics of a range of hydrocarbon spill scenarios.

3.8.8 Scope of Technical Studies informing Impact and Risk Assessment

The following technical studies will be undertaken to inform the impact and risk assessment. Where applicable the assessment will be done in consideration of the Revised Australian and New Zealand Guidelines for Fresh and Marine Water Quality 2018 (ANZG (2018)) which provide the recommended limits to acceptable change in water quality that will continue to protect the associated environmental values.

Subsea Piling and MODU DP Acoustic Modelling

Acoustic modelling of the subsea impact pile driving operations for the mooring of the Torosa FPSO facility and of the MODU DP will be undertaken. The objective of this study is two-fold:

- to generate predictions of the ensonified area and ranges to acoustic thresholds that may result in injury to or behavioural disruption of cetaceans, turtles and fish near the construction area; and
- estimate acoustic exposure to pygmy blue whales and green turtles.

For the subsea impact pile driving operations, modelling will be undertaken for the following scenarios for a single pile type:

1. One ‘light’ subsea hammer
2. One ‘high energy’ subsea hammer

Both scenarios will be modelled at the same location using conservative assumptions from the provided information. Footprints for impact pile driving will be computed at three penetrations, and a combined footprint for the entire driving of a single pile will be computed. The modelling will assume a single pile will be driven per day.

Exposures for pygmy blue whales and inter-nesting green turtles will be assessed using a simulated animal (animat) approach. This approach will use acoustic modelling to compute three-dimensional (3-D) sound fields that vary with time, and simulated realistic movements of animats within these fields to sample the sound levels in a manner representing how real animals would experience this sound. Using the time history of the received sound levels, the number of animats exposed to levels exceeding threshold criteria will be determined and then adjusted by the number of animals in the area to estimate the potential number of animals impacted.

Produced Water Dispersion Modelling

PW dispersion modelling will be undertaken to predict the fate and transport of PW discharges from the FPSO in order to determine the number of dilutions achieved from the Browse FPSO facilities, which is required to determine an appropriate mixing zone, outside which no impacts to the receiving environment are predicted. It will also be used to inform predictions of the extent, severity and persistence of environmental impacts within the defined mixing zones.

The proposed modelling will describe the dispersion geometry (i.e. width and thickness with distance) and dilution characteristics of the discharge plume, it has been determined that hydrocarbons are the most toxic constituent of the PW discharge, with other potential contaminants such as metals present in less toxic concentrations. In addition additional production chemicals will not be continuously injected. Hence, the toxicity values used to characterise impacts to marine organisms has been derived from ecotoxicological studies conducted on Torosa condensate samples.

The modelling will take into consideration all relevant metocean parameters of the receiving environment including seasonal fluctuations as well as parameters from possible discharge scenarios (e.g. discharge location, water depth, discharge pipe diameter and orientation, and discharge volume, density, temperature and salinity). In addition, validation of the hydrodynamic model against measured data will be undertaken.

This information will be used as part of the environmental impact and risk assessment process of the EIS/ERD to determine the impacts (if any) to the receiving environment from the PW discharge and to determine the extent of the mixing zone around the Torosa FPSO discharge location (as the worst-case scenario due to the location in proximity to Scott Reef). The modelling will then also be applied to the Brecknock/Calliance FPSO facility to enable assessment of impacts from both facilities.

Cooling water dispersion modelling

Cooling water dispersion modelling will be undertaken to predict the fate and transport of cooling water discharges from the FPSO in order to determine the number of dilutions achieved from the Browse FPSO facilities, which is required to determine an appropriate mixing zone, outside which no impacts to the receiving environment are predicted. It will also be used to inform predictions of the extent, severity and persistence of environmental impacts within the defined mixing zones.

The proposed modelling will describe the dispersion geometry (i.e. width and thickness with distance) and dilution characteristics of discharge plume. This information will be used as part of the environmental risk assessment process of the EIS/ERD to determine the impacts (if any) to the receiving environment from the cooling water discharge and to determine the extent of the mixing zone around the Torosa FPSO discharge location outside which no detectable change from natural variation is predicted. The modelling will then also be applied to the Brecknock/Calliance FPSO facility to enable assessment of impacts from both facilities.

Modelling will take into consideration all relevant metocean parameters of the receiving environment including seasonal fluctuations as well as parameters from possible discharge scenarios (e.g. discharge location, water depth, discharge pipe diameter and orientation, and discharge volume, density, temperature and salinity).

Hydrotest Dispersion Modelling (BTL and Inter Field Spur Line)

Hydrotest modelling will be undertaken to predict the fate and transport of hydrotest discharges, in order to determine the number of dilutions achieved within the receiving environment. Modelling will be undertaken at all potential locations for planned discharge of hydrotest fluid from the BTL and Inter-Field Spur Line. Discharge of the hydrotest fluid from the flowlines will be discharged at the similar locations as the Inter-Field Spur line and will invoice discharge of volumes many orders of magnitude less than the spur line. As such, the potential impacts associated with the flowline hydrotest have been adequately assessed within the larger hydrotest volume.

For the purpose of modelling the BTL and Inter-Field Spur Line and the associated risk assessment, it has been assumed that the hydrotest fluid will consist of a combination of filtered inhibited seawater and biocide. The 99% species protection for biocide chemical (nominally product name Hydrosure) will be used as the threshold.

The proposed modelling will describe the dispersion geometry (i.e. width and thickness with distance) and dilution characteristics of discharge plume. This information will be used as part of the environmental risk assessment process of the EIS/ERD to determine the impacts (if any) to the receiving environment from the hydrotest discharges based on the known toxicities of the chemical additives within the hydrotest waters.

Hydrocarbon Spill Modelling

Hydrocarbon spill modelling will be undertaken to describe the dispersion and degradation characteristics of a range of hydrocarbon spill scenarios. This information will be used as part of the environmental risk assessment process of the EIS/ERD to determine the impacts (if any) to the receiving environment from hydrocarbon spills.

The credible hydrocarbon spill scenarios to be modelled are as follows:

- Hydrocarbon release caused by loss of well containment

- Hydrocarbon release due to cargo tank or condensate tanker loss of containment
- Hydrocarbon release during offtake operations
- Hydrocarbon release from fuel tanker in proximity to Rowley Shoals.

It is not proposed to model the release of dry gas from the BTL as the high temperature and low-pressure conditions would result in the released dry gas combining with water to form hydrates which would rise to the surface, decompose into methane and water. Dissolved methane would biodegrade whereas the gaseous methane will continue to rise to the sea surface and be transported away by surface winds. Water produced by the dissociation of hydrates would disperse within the water column. Due to this, the release of liquid hydrocarbons (as per the above four scenarios to be modelled) are considered the worst case credible scenarios. A detailed technical explanation and appropriately-supported evaluation of the fate and effect(s) on the environment of a release of dry gas will be included in the EIS/ERD.

It is also not proposed to model heavy fuel oil (HFO) and Marine Diesel Oil (MDO) spills from vessels. Based on the International Maritime Organisation's decision to implement a 0.50% sulphur cap on marine fuel from 2020, the assumption is being made that there will be no HFO, which have sulphur levels much higher than this cap, in use or stored onboard any of the project vessels. While MDO may be considered worse from a contaminant perspective than condensate, due to the significantly higher volumes of condensate involved in a condensate tanker loss of containment at a nearby location, this scenario is considered to be a worse case credible scenario in the vicinity of Scott Reef.

Modelling will take into consideration all relevant metocean parameters of the receiving environment including seasonal fluctuations as well as parameters from possible discharge scenarios (e.g. discharge location, water depth, discharge pipe diameter and orientation, and discharge volume, density, temperature and salinity).

Modelling will be undertaken with regard to NOPSEMA's Guidance Note on Oil pollution risk management (Rev 2, Feb 2018).

3.9 Greenhouse Gases

As requested by the Commonwealth DoEE, this chapter will summarise:

1. receptors in the environment in the Australian jurisdiction that are sensitive to an increase in greenhouse gas (GHG) content in the atmosphere - the focus should be on the most sensitive receptors, and receptors that may be sensitive to elevated GHG levels in the local airshed
2. trends in the condition of the receptors identified at point 1
3. the (direct and indirect, or Scope I–III) GHG emissions from the Proposed Action (sources and volumes, see also point 1 in Appendix A)
4. how the (total of direct plus indirect) GHG emissions from the Proposed Action could impact the receptors identified at point 1
5. mitigation and any offset measures proposed to reduce: GHG emissions from the Proposed Action; and their impacts (see also point 2 in Appendix A) - this section will include a discussion of the steps taken at the: company, Burrup Hub vision and this individual project level, to reduce GHG emissions
6. how the Scope I GHG emissions from the Proposed Action will be estimated (see point 3 in Appendix A)
7. how the Scope II and III GHG emissions from the Proposed Action will be estimated
8. the extent to which the direct and indirect GHG emissions from the Proposed Action will affect the trends in the condition of the receptors identified at point 1

9. relevant Australian and international legislation and policy in relation to the management of climate change.

Note: Without limiting what is required, the EIS/ERD must (a) identify those components of the environment in the Australian jurisdiction that are most likely to be impacted by climate change/most vulnerable to the impacts of climate and assess in detail the likely flow-on consequences of such an increase in atmospheric, air and water temperatures to those components of the environment; and (b) for all other components of the environment in the Australian jurisdiction, assess the likely impacts of climate change at a higher level (for instance, a more general discussion and/or impacts on types of ecosystems, heritage places, terrestrial habitat, marine habitat, migratory species).

3.10 Environmental Mitigation, Management and Monitoring

3.10.1 Environmental Management Framework

An environmental management framework will be described within the EIS/ERD. This will include:

- Overview of Woodside's HSE Management System Standard
- Health, Safety, Environment and Quality (HSEQ) Policy
- Standards
- Environmental Objective
- Processes for implementing, checking and acting on relevant environmental management measures as the Project is developed.

3.10.2 Management and Mitigation

As part of the EIS/ERD process, management and mitigation measures will be identified to reduce the level of impact and risk to an acceptable level in consideration of the EPBC Act, EP Act and other relevant policy instruments. This includes any practices that will reduce the impacts and risks in order to meet the identified performance criteria, any relevant legal requirements (related specifically to the impact/risk), internal company requirements, and any requirements that are identified through the stakeholder consultation process. It should be noted that further review and potential adoption of additional controls will be undertaken in subsequent phases of the project, such as during the preparation of Environment Plans (EPs) for activities under the scope of the EIS/ERD. While the overarching environmental objectives will be carried through to the EPs, controls and corresponding performance criteria will be implemented to reduce risks to as low as reasonably practicable (ALARP).

In accordance with Woodside's risk management standards and for the purpose of the draft EIS/ERD, where a risk is assessed to be low, this risk will be deemed acceptable, and no further management is required. Where the risk level is higher than low, additional management and mitigation measures are required to be considered and implemented, if the cost is not grossly disproportionate to the environmental benefit gained, to prevent or mitigate the risk to an acceptable level.

The following framework tools will be applied, as appropriate, to assist with identifying appropriate management and mitigation measures:

- Good Industry Practice – identifies further engineering control standards and guidelines which may be applied by Woodside in addition to those required to meet the legislation, codes and standards.
- Professional Judgement – uses relevant personnel with the knowledge and experience to identify alternative controls.

Using these tools, the following adaptive management framework will be used to identify appropriate management and mitigation measures for the proposed Browse to NWS Project:

- Eliminate the risk by removing the hazard.
- Substitute a hazard with a lesser one.
- Prevent a credible impact from occurring through the implementation of additional engineering control measures.
- Reduce the magnitude of a credible impact through the implementation of additional engineering control measures (e.g. solids control equipment onboard drilling rig to manage cuttings discharge).
- Mitigate the credible impact on the environment through the reduction in extent, scale, duration of impact (e.g. bunding, oil spill booms, relief well).
- Emergency response and contingency planning to facilitate recovery from the credible impact of an event.

Environmental objectives, proposed mitigation and management measures and performance criteria will be presented in the EIS/ERD.

3.10.3 Environmental Monitoring

Woodside will continue a long-term environmental monitoring program at Scott Reef, including water quality and coral health monitoring, that will be implemented prior to development at Torosa; with the results of this program used to demonstrate no long-term negative effects to Scott Reef resulting from the proposed Browse to NWS Project. The EIS/ERD will describe the objectives and scope of this long-term monitoring.

Where identified as required, additional planned monitoring will be described including the objective and scope of specific monitoring plans. These plans would subsequently be developed prior the commencement of the relevant activity and would take into consideration relevant guidance such as the Revised Australian and New Zealand Guidelines for Fresh and Marine Water Quality 2018 (ANZG(2018)).

3.10.4 Environmental Offsets

In the event that impacts cannot be avoided or mitigated, the EIS/ERD will provide detail of the approach to be applied to offsetting impacts. It should be noted that offsets for GHG emissions are addressed separately in Section 3.9. This approach will include a commitment to develop an offsets plan that would provide details of offsets proposed to compensate for residual impacts on EPBC listed species, including the following:

- The type of offsets proposed
- The extent to which the proposed offset actions correlate to, and adequately compensate for, the impacts to EPBC listed species
- For proposed land-based offsets, the suitability of the location of proposed offset sites, including the current land tenure and method of securing and managing the offset for the life of the impact
- For non-land-based offsets, details of the proposed offset and how it will compensate for the proposal’s residual significant impacts
- The conservation gains to be achieved by the offset (for example, positive management strategies that improve the site, or how the future loss, degradation or damage of the protected matter will be averted or mitigated)

- The time it will take to achieve the proposed conservation gains
- The level of certainty that the proposed offset will be successful.

The EIS/ERD will explain how the proposed approach to applying offsets (if any) meet the principles of the Environment Protection and Biodiversity Conservation Act 1999 Environmental Offsets Policy (2012).

3.11 Overall Conclusion

An overall conclusion as to the environmental acceptability of the Proposed Action and State waters proposal will be provided, including discussion on compliance with the principles of Ecological Sustainable Development and the objects and requirements of the EPBC Act and EP Act. This will include a qualitative assessment of the cumulative impacts on each key receptor and assess impacts on a more holistic, whole-ecosystem level, considering the potential cumulative impacts of the proposed project, and any existing and future concurrent activities, on the existing environment.

Reasons justifying undertaking the Proposed Action and State waters proposal in a manner proposed will be outlined.

The conclusion will highlight measures proposed or required by way of mitigating or managing any unavoidable impacts on the environment.

Measures proposed by way of offset and the change in residual impacts following the offset will be restated here.

3.12 Other Chapters

3.12.1 Environmental record of person(s) undertaking the Proposed Action

This chapter will outline the environmental record of the proponent including:

- details of any proceedings under Commonwealth, State or Territory law for the protection of the environment or the conservation and sustainable use of natural resources against:
    - the person proposing to take the action; and
    - for an action for which a person has applied for a permit, the person making the application.
- details of the Woodside's HSEQ policy and planning framework.

3.12.2 Information Sources

For information given in a draft EIS/ERD, the draft must state:

- the source of the information
- how recent the information is
- how the reliability of the information was tested
- what uncertainties (if any) are in the information.

3.12.3 References

All reference cited within the draft EIS/ERD will be listed. This will be accurate and concise and include the addresses of an internet pages used as source data.

4. PART C: STATE ESD

Proposal Name:	Proposed Browse to NWS Project
Proponent:	Woodside Energy Ltd., as Operator for and on behalf of the BJV
Assessment Number:	2191
Location:	• Approximately 425 km north of Broome, WA. • The Browse Joint Venture (BJV) holds seven petroleum retention leases. Five of the leases (WA-28-R, WA-29-R, WA-30-R, WA-31- R and WA-32-R) are located in Commonwealth waters and are governed under the Offshore Petroleum and Greenhouse Gas Storage Act 2006 (Cth) (OPGGSA). The remaining two leases (TR/5 and R2) are governed under State legislation Petroleum (Submerged Lands) Act 1982 (WA) (PSLA) and the Petroleum and Geothermal Energy Resources Act 1967 (WA) (PGERA).
Local Government Area:	Lease R2 is linked to the Shire of Broome via the Local Govt Act 1995 (WA)
Public Review Period:	Environmental Review Document – 6 weeks
EPBC Reference Number:	2018/8319

4.1 Introduction

The Environmental Protection Authority (EPA) has determined that the Browse to NWS proposal is to be assessed under Part IV of the Western Australian (WA) Environmental Protection Act 1986 (EP Act). This EISG/ESD defines the form, content, timing, and procedure of the environmental review, as required by Section 40(3) of the EP Act. Woodside Energy Ltd. (Woodside) has prepared this EISG/ESD according to the EPA’s Environmental Impact Assessment (Part IV Division 1 and 2) Procedures Manual (EPA 2018a).

4.1.1 Form

The EPA requires that the Environmental Review Document (ERD) required under Section 40 conforms with the EPA instructions on how to prepare an ERD (EPA 2018).

4.1.2 Content

The EPA requires that the ERD includes the content outlined in Sections 4.1 to 4.6 of this EISG/ESD.

4.1.3 Timing

Section 1.1.3.2 sets out the timeline for assessing the Browse to NWS proposal, as agreed between DoEE, EPA and Woodside which will be documented in a DoEE issued Client Service Charter.

4.1.4 Procedure

The EPA requires Woodside to undertake the environmental review according to the procedures in the Environmental Impact Assessment (Part IV Divisions 1 and 2) Administrative Procedures (EPA 2016a) and the Environmental Impact Assessment (Part IV Divisions 1 and 2) Procedures Manual (EPA 2018a).

4.1.5 Assessment

As described in Section 1.1.3.2, the assessment of the Proposed Action under the EPBC Act and State waters proposal under the EP Act is planned to be undertaken as a coordinated assessment between the DoEE and WA EPA. The National Offshore Petroleum Safety and Environmental Management Authority (NOPSEMA) will be engaged to provide technical advice to the DoEE in relation to the assessment.

This approach includes the following:

- Simultaneous referrals under the EPBC Act and EP Act, which was completed in October 2018.
- The development of a single EISG/ESD (this document), which describes the proposed content of an Environment Impact Statement/Environmental Review Document (EIS/ERD). This ESD will be issued to DoEE and EPA for review and endorsement.
- The development of a single draft EIS/ERD document that is issued to DoEE and EPA for comment on adequacy and approval, prior to release for public comment.
- The preparation of a single final EIS/ERD document. The final EIS/ERD will be submitted to the DoEE and WA EPA for assessment and to be published.
- Decision on the acceptability of the Proposed Action and the State waters proposal.

Subsequent to a favourable decision on the acceptability of the proposed Browse to NWS Project, and prior to any development activity occurring in State waters, Environment Plans (EPs) including Oil Spill Contingency Plans (OSCP) will be developed for approval by the Department of Mines, Industry Regulation and Safety (DMIRS) in accordance with the Petroleum (Submerged Lands) (Environment) Regulations 2012.

4.2 The proposal

Refer to Section 2.2 for a description of the Proposed Action, while for the proposal relevant to State waters see Section 4.2.1.

4.2.1 Development in Western Australian State waters

The key characteristics of the proposal within State waters are described in **Table 13** and **Table 14** and shown in **Figure 1**.

Activities in State waters comprise a limited set of infrastructure and activities (**Table 13** and **Table 14**). The highest intensity of activities will likely occur during the drilling and completion activities, installation activities and future decommissioning phases; during which time, a MODU and vessel numbers of approximately ten or less may be present in the State waters. All the proposed infrastructure within State waters is subsea, with the operation of the wells to be controlled remotely from the FPSO facilities in Commonwealth waters. Outside of drilling, completion and installation periods, surface activities in State waters will comprise inspection, maintenance and repair (IMR) activities involving one or two vessels, later phase drilling and decommissioning (including well plugging and abandonment).

Proposal characteristics may change as a result of the findings of studies and investigations conducted and the application of the mitigation hierarchy by Woodside.

Table 13 Summary of the Proposal

Proposal Summary	
Proposal Title	Proposed Browse to NWS Project (State waters components)
Proponent Name	Woodside Energy Ltd, on behalf of the BJV participants
Short Description	Drilling and completion, installation, commissioning, operation, well repair and workover and decommissioning of subsea wells and associated subsea infrastructure located in Western Australian State waters, to extract hydrocarbons from the Torosa reservoir, located approximately 425 km north of Broome and approximately 290 km off the Kimberley coast.

Table 14 Location and proposed extent of physical and operational elements

Element	Description	Proposed Authorised Extent
Physical Elements		
Drilling and completion activities of up to approximately 21 wells.	Installation and physical presence of infrastructure within indicative field layout as per **Figure 1**	Approximately 20 ha of seabed.
Associated subsea infrastructure (wellheads, manifolds, flowlines, and umbilicals).		
Mooring of vessels and MODU.		
Seabed preparation and flowline stabilisation.		
Operational Elements		
Water supply (installation vessels, MODU, support vessels and supply vessels).	Water requirements sourced either from seawater (reverse osmosis plant) or loaded at port.	Limited water requirements to support drilling and completion activities, vessel and MODU water needs and potentially also for hydrotesting and decommissioning activities.
Power supply (installation vessels, MODU, support vessels and supply vessels).	Power generated on board vessels and MODU.	As required for operations and safety.
Vessel discharges (installation vessels, MODU, support vessels and supply vessels).	Discharges from vessels and MODU include treated sewage, drain waters, cooling water, sullage, putrescible organic waste and desalination brine.	Limited volumes discharged in accordance with International Convention for the Prevention of Pollution from Ships MARPOL 73/78 Annex I, as applied in Australia under the Commonwealth *Protection of the Sea (Prevention of Pollution from Ships) Act 1983* (Part II Prevention of pollution from oil); Marine Orders 91 (Marine pollution prevention – Oil) 2006 as applicable to vessel class; *Pollution of Waters by Oil and Noxious Substance Act 1986.*
Drill cuttings and fluid discharges.	Disposal of drill cuttings and drilling fluids.	Approximately 800 - 900m^3 of cuttings are anticipated to be

Element	Description	Proposed Authorised Extent
		generated per well.
Produced water.	Small volumes of formation water may result during well clean-up activities by the MODU. These will be discharged directly from the MODU.	Low volumes of water that occurs naturally within the hydrocarbon-bearing geological formations.
Subsea control fluid discharge.	Discharge of control fluid at the wellheads to maintain valve functionality.	Intermittent discharge of hydraulic fluid based control fluids when valves actuated (~0.1 L).
Underwater noise emissions.	Underwater noise generated during drilling, completion and installation activities (including vessel movements on DP and vertical seismic profiling). Underwater noise generated from subsea infrastructure during operations. Underwater noise from piling activities for mooring installation for the MODU (note that this is unlikely to be required). Underwater noise from support vessel and supply vessel operations.	Noise frequencies associated with these activities are described in the Proposed Browse to NWS Development, *Environment Protection and Biodiversity Conservation Act 1999* (Cwlth) (EPBC Act) and EP Act Environmental Referrals Supporting Document (Woodside, 2018).
Light emissions – operational lighting	Artificial light emitted by MODUs, installation vessels, and support vessels and supply vessels.	Limited to functional lighting at levels that provide a safe working environment for personnel.
Light emissions – flaring	Intermittent flaring from the FPSO facilities (located in Commonwealth waters) and MODU.	As required for operations and safety.

4.3 Preliminary key environmental factors and required work

The preliminary key environmental factors for the environmental review are:

- Benthic Communities and Habitat
- Marine Environmental Quality
- Marine Fauna
- Air Quality.

Table 15 to **Table 18** outline the objective, activities, potential impacts and risk and work required for each preliminary key environmental factor identified.

Table 15: Preliminary Key Environmental Factor and Required Work – Benthic Communities and Habitats

Benthic Habitats and Communities	
EPA Objective	To protect benthic communities and habitats so that biological diversity and ecological integrity are maintained (EPA 2016c).
Relevant Activities	• Development drilling and completions • Installation of subsea umbilicals, risers and flowlines • Operation of wells and subsea infrastructure • Decommissioning.
Potential Impacts and Risks	Refer to **Table 7** and **Table 8** for the preliminary impact and risk assessments for the proposed Browse to NWS Project. In relation to the proposal within State waters, the following impacts and potential risks are considered relevant to the Environmental Factor - Benthic Habitats and Communities: • IMP-3a Physical presence of infrastructure during construction: Seabed disturbance from seabed preparation and MODU anchors. No impact to Scott Reef is expected. • IMP-3b Physical presence of infrastructure during operations: Permanent seabed disturbance from subsea infrastructure • IMP-12 Drilling cuttings and fluids: Localised impact to deep water benthic habitats as a result of the discharge of drill cuttings. • Risk-9 Hydrocarbon spill: Long term contamination to multiple high value benthic habitats at levels above standards and on a regional scale. Considered highly unlikely to occur.
Required Work	Refer to **Table 12** for the full impact and risk assessment workplan. Refer to Section 3.8.8 for the scope of the proposed technical studies. In reference to the Environmental Factor – Benthic Habitats and Communities: • Determination of predicted temporary and permanent seabed disturbance within State waters. • Characterise the benthic habitats in the area potentially impacted using existing survey data and literature, including the preparation of habitat maps with demonstrated ground truthing for areas where proposed infrastructure will be installed on the seabed within State waters. Woodside has a good understanding of the benthic habitats expected to be disturbed within State waters and as such no further studies to characterise these benthic habitats is considered required. • Where significant benthic communities are identified in areas where infrastructure will be installed on the seabed, identify an appropriate Local Assessment Unit and assess cumulative loss of benthic communities and habitats in accordance with EPA's technical guidance (EPA 2016). • Predict the likely fate of discharged drill cuttings using existing data and modelling and assess impact on benthic habitats. Woodside has a good

Benthic Habitats and Communities	
	understanding of the quantity and nature of the drill cuttings that are predicted to be generated and the drill fluids to be used. There is also a good understanding on the predicted fate of the discharges via drilling cuttings discharge modelling undertaken as part of the previously proposed Browse Development concepts. Drilling and completion activities required for the Proposal are expected to be broadly similar to that of the previously proposed development concepts. As such the previous modelling is considered representative of the Proposal and sufficient for assessing the potential impacts. • Undertaken hydrocarbon spill modelling to describe the dispersion and degradation characteristics of a range of hydrocarbon spill scenarios to inform the risk assessment and the development of mitigation measures.
Relevant Policy and Guidance	***EPA Policy and Guidance*** • Statement of Environmental Principles, Factors and Objectives (EPA 2016b) • Environmental Factor Guideline - Benthic Communities and Habitats (EPA 2016c) • Technical Guidance - Protection of Benthic Communities and Habitats (EPA, 2016d)

Table 16: Preliminary Key Environmental Factor and Required Work – Marine Environmental Quality

Marine Environmental Quality	
EPA Objective	To maintain the quality of water, sediment, and biota so that environmental values are protected (EPA, 2016f).
Relevant Activities	• Development drilling and completions • Installation of subsea umbilicals, risers and flowlines • Operation of wells and subsea infrastructure • Decommissioning • Support activities
Potential Impacts and Risks	Refer to **Table 7** and **Table 8** for the preliminary impact and risk assessments for the proposed Browse to NWS Project. In relation to the Proposal within State waters, the following impacts and potential risks are considered relevant to the Environmental Factor – Marine Environmental Quality: • IMP-5, IMP7a&b: Vessel discharges including treated sewage, drain discharges, cooling water and desalination brine: Discharges within regulatory limits from support vessels and the MODU leading to short term, localised reduction in water quality. • IMP-12 Drilling cuttings and fluids: Localised reduction in water quality and sediment quality as a result of the discharge of drill cuttings.

Marine Environmental Quality	
	- IMP-13 Subsea control fluid: Localised reduction in water quality and sediment quality as a result of the discharge of subsea control fluids. - Risk-9 Hydrocarbon spill: Long term contamination to marine water and sediments at levels above standards and on a regional scale. Considered highly unlikely to occur.
Required Work	Refer to **Table 12** for the full impact and risk assessment workplan. Refer to Section 3.8.8 for the scope of the proposed technical studies. In reference to the Environmental Factor – Marine Environmental Quality - Characterise the marine environmental quality in the area potentially impacted using existing survey data and literature. Woodside has a good understanding of the marine environment in the State waters within the Browse Development Area via numerous available studies and as such no further studies to characterise this marine environment is considered required. - Characterise discharge type that has the potential to impact on State coastal waters (e.g. vessel and MODU discharges, drill cuttings and fluids, produced water, cooling water, hydrotest fluid, subsea control fluids) in terms of volume, frequency, composition and ecotoxicity. - Present previously undertaken modelling or revised modelling where required as described in the workplan (Section 3.8.8) and describe the dilution and fate of the discharges to determine the spatial extent of potential impacts and appropriate mixing zones. - Based on characterisation of the existing marine environment and expected discharges and modelling, develop and present spatially proposed Environmental Quality Criteria (Environmental Quality Objectives and levels of ecological protection) for State waters within the Browse Development Area. - Outline a commitment to develop and implement a Marine Environmental Quality Plan (EQP) for the State coastal waters which identifies the Environmental Values to be protected and spatially defines the Environmental Quality Objectives and levels of ecological protection that Woodside aims to achieve in State waters. - Undertaken hydrocarbon spill modelling to describe the dispersion and degradation characteristics of a range of hydrocarbon spill scenarios to inform the risk assessment and the development of mitigation measures.
Relevant Policy and Guidance	***EPA Policy and Guidance*** - Statement of Environmental Principles, Factors and Objectives (EPA 2016c) - Environmental Factor Guideline – Marine Environmental Quality (EPA 2016e) - Technical Guidance – Protecting the Quality of Western Australia's Marine Environment (EPA 2016f)

Marine Environmental Quality	
	Other Policy and Guidance • Revised Australian and New Zealand Guidelines for Fresh and Marine Water Quality 2018 (ANZG (2018)

Table 17: Preliminary Key Environmental Factor and Required Work – Marine Fauna

Marine Fauna	
EPA Objective	To protect marine fauna so that biological diversity and ecological integrity are maintained (EPA, 2016f)
Relevant Activities	• Development drilling and completions • Installation of subsea umbilicals, risers and flowlines • Operation of wells and subsea infrastructure • Decommissioning • Support activities and helicopters
Potential Impacts and Risks	Refer to **Table 7** and **Table 8** for the preliminary impact and risk assessments for the proposed Browse to NWS Project. In relation to the proposal within State waters, the following impacts and potential risks are considered relevant to the Environmental Factor – Marine Fauna: • IMP-1 Underwater noise emissions: Impacts to sensitive marine fauna from noise emissions during drilling and completion of the wells, wellhead operations, piling and routine vessel and aviation operations • IMP-2 Light emissions: Impacts (attraction/repulsion, disorientation) on sensitive marine fauna as a result of light emissions from the MODU and support vessels • IMP-3a Physical presence of infrastructure during construction: Impacts to marine fauna as a result of unintentional interaction with support vessels. • IMP-3b Physical presence of infrastructure during operations: Impacts to marine fauna as a result of unintentional interaction with support vessels • IMP-12 Drilling cuttings and fluids: Localised reduction in water quality and sediment quality as a result of the discharge of drill cuttings and fluids with subsequent impacts to marine fauna. • IMP-15 Atmospheric Noise: Atmospheric noise generated by helicopter movements between the mainland and project area. • Risk-9 Hydrocarbon spill: Large scale mortality and injury to marine fauna on a regional scale. Considered highly unlikely to occur.
Required Work	Refer to **Table 12** for the full impact and risk assessment workplan. Refer to Section 3.8.8 for the scope of the proposed technical studies. In reference to the Environmental Factor – Marine Fauna: • Characterise the marine fauna in the area potentially impacted using

Marine Fauna	
	existing survey data and literature. Woodside generally has a good understanding of marine mammals that may occur in the Browse Development Area via a large number of surveys undertaken in relation to the previously proposed Browse Development concepts which have included habitat association surveys, long term sea noise logger deployment, aerial and vessel surveys and satellite tagging. • Characterise the predicted underwater noise emissions and potential impacts using existing and new modelling studies. • Characterise the predicted light emissions and potential impacts using existing modelling studies. Light modelling undertaken to support the FLNG EIS is considered representative of the Proposal facilities and as such no further modelling is considered necessary. • Predict the likely fate of discharged drill cuttings using existing data and modelling and assess impact on marine fauna. • Undertake a literature review on the impacts of electromagnetic emissions on marine fauna and utilise estimated direct electrical heating power demand to assess impacts. • Undertaken hydrocarbon spill modelling to describe the dispersion and degradation characteristics of a range of hydrocarbon spill scenarios to inform the risk assessment and the development of mitigation measures. This includes the modelling of a condensate spill which will be used to assess the risk to Scott Reef that such a spill would present (refer to Section 3.8.8).
Relevant Policy and Guidance	***EPA Policy and Guidance*** • Statement of Environmental Principles, Factors and Objectives (EPA 2016b) • Environmental Factor Guideline – Marine Environmental Quality (EPA 2016e) • Technical Guidance – Protecting the Quality of Western Australia's Marine Environment (EPA 2016f). ***Other Policy and Guidance*** • EPBC Act Policy Statement 2.1 – Interaction between Offshore Seismic Exploration and Whales (DEWHA 2008) • Conservation Management Plan for the Blue Whale - A Recovery Plan under the Environment Protection and Biodiversity Conservation Act 1999 (DoE 2015) • Conservation advice *Anous tenuirostris melanops* Australian lesser noddy (Threatened Species Scientific Committee 2015a) • Approved Conservation Advice for *Megaptera novaeangliae* (humpback whale) (Threatened Species Scientific Committee 2015b) • Recovery plan for marine turtles in Australia (Commonwealth of Australia

Marine Fauna	
	2017) - Conservation advice Rhincodon typus whale shark (Threatened Species Scientific Committee, 2015c) - Whale shark (*Rhyncodon typus*) recovery plan 2005- 2010 (DEH, 2005)

Table 18: Preliminary Key Environmental Factor and Required Work – Air Quality

Air Quality	
EPA Objective	To maintain air quality and minimise emissions so that environmental values are protected (EPA 2016i).
Relevant Activities	- Development drilling and completions - Installation of subsea umbilicals, risers and flowlines - Decommissioning - Support activities and helicopters.
Potential Impacts and Risks	Refer to **Table 7** and **Table 8** for the preliminary impact and risk assessments for the proposed Browse to NWS Project. In relation to the proposal within State waters, the following impacts and potential risks are considered relevant to the Environmental Factor – Air Quality including GHG emissions in State waters: - IMP-4a Gaseous emissions - Air Emissions: Impacts to local air quality
Required Work	Refer to **Table 12** for the full impact and risk assessment workplan. Refer to Section 3.8.8 for the scope of the proposed technical studies. In reference to the Environmental Factor – Air Quality: - Woodside has sufficient understanding of the characteristic of the Browse resource and the combustion requirements to extract, process and export the gas to accurately quantify gaseous. As such no further studies are considered required.
Relevant Policy and Guidance	***EPA Policy and Guidance*** - Statement of Environmental Principles, Factors and Objectives (EPA 2016c) - Environmental Factor Guideline: Air Quality (EPA 2016b) ***Other Policy and Guidance*** - Air Quality Modelling Guidance Notes 2006 (DoE 2006)

4.4 Other environmental factors or matters

No other environmental factors or matters were identified as being relevant to the Browse to State waters proposal.

Note: Woodside is aware that other factors or matters may be identified during the course of the environmental review that were not apparent when this EISG/ESD was prepared. If this situation arises, Woodside will consult with the EPA to determine whether these factors and/or matters are to be addressed in the EIS/ERD and if so, to what extent.

4.5 Stakeholder consultation

Woodside will consult with stakeholders who are affected by, or are interested in, the proposed Browse to NWS Project. These stakeholders include decision-making authorities, other relevant government agencies and authorities (local, state, and Commonwealth), the local community, local indigenous groups, academics, research authorities and environmental non-government organisations. The EIS/ERD will describe the consultation method adopted, existing stakeholder forums and skills and techniques used to ensure effective communication of the nature and detail of the State waters proposal. This will include the means used to identify concerns and to gauge and progress mitigation strategies.

Stakeholder consultation will include consultation with Department of Primary Industries and Regional Development in respect to the introduction of marine pests (IMPs) to ensure that the potential risk of IMPs to State waters is adequately assessed and managed.

The assessment documentation must provide details of the potential indirect impacts of the proposed action on the (Indigenous rock art) values of the Dampier Archipelago (including the Burrup Peninsula) National Heritage Place, and the extent to which these values may potentially be impacted by the proposed action following any planned mitigations.

Woodside will document all relevant stakeholder consultation information in the EIS/ERD.

4.6 Decision-making authorities

The EPA has identified the decision-making authorities (listed in **Table 19**) for the proposal. Additional decision-making authorities may be identified during the assessment.

Table 19: Decision-making Authorities

Decision-making Authority	Relevant Western Australian Legislation
Minister for Mines and Petroleum	*Petroleum (Submerged Lands) Act 1982*
Chief Executive Officer, Department of Water and Environmental Regulation	*Environmental Protection Act 1986*
Chief Dangerous Goods Officer, Department of Mines, Industry Regulation and Safety	*Dangerous Goods Safety Act 2004*

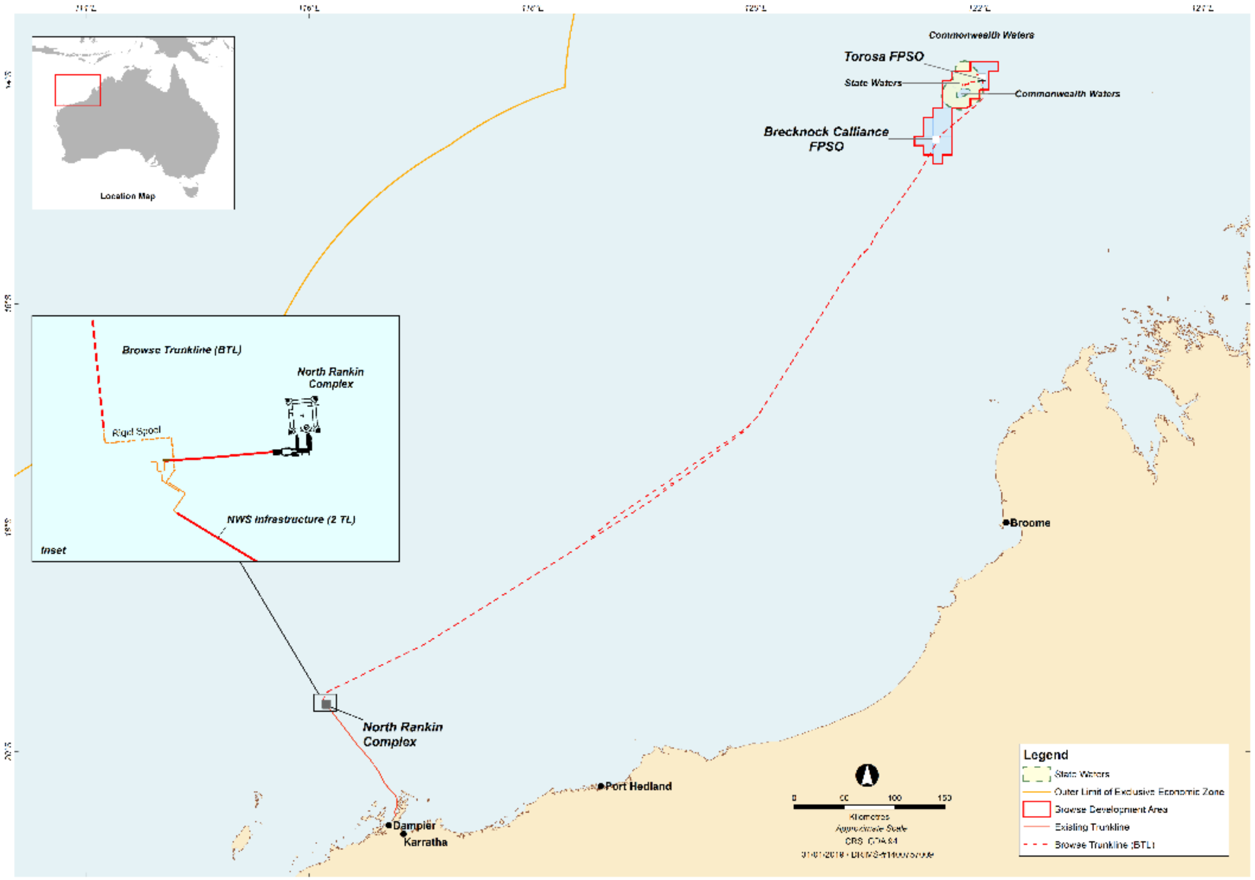

Figure 2 Indicative Browse Trunkline (BTL) route. Note alternative routes mid BTL are being assessed.

7. APPENDIX A – COMMONWEALTH GUIDANCE FOR GREENHOUSE GAS EMISSIONS

The proponent is required to provide transparent and accurate information to support decision making. This document is intended to assist the proponent to structure the discussion of the greenhouse implications of their development proposal.

To aid assessment of greenhouse gas (GHG) emissions resulting from the Browse to NWS Project, the following information is required:

1. Inventory of annual emissions

Provide data on estimated maximum annual emissions of the greenhouse gases defined in the *National Greenhouse and Energy Reporting Act 2007* (Cth): from within the development area; and, to the extent it can be predicted, from elsewhere as it is transported, processed (liquefied) and combusted, in Australia or overseas.

The inventory should include: an estimate of emissions on a gas by gas basis; a summary table of emissions on a gas by gas basis; a summary table listing emissions on a carbon dioxide equivalent basis; and a table which includes gross emissions, emission reduction due to both offsets and mitigation, and net emissions.

As far as is practicable an inventory of cumulative emissions should be included with regards to known potential future expansions or developments by Woodside and other proponents in the vicinity of the development.

In addition, estimates of emissions per year over the life of the project (in addition to the existing requirement around maximum emissions) and estimate of emissions intensity of production (ie emissions divided by production) over the life of the project should be provided.

2. Mitigation

The proponent must include a full description of mitigation measures, including analysis of a full range of alternatives to the proposed project. This should include methods by which GHG emissions could be mitigated, including:

a) analysis of the likely GHG reductions as a result of mitigation efforts to the same level of detail and approach as described in the ‘Inventory of annual emissions’ above;

b) analysis of costs, both financial and output related, of mitigation; and

c) identification of any relevant voluntary partnerships between government and the proponent, and their links to mitigation.

3. Method

The proponent must identify, in a transparent manner, the *National Greenhouse and Energy Reporting (Measurement) Determination 2008* method used in making the estimate. If no methodology exists, a methodology reflecting the principles of the NGER will be developed and agreed by the proponent and the Department.

4. Supporting Data

The following supporting data must be provided:

a) the proponent must provide details on the emission factors used and activity data used, and

b) the project’s emission factors and activity data need to be compared with similar projects, including both Australian and international best practice. This analysis should include projects that use alternative fuel sources, processes, and technologies.

CHAPTER 10, APPENDIX B

PROPOSED BROWSE TO NWS PROJECT STATE ERD

STATE ERD

1. PREAMBLE

This State Environmental Review Document (ERD) is an addendum to the draft Environmental Impact Statement (EIS)/ERD for the proposed Browse to North West Shelf (NWS) Project and has been prepared to provide proposed details and assessment conclusions specific to the State components of the proposed Browse to NWS Project (Proposal). The majority of the proposed Browse to NWS Project is located outside State jurisdiction. Most notably, the Floating Production Storage and Offloading facilities (FPSOs) and the entire length of the Browse Trunkline (BTL) are located in Commonwealth waters. However, a portion of the subsea wells and gathering system for the Torosa FPSO extend into State waters.

The draft EIS/ERD provides a 'whole of project' assessment as per the approved EIS Guidelines/ Environmental Scoping Document (EISG/ESD). This document has been prepared to further assist readers of the draft EIS/ERD to clearly identify the activities, aspects, receptors, predicted impacts and potential risks that are applicable to the assessment of the State aspects of the Proposal under the *WA Environmental Protection Act 1986* only.

This State ERD focuses on State aspects of the Proposal and therefore does not repeat all information on the proposed Browse to NWS Project. This State ERD references the reader back to the draft EIS/ERD where relevant. As such, this State ERD is to be read in conjunction with the draft EIS/ERD. It should be noted that, unless stated otherwise, where content within the draft EIS/ERD is referenced within this State ERD, content in the draft EIS/ERD applies equally to State and Commonwealth jurisdictions.

2. INVITATION TO MAKE A SUBMISSION

The Western Australian (WA) Environmental Protection Authority (EPA) invites people to make a submission on the environmental review for the proposed Browse to NWS Project (Proposal).

Woodside Energy Ltd, as operator for and on behalf of the Browse Joint Venture, proposes to develop and operate the proposed Browse to NWS Project. This Environmental Review Document (ERD) has been prepared in accordance with the EPA's Procedures Manual (Part IV Divisions 1 and 2). The ERD is the report through which the proponent describes the Proposal, assesses and documents its likely effects on the environment.

The ERD is available for a public review period of 8 weeks from 18 December 2019, closing on 12 February 2020.

Information on the Proposal from the public may assist the EPA to prepare an assessment report in which it will make recommendations on the Proposal to the Minister for Environment.

Why write a submission?

The EPA seeks information that will inform the EPA's consideration of the likely effect of the Proposal, if implemented, on the environment. This may include relevant new information that is not in the ERD, such as alternative courses of action or approaches.

In preparing its assessment report for the Minister for Environment, the EPA will consider the information in submissions, the proponent's responses and other relevant information.

Submissions will be treated as public documents unless provided and received in confidence, subject to the requirements of the *Freedom of Information Act 1992* (WA).

Why not join a group?

It may be worthwhile joining a group or other groups interested in making a submission on similar issues. Joint submissions may help to reduce the workload for an individual or group. If you form a small group (up to 10 people) please indicate all the names of the participants. If your group is larger, please indicate how many people your submission represents.

Developing a submission

You may agree or disagree with, or comment on information in the ERD.

When making comments on specific elements in the ERD:

+ clearly state your point of view and give reasons for your conclusions
+ reference the source of your information, where applicable
+ suggest alternatives to improve the outcomes on the environment.

What to include in your submission

Include the following in your submission to make it easier for the EPA to consider your submission:

- your contact details – name and address
- date of your submission
- whether you want your contact details to be confidential
- summary of your submission, if your submission is long
- list points so that issues raised are clear, preferably by environmental factor
- refer each point to the page, section and, if possible, paragraph of the ERD
- attach any reference material, if applicable. Make sure your information is accurate.

The closing date for public submissions is: 12 February 2020

The EPA prefers submissions to be made electronically via the EPA's Consultation Hub at https://consultation.epa.wa.gov.au

Alternatively, submissions can be:

- posted to: Chairman, Environmental Protection Authority, Locked Bag 10, Joondalup DC WA 6919, or
- delivered to: The Environmental Protection Authority, 8 Division Terrace, Joondalup WA 6027.

If you have any questions on how to make a submission, please contact the EPA Services at the Department of Water and Environmental Regulation (DWER) on (08) 6364 7000.

3. SCOPING CHECKLIST

Table 3-1 presents the completed scoping checklist which identifies the required work (as per the approved Environmental Scoping Document (ESD)) and reference to the location in the draft EIS/ERD and this State ERD where the requirement has been met.

Table 3-1 Scoping Checklist

Task No.	Required Work	Section and Page No.
Benthic Communities and Habitats		
1.	Determination of predicted temporary and permanent seabed disturbance within State waters.	Section 8.3.4.2 (pg. 915); Section 6.3.1 of the draft EIS/ERD
2.	Characterise the benthic habitats in the area potentially impacted using existing survey data and literature, including the preparation of habitat maps with demonstrated ground truthing for areas where proposed infrastructure will be installed on the seabed within State waters. Woodside has a good understanding of the benthic habitats expected to be disturbed within State waters and, as such, no further studies to characterise these benthic habitats is considered required.	Section 8.3.3 (pg. 912); Section 5.3.1 of the draft EIS/ERD
3.	Where significant benthic communities are identified in areas where infrastructure will be installed on the seabed, identify an appropriate Local Assessment Unit and assess cumulative loss of benthic communities and habitats in accordance with EPA's technical guidance.	Section 8.3.7 (pg. 922)

Task No.	Required Work	Section and Page No.
4.	Predict the likely fate of discharged drill cuttings using existing data and modelling and assess impact on benthic habitats. Woodside has a good understanding of the quantity and nature of the drill cuttings that are predicted to be generated and the drill fluids to be used. There is also a good understanding on the predicted fate of the discharges via drilling cuttings discharge modelling undertaken as part of the previously proposed Browse Development concepts. Drilling and completion activities required for the Proposal are expected to be broadly similar to that of the previously proposed development concepts. As such, the previous modelling is considered representative of the Proposal and sufficient for assessing the potential impacts.	Section 8.3.4.9 (pg. 917); Section 6.3.15 of the draft EIS/ERD
5.	Undertake hydrocarbon spill modelling to describe the dispersion and degradation characteristics of a range of hydrocarbon spill scenarios to inform the risk assessment and the development of mitigation measures.	Section 8.3.4.15 (pg. 920); Section 6.3.21 of the draft EIS/ERD
Marine Environmental Quality		
6.	Characterise the marine environmental quality in the area potentially impacted using existing survey data and literature. Woodside has a good understanding of the marine environment in the State waters within the Browse Development Area via numerous available studies and, as such, no further studies to characterise this marine environment is considered required.	Section 8.2.3 (pg. 892); Sections 5.2.9, 5.2.10, 5.3.1, 5.3.2, 5.3.3.3 and 5.4.2.2 of the draft EIS/ERD
7.	Characterise discharge type that has the potential to impact on State waters (e.g. vessel and MODU discharges, drill cuttings and fluids, produced water, cooling water, hydrotest fluid, subsea control fluids) in terms of volume, frequency, composition and ecotoxicity.	Section 8.2.4 (pg. 892); Sections 6.3.9, 6.3.10, 6.3.11, 6.3.12, 6.3.13, 6.3.15, 6.3.16, 6.3.17 of the draft EIS/ERD
8.	Present previously undertaken modelling or revised modelling where required as described in the workplan (Section 3.8.8 of the EISG/ESD) and describe the dilution and fate of the discharges to determine the spatial extent of potential impacts and appropriate mixing zones.	Section 8.2.4 (pg. 892); Sections 6.3.12, 6.3.13, 6.3.15, 6.3.17 of the draft EIS/ERD
9.	Based on characterisation of the existing marine environment and expected discharges and modelling, develop and present spatially proposed Environmental Quality Criteria (Environmental Quality Objectives and levels of ecological protection) for State waters within the Browse Development Area.	Section 8.2.6 (pg. 906);
10.	Outline a commitment to develop and implement a Marine Environmental Quality Management Plan (EQMP) for the State waters which identifies the Environmental Values to be protected and spatially defines the Environmental Quality Objectives and levels of ecological protection that Woodside aims to achieve in State waters.	Section 8.2.6 (pg.906);
11.	Undertake hydrocarbon spill modelling to describe the dispersion and degradation characteristics of a range of hydrocarbon spill scenarios to inform the risk assessment and the development of mitigation measures.	Section 8.3.4.15 (pg. 920); Section 6.3.21 of the draft EIS/ERD

Task No.	Required Work	Section and Page No.
Marine Fauna		
12.	Characterise the marine fauna in the area potentially impacted using existing survey data and literature. Woodside generally has a good understanding of marine mammals that may occur in the Browse Development Area via a large number of surveys undertaken in relation to the previously proposed Browse Development concepts which have included habitat association surveys, long-term sea noise logger deployment, aerial and vessel surveys and satellite tagging.	**Section 8.4.3** (pg. 924); **Section 5.3.2** of the draft EIS/ERD
13.	Characterise the predicted underwater noise emissions and potential impacts using existing and new modelling studies.	**Section 8.4.4.6** (pg. 933); **Section 6.3.8** of the draft EIS/ERD
14.	Characterise the predicted light emissions and potential impacts using existing modelling studies. Light modelling undertaken to support the FLNG draft EIS (EPBC 2013/7079 is considered representative of the Proposal facilities and, as such, no further modelling is considered necessary.	**Section 8.4.4.2** (pg. 928); **Section 6.3.3** of the draft EIS/ERD
15.	Predict the likely fate of discharged drill cuttings using existing data and modelling and assess impact on marine fauna.	**Section 8.4.4.11** (pg. 935); **Section 6.3.15** of the draft EIS/ERD
16.	Undertake a literature review on the impacts of electromagnetic emissions on marine fauna and utilise estimated direct electrical heating power demand to assess impacts.	**Section 8.4.4.3** (pg. 931)
17.	Undertake hydrocarbon spill modelling to describe the dispersion and degradation characteristics of a range of hydrocarbon spill scenarios to inform the risk assessment and the development of mitigation measures. This includes the modelling of a condensate spill which will be used to assess the risk to Scott Reef that such a spill would present.	**Section 8.4.4.18** (pg. 940); **Section 6.3.21** of the draft EIS/ERD.
Air Quality		
18.	Woodside has sufficient understanding of the characteristics of the Browse resource and the combustion requirements to extract, process and export the gas to accurately quantify gaseous emissions. As such, no further studies are considered required.	**Section 8.5** (pg. 942); **Section 6.3.5**, **6.3.6** and **Chapter 7** of the draft EIS/ERD.

4. INTRODUCTION

This State ERD is an addendum to the draft EIS/ERD for the proposed Browse to NWS Project to satisfy the requirements of the:

- Environmental Impact Assessment (Part IV Divisions 1 and 2) Administrative Procedures 2016 (EPA, 2016)
- EPA's Instructions on how to prepare an Environmental Review Document (EPA, 2018a).

It has been prepared to assist the reader of the draft EIS/ERD to clearly identify the activities, aspects, receptors, predicted impacts and potential risks that are applicable to the assessment of the Proposal under the WA *Environmental Protection Act 1986* only.

The scope of the Proposal that is the subject of this State ERD is limited to the proposed activities within the State Proposal Area (**Section 5.3.1**) and vessel and helicopter movements occurring within State waters between the State Proposal Area and the potential supply chain and logistics support locations.

4.1 Proponent

Please refer to **Section 2.3** of the draft EIS/ERD for proponent details.

4.2 Environmental Impact Assessment Process

Please refer to **Section 2.9** of the draft EIS/ERD for the assessment process for the proposed Browse to NWS Project, including the Proposal.

4.3 Other Approvals and Regulation

4.3.1 Titles

The Browse Joint Venture (BJV) holds seven petroleum retention leases. Five of the leases (WA 28 R, WA-29-R, WA-30-R, WA-31-R and WA-32-R) are located in Commonwealth waters and are governed under the *Offshore Petroleum and Greenhouse Gas Storage Act 2006* (Cth) (OPGGSA). The remaining two leases (TR/5 and R2) are governed under State legislation, the *Petroleum (Submerged Lands) Act 1982* (WA) (PSLA) and the *Petroleum and Geothermal Energy Resources Act 1967* (WA).

4.3.2 Decision Making Authorities

The decision making authorities for the Proposal are listed in **Table 4-1.**

Table 4-1 Decision Making Authorities

Decision Making Authority	Relevant Western Australian Legislation
Minister for Mines and Petroleum	*Petroleum (Submerged Lands) Act* 1982 and the *Petroleum and Geothermal Energy Resources Act* 1967 (WA)
Chief Executive Officer, Department of Water and Environmental Regulation	*Environmental Protection Act* 1986
Chief Dangerous Goods Officer, Department of Mines, Industry Regulation and Safety	*Dangerous Goods Safety Act* 2004

4.3.3 Other Approvals

Table 4-2 summarises the other approvals and regulations that apply to the Proposal.

Table 4-2 Other Approvals

Proposed Activities	Land tenure/access	Type of approval	Legislation regulating the activity
Subsea infrastructure development and operation	Petroleum titles	Environment Plans and Oil Spill Contingency Plans	*Petroleum (Submerged Lands) Act 1982* (WA) and associated regulations

5. THE PROPOSAL

5.1 Background

The Proposal was referred to the EPA under the *Environmental Protection Act* 1986 (EP Act) in October 2018. On 22 January 2019, the EPA determined the Proposal required assessment under Section 29 of the EP Act and set a Public Environmental Review (PER) level of assessment. The determination identified these EPA Environmental Factors as being relevant for the Proposal:

- Marine Environmental Quality
- Benthic Communities and Habitats
- Marine Fauna
- Air Quality.

The draft EIS/ERD conforms with the EIS Guidelines/ Environmental Scoping Document (EISG/ESD) approved by the DoEE on 5 July 2019 and EPA on 4 July 2019, respectively (**Chapter 10, Appendix A** of the draft EIS/ ERD). The EISG/ESD was made publicly available on the 8 July 2019.

The proposal is similar to the previously referred 'Torosa Subsea Development Proposal' that resulted in a 'Not Assessed – Public Advice Given' decision by the EPA in 2015 (CMS14397).

The proposed Browse to NWS Project continues to be subject to detailed design and refinement. Key modifications that have occurred since the referral of the Proposal and approval of the EISG/ESD include:

- an increase in the number of wells within State waters from up to approximately 21 to up to approximately 24
- a minor increase in seabed infrastructure related to the higher well count and design refinement.

Refer to **Chapter 2** of the draft EIS/ERD for an overview of the proposed Browse to NWS Project and background information, including details of the assessment process (**Section 2.9** of the draft EIS/ERD), the Browse resources, the proponent, the project objectives, current status and relationship with other developments.

5.2 Justification

Please refer to **Section 2.8** of the draft EIS/ERD for the development justification.

5.3 Proposal Description

This section provides an overview of the State components of the Proposed Browse to NWS Project Proposal. A full description of the proposed Browse to NWS Project is provided in **Chapter 3** of the draft EIS/ERD.

5.3.1 State Proposal Area

As described in **Chapter 2** of the draft EIS/ERD, the overall Project Area (encompassing both State and Commonwealth components) comprises:

- the proposed Browse Development Area (in which the Brecknock, Calliance, and Torosa fields, the FPSO facilities and the subsea production systems, including wells, will be located) (**Figure 2-1** of the draft EIS/ERD)
- the pipeline corridor within which the proposed BTL and inter-field spur line will be located (**Figure 2-2** of the draft EIS/ERD).

The State Proposal Area, which is the subject of the assessment under the EP Act, is located within the Browse Development Area and comprises all areas above the low water line (based on mean low water springs (MLWS)) and all waters within 3 nm of the low water line, as shown in **Figure 5-1**.

It should be noted that, as detailed in **Chapter 4**, the scope of this State ERD includes vessel and helicopter movements occurring within State waters outside of the State Proposal Area.

5.3.2 Overview

Activities in the State Proposal Area comprise a small subset of infrastructure and activities of the proposed Browse to NWS Project. Within State jurisdiction, activities include the development of up to an estimated 24 wells and associated subsea infrastructure targeting the hydrocarbon resources within the Torosa reservoir. The remaining facilities and infrastructure will be located in Commonwealth waters and are outside the scope of this State ERD. Extracted hydrocarbons will be transferred via subsea infrastructure, including Christmas trees, manifolds and flowlines, to the Torosa FPSO facility, located in Commonwealth waters.

The highest intensity of activities within the State Proposal Area is likely to occur during the drilling and completion activities, installation activities and future decommissioning phases. During this time, a mobile offshore drilling unit (MODU) and approximately ten vessels may be present. As all permanent infrastructure within the State Proposal Area is subsea, the operation of the wells will be controlled remotely via the FPSO facilities that are located in Commonwealth waters. Outside of drilling and completion and installation periods, surface activities in the State Proposal Area will comprise periodic inspection, maintenance and repair activities involving one or two vessels and later phase well construction and decommissioning (including well plug and abandonment). **Table 5-1** provides a summary of the Proposal.

Table 5-1 Summary of the Proposal

Proposal Summary	
Proposal Title	Proposed Browse to NWS Project (State component)
Proponent Name	Woodside Energy Ltd, as Operator for and on behalf of the Browse Joint Venture
Short Description	Drilling and completion, subsea installation, commissioning, operation, inspection, maintenance and repair and decommissioning of subsea wells and associated subsea infrastructure located in Western Australian State waters, to extract hydrocarbons from the Torosa reservoir, located approximately 425 km north of Broome and approximately 290 km off the Kimberley coast.

Table 5-2 Location and proposed extent of physical and operational elements of the Proposal

Element	**Description**	**Proposed Authorised Extent**
Physical Elements		
Drilling and completion activities of up to approximately 24 wells	Installation and physical presence of infrastructure within indicative field layout as per **Figure 5-1**.	Approximately 0.31 km^2 of direct seabed disturbance (including 25% contingency).
Associated subsea infrastructure (Christmas trees, manifolds, flowlines, and umbilicals)		
Temporary mooring of MODU		
Seabed preparation and flowline stabilisation		
Operational Elements		
Water supply (installation vessels, Inspection, Maintenance and Repair (IMR) vessels, MODUs and project vessels)	Water requirements sourced either from seawater (reverse osmosis plant) or loaded at port.	Limited water requirements to support drilling and completion activities, subsea installation activities (e.g. potential hydrotest), vessel and MODU water needs and potentially also for decommissioning activities.
Power supply (installation vessels, IMR vessels, MODUs and project vessels)	Power generated on board vessels and MODU.	As required for operations and safety.
Vessel discharges (installation vessels, IMR vessels, MODU, and project vessels).	Discharges from vessels and MODU include treated sewage, drain waters, cooling water, sullage, putrescible organic waste and desalination brine.	Limited volumes discharged in accordance with International Convention for the Prevention of Pollution from Ships MARPOL 73/78 Annex I, as applied in Australia under the Commonwealth *Protection of the Sea (Prevention of Pollution from Ships) Act 1983* (Part II Prevention of pollution from oil); Marine Orders 91 (Marine pollution prevention – Oil) 2014 as applicable to vessel class; *Pollution of Waters by Oil and Noxious Substance Act 1986.*
Drill cuttings and fluid discharges	Drill cuttings and drilling fluids.	Approximately 850 m^3 of cuttings per well, with up to approximately 24 wells to be developed in the State Proposal Area. Approximately 100-130 m^3 well discharge fluid per well during well unloading.

Element	Description	Proposed Authorised Extent
Hydrotest fluid discharges	Hydrotest fluids discharged at the seabed during integrity testing of the subsea infrastructure.	Oneoff discharges of up to approximately 950 m^3 of hydrotest fluid for the TRE flowline and up to approximately 250 m^3 at the TRF flowline.
Produced water	Low volumes of water that occurs naturally within the hydrocarbon-bearing geological formations.	Small volumes of formation water may result during well unloading activities by the MODU. These will be discharged directly from the MODU.
Subsea control fluid discharge	Control fluid discharged at the Christmas trees to maintain valve functionality.	Intermittent discharge of waterbased hydraulic control fluid when subsea valves are actuated (~0.1 L). Maximum volume of control fluid that will be released to the marine environment per manifold is 1,900 L per year of water based fluid containing approximately ~3% active ingredient (40–68 L of control fluid additive).
Underwater noise emissions	Underwater noise: + generated during drilling, completion and installation activities (including vessel movements using Dynamic Positioning (DP), vertical seismic profiling (VSP) and distributed acoustic sensing (DAS) + generated from subsea infrastructure during operations + from piling activities for mooring installation for the MODU (note that this is unlikely to be required) + from installation vessels, IMR vessels, MODUs and project vessels + from helicopter movements from the MODU + from IMR activities.	Noise related behavioural disturbance radius of up to approximately 10.5 km around drilling and installation activities. Noise related behavioural disturbance radius of up to approximately 500 m around subsea infrastructure during operations.
Light emissions – operational lighting	Artificial light emitted by installation vessels, IMR vessels, MODUs and project vessels.	Limited to functional lighting at levels that provide a safe working environment for personnel.
Light emissions – flaring	Intermittent flaring from the MODU during well unloading. This occurs only during well installation or intervention for repairs.	
Air emissions – offshore activities	Air emissions resulting from power generation on project vessels and MODU.	

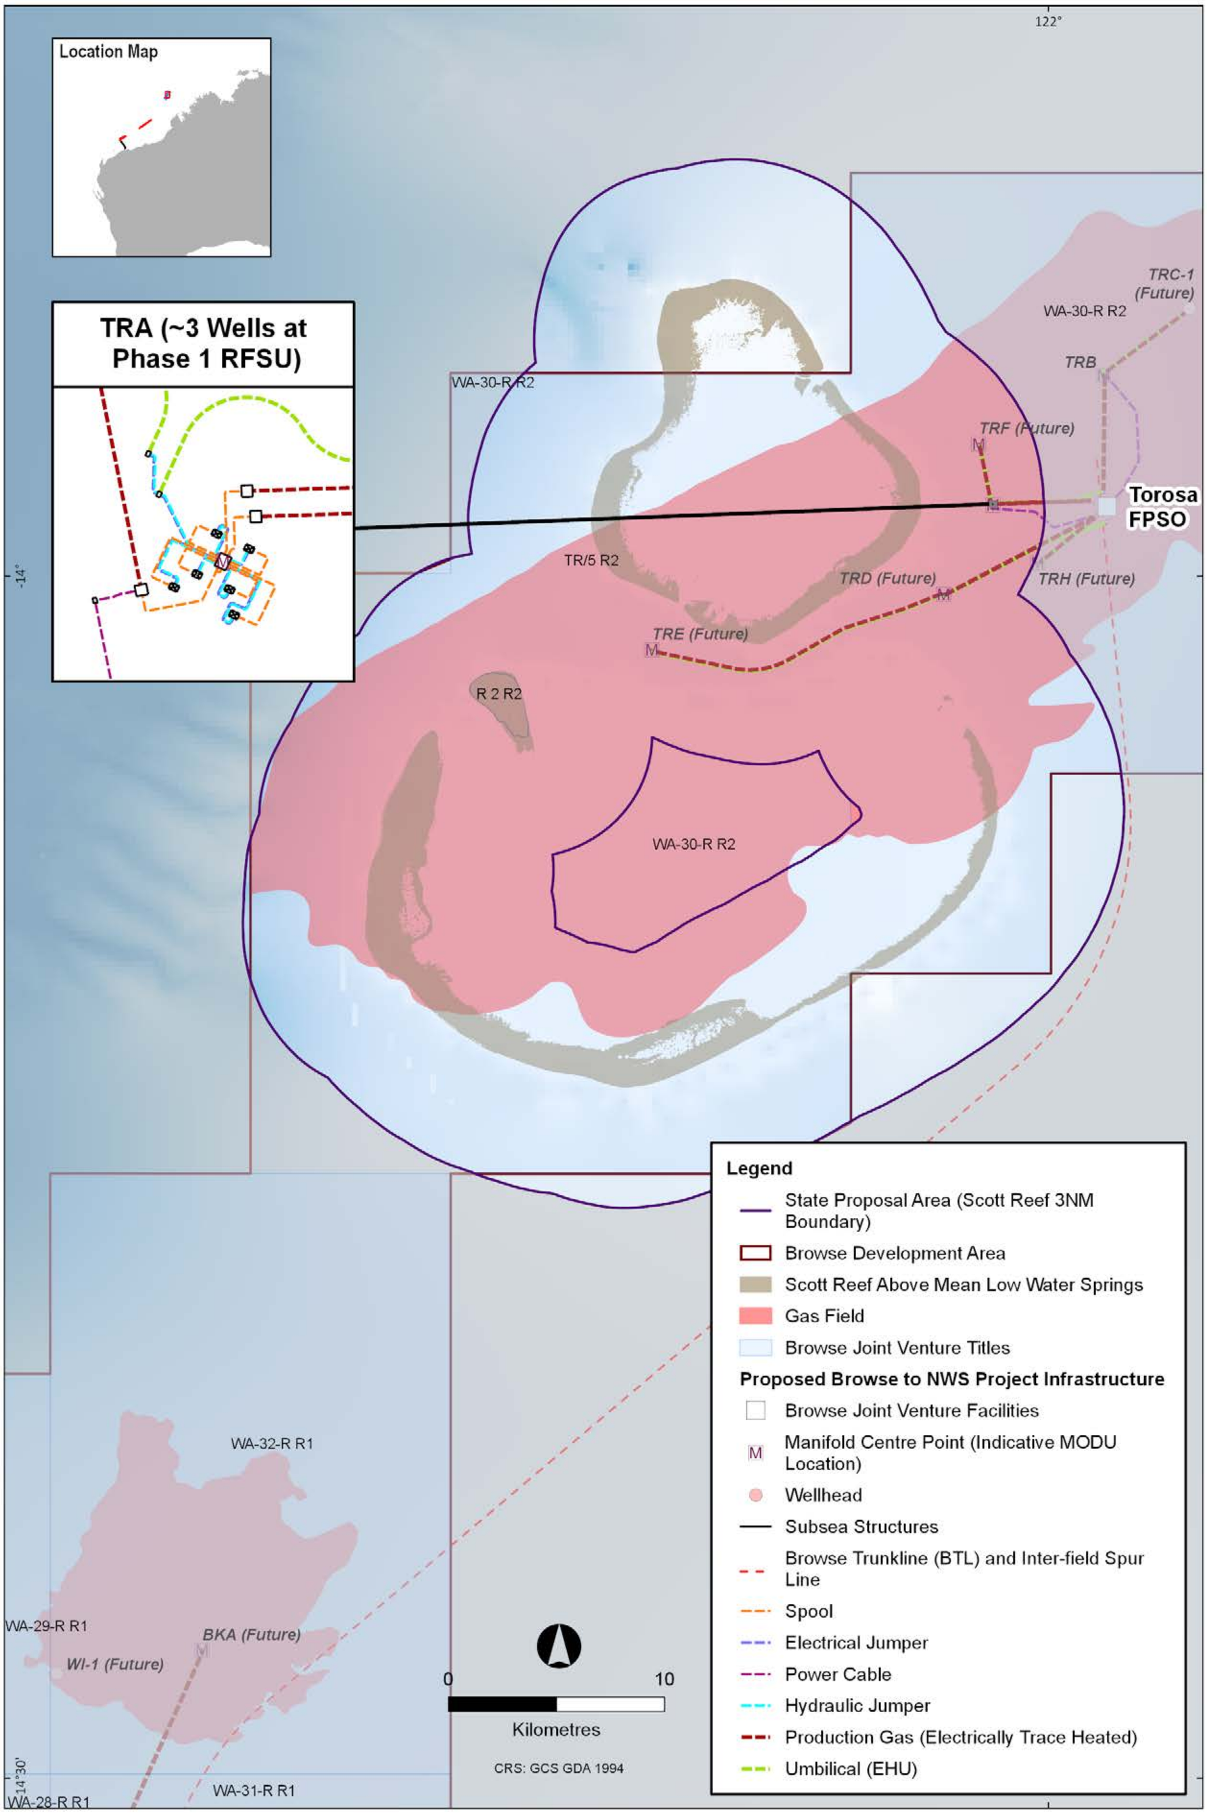

Figure 5-1 State Proposal Area

5.3.3 Project Infrastructure

Project infrastructure within the State Proposal Area is proposed to comprise the following:

- 24 production wells
- subsea infrastructure
- temporary moorings for MODU anchoring.

It should be noted that the BTL, inter-field spur line and FPSO facilities will be located entirely in Commonwealth waters.

Production wells
It is anticipated the proposed Browse to NWS Project will require drilling and completion of up to 24 production wells in State waters at the Torosa reservoir over the life of the proposed Browse to NWS Project. This includes the drilling and completion of approximately three wells at the TRA drill centre for Phase 1 Ready for Start Up (RFSU). The remaining 30 production wells of the Browse to NWS Project will be located in Commonwealth waters (including five at the Torosa reservoir and 25 at the Brecknock and Calliance reservoirs).

A wellhead will be installed at the top of each well. The wellhead will hold the production well casing and will enable installation of the Christmas tree, complete with well control facilities. Christmas trees are steel structures with various valves and are used to:

- control production, whereby hydraulically controlled valves on the Christmas trees are used to control flow rates and provide a well shut-off mechanism
- manage chemical injection.

Surface controlled subsurface safety valves will be installed in the wells.

To optimise the layout of the subsea infrastructure, production wells will be arranged around drill centres (a cluster of wells around a central manifold) with up to four drill centres located within the State Proposal Area. Only one drill centre (TRA) will be installed in the State Proposal Area prior to start-up of the Torosa FPSO Facility – the residual will be installed in later years. The number and location of these wells and drill centres will depend on reservoir target areas, seabed bathymetry and features to optimise reservoir recovery. A notional field layout is provided in Figure 5-1.

Subsea infrastructure
The wells at each drill centre will be connected to manifolds by well jumpers (a specially-designed piece of pipe used to transport production fluid between components of the subsea infrastructure) to allow reservoir fluids to be carried from the wells to the manifolds. The manifolds will connect the wells to corrosion resistant alloy clad (or lined) flowlines that will be routed back to the FPSOs, located in Commonwealth waters. An example of subsea infrastructure for illustrative purposes is provided in Figure 3-1 of the draft EIS/ERD.

Subsea infrastructure will be powered, monitored and controlled from the FPSO facilities using a network of electro-hydraulic control umbilicals and subsea distribution units. Each drill centre will be serviced by an electro-hydraulic umbilical, which will follow a similar alignment as the infield flowlines. Some umbilicals may be integrated within the production flowline bundle. Umbilicals will also be tied back to the FPSO facilities (in Commonwealth waters) using a system of flexible risers.

Other subsea infrastructure may include pile installation and temporary mooring lines for MODU anchoring.

5.3.4 Development Activities

Development activities within the State Proposal Area will include:

- pile installation
- development drilling and completions
- subsea umbilicals, risers and flowlines (SURF) installation and commissioning.

Pile installation
Pile installation may be required within State waters for temporary mooring of the MODUs. Data from the surveys undertaken by Woodside in 2014 has been analysed and demonstrates suction piling for moorings is feasible and will be the most likely option for pile installation.

Suction piles are installed by gently lowering the pile onto the seabed and using gravity to lower the pile into the soft substrate. Installation is completed by pumping out the entrapped water inside the pile, with the resulting differential pressure driving the pile into the seabed.

Should alternate piling methods be selected, options include drilling and cementing or impact piling, which involves the application of force to drive the pile into the seabed.

Development drilling and completions

The proposed Browse to NWS Project will require the drilling of up to 24 production wells within State waters. It is anticipated the drilling and completion activities will be completed in multiple phases. The first phase will be drilling and completion of approximately three wells at the TRA drill centre to achieve RFSU, with subsequent phases of drilling and completion of additional wells undertaken over the life of the Proposal to optimise reservoir recovery (Figure 5-1). The drilling and completions process will not differ between wells in State and Commonwealth waters and is described in detail in Section 3.7.2 of the draft EIS/ERD.

Subsea Umbilicals, Risers and Flowlines (SURF) installation and commissioning

The process for the installation and commissioning of the SURF infrastructure, including site preparation, is described in detail in Section 3.7.3 of the draft EIS/ERD.

5.3.5 Operations

Activities within the State Proposal Area during operations will be limited to:

- hydrocarbon extraction
- inspection, maintenance and repair (IMR) activities.

Hydrocarbon extraction

During operations, hydrocarbons extracted from the reservoirs will flow via the Christmas trees and manifolds through the flowlines and risers to the FPSO facilities in Commonwealth waters. The flow rate of hydrocarbons will be controlled by subsea choke valves at the Christmas trees. Subsea hydraulic control fluids will be used to operate subsea valves. Hydrocarbon extraction including the potential use of distributed acoustic sensing (DAS) surveys is described in Section 3.7.6.1 of the draft EIS/ERD. Note that processing of the gas and condensate on the FPSO facilities and subsequent condensate offload and gas export will occur in Commonwealth waters.

Inspection, maintenance and repair (IMR)

The subsea infrastructure will be designed to require only minor degrees of intervention. Inspection and maintenance will be undertaken to ensure the integrity of the infrastructure and identify any problems before they present a risk of loss of containment. Intervention may be required to repair identified problems. A detailed description of the planned IMR activities is provided in Section 3.7.7 of the draft EIS/ERD.

5.3.6 Decommissioning

At the end of the proposed Browse to NWS Project life, the infrastructure will be decommissioned in accordance with good oilfield practice and relevant legislation and practice at the time. This is likely to include well suspension, plugging and abandoning wells and removing the subsea infrastructure. All infrastructure installed above the seabed will be designed to allow removal.

Given the expected life of the project, the decommissioning of the proposed Browse to NWS Project is not likely for many years. Given the possible improvements in technology that may occur between now and the time of decommissioning, it is not possible to fully scope the decommissioning strategy that will be employed at that time however all infrastructure above the seabed has been designed to allow removal. The strategy demonstrated through activity-specific Environment Plans will be developed in consultation with the EPA and other stakeholders closer to the time (Table 4-2).

5.3.7 Support Activities and Infrastructure

5.3.7.1 Logistics support

The proposed Browse to NWS Project will require supply chain and logistics support during construction and operations, as described in Section 3.7.9 of the draft EIS/ERD.

Requirements for supply chain and logistics support for the proposed Browse to NWS Project may include:

- port access for supply and support vessels to transfer people, equipment, materials and waste to and from the Project Area
- airport access for fixed-wing aircraft and helicopters to transfer people and supplies to and from the Project Area
- search and rescue capabilities
- onshore support for receiving, storing, and distributing materials and equipment.

The proposed Browse to NWS Project is not dependent on the development of new onshore supporting infrastructure to proceed. Supply chain and logistics support locations that have existing services and infrastructure for ongoing regular support over the whole life of the proposed Browse to NWS Project are being considered, with the assessment and selection focused on using supply chain services and infrastructure within WA.

Potential supply chain and logistics support locations in Australia include:

- Broome
- Djarindjin
- Dampier/Karratha
- Exmouth
- Perth.

Facilities in Broome include the Port of Broome, which is the main deep water port servicing the Kimberley region. The port supports livestock export, offshore oil and gas, supply vessels, pearling, fishing charter boats, cruise liners and is the main fuel and container receiving point for the Kimberley. Facilities at the port include an outer berth, two inner berths, fuel and potable water distribution facilities, a laydown area, lighting suitable for night work and a slipway. Other facilities include the Broome International Airport which is located in Broome and includes a runway for fixed wing operations and a heliport which opened in 2008. A helipad is also available on site with space for four larger helicopters and 10 additional helicopter parking positions are available near the airport.

The King Bay Supply Base is located in the Port of Dampier and is operated by Woodside (Woodside 2014). The facility is suitable for a wide range of vessels varying in size and configuration such as harbour tugs, supply vessels, crew and utility vessels and transportation/heavy lift vessels.

Facilities in Djarindjin include a fixed and rotary wing aviation base which supports existing offshore oil and gas facility crew change operations.

As the proposed Browse to NWS Project will be using existing supply and logistics services and infrastructure which are managed by third parties, such services and infrastructure are not considered further as part of this assessment. The scope of this assessment is limited to vessel and helicopter movements between the State Project Area and the potential supply chain and logistics support locations. Any activity at supply chain and logistics support locations is outside the scope of this assessment.

In addition, there may be a requirement to conduct short term, discrete logistical support activities from time to time at various port and airport locations along the coast of WA, Australia and internationally to support activities throughout the life of the proposed Browse to NWS Project. These activities are likely to be consistent with general shipping activities.

5.3.7.2 Project vessels and helicopters

The drilling and completion, subsea installation and commissioning phases will be supported by project vessels including barges, tugs, survey vessels, supply vessels and installation vessels.

During the operations phase, vessel presence in the State Proposal Area will primarily be limited to IMR activities and environmental monitoring purposes.

Personnel transfer to offshore facilities from Broome will be either via helicopter or vessel. If helicopters are used, it is anticipated that up to five personnel transfers a week per FPSO facility will be required during normal operations. Helicopters will not enter the State Proposal Ara under normal operations, however they will traverse State Waters near the mainland.

Fast crew transfer vessels (FCTVs) may be used for crew transfer. These crew transfer vessels are capable of travelling at 50 – 55 knots. It is anticipated one transfer per day will occur during normal operations, with additional transfers during shut downs and major maintenance. FCTVs will not enter the State Proposal Area around Scott Reef under normal operations. They will traverse coastal State waters near the logistical base.

Vessel requirements during the decommissioning phase are unknown at this stage as decommissioning plans have not been finalised. However, it can be expected decommissioning may use similar vessels to those engaged for installation activities.

5.4 Local and Regional Context

The local context for the proposed Browse to NWS Project is provided in **Chapter 5** of the draft EIS/ERD. Specifically, values relating to the State Proposal Area include the following:

- the Scott Reef Nature Reserve (**Section 5.3.3.3** of the draft EIS/ERD)
- the Seringapatam Reef and Commonwealth waters in the Scott Reef Complex and the Continental Slope Demersal Fish Communities KEFs, which overlap the State Proposal Area (**Section 5.3.3.1** of the draft EIS/ERD)

- Biological Important Areas (BIAs) (green turtle, hawksbill turtle, little tern, pygmy blue whale; Section 5.3.2.2 of the draft EIS/ERD) and habitat critical to the survival of a species (green turtle; Section 5.3.2.3)
- Environment Protection and Biodiversity Conservation Act 1999 (EPBC Act) Listed species (Section 5.3.2.1 and Section 5.3.2.4 of the draft EIS/ERD)
- socio-economic values including commercial, traditional and recreational fishers (Sections 5.4.2.2 and Section 5.4.2.3 of the draft EIS/ERD) and scientific research (Section 5.4.2.7 of the draft EIS/ERD).

Regional context and values relevant to the proposed Browse to NWS Project, such as Commonwealth Managed Fisheries and State and Australian Marine Parks (AMPs), are also detailed in Chapter 5 of the draft EIS/ERD.

6. STAKEHOLDER ENGAGEMENT

6.1 Key Stakeholders

Refer to Table 4-1 in Section 4.3 of the draft EIS/ERD for a list of the identified stakeholders in relation to the proposed Browse to NWS Project.

6.2 Stakeholder Engagement Process

Refer to Chapter 4 of the draft EIS/ERD for an overview of the stakeholder engagement process, including historical stakeholder engagement relating to the development of the Browse resource, stakeholder engagement undertaken specific to the proposed Browse to NWS Project and planned ongoing stakeholder engagement.

6.3 Stakeholder Consultation

Refer to Table 4-2 in Section 4.3 of the draft EIS/ERD for an outline of engagements undertaken in relation to the proposed Browse to NWS Project following the referral of the proposed Browse to NWS Project in October 2018.

7. IDENTIFYING IMPACTS AND RISKS

The environmental impact and risk assessment process undertaken in relation to the proposed Browse to NWS Project is described in Section 6.2.3 of the draft EIS/ERD. This process included the identification of impacts and risks as well as associated receptor groups, as presented in Table 6-2, which shows the project wide aspect-receptor relationships. To inform the assessment in relation to the EPA's environmental objectives, the aspect-receptor relationships specific to activities occurring within the State jurisdiction have been identified and are shown in Table 7-1. Within Table 7-1, aspects that present a potential impact from a planned activity are identified with an 'I'. Where the aspect presents a risk from an unplanned event or incident they are identified with an 'R". Where both an impact and a risk apply, this is identified by 'I/R'. As application of the EPA Factors inherently result in overlap between aspects some repetition is necessary. This has been minimised wherever possible by subdividing aspects between Factors and cross referencing to the draft EIS/ERD.

Table 7-1 Aspect-Receptor Relationship of the State Proposal

8. ENVIRONMENTAL PRINCIPLES AND FACTORS

8.1 Principles

Consideration of the Proposal in relation to the Environmental Protection Principles and objects of the EP Act are presented in Table 8-1.

Table 8-1: Consideration of Environmental Protection Principles

Principle	Consideration
The precautionary principle Where there are threats of serious or irreversible damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation. In application of this precautionary principle, decisions should be guided by: a. careful evaluation to avoid, where practicable, serious or irreversible damage to the environment; and b. an assessment of the risk-weighted consequences of various options.	Credible and defensible science has been at the core of the environmental assessment of the proposed Browse to NWS Project. This science is underpinned by over 25 years of studies and research at Scott Reef in partnership with the Australian Institute of Marine Science (AIMS). This scientific knowledge has been incorporated into the selection of the concept for the proposed Browse to NWS Project, as well as into design during the concept definition phase. Scientific knowledge will continue to be a key input into the detailed engineering phase and the implementation of the environmental mitigation, management and monitoring programs. Studies completed were determined to be adequate for the purposes of impact assessment and management planning purposes based on the lack of significantly altered regional cumulative impacts since collection, ability to extrapolate population trends using existing literature, and conservative interpretation of available data where applied. The existing baseline data will be updated by targeted monitoring programs to verify impact predictions and inform adaptive management approaches at relevant times throughout the project life cycle. Woodside has committed to the continuation of the Scott Reef longterm monitoring program to monitor the functionality and status of the reef system throughout the full lifecycle of the proposed Browse to NWS Project. As described in the Chapter 6 of the draft EIS/ERD, serious or irreversible damage to the environment associated with the Proposal is not predicted to occur. The ongoing integrity of all ecological and socio-economic values of the Scott Reef system is central to the considerations of the State Proposal Area. Serious or irreversible damage to the environmental value of the Scott Reef system will be avoided by locating the FPSO facilities, BTL and interfield spur line well away from Scott Reef (outside of State waters) and by locating the subsea infrastructure within the State Proposal Area in deep waters, well away from Scott Reef shallow water habitat. No activities related to petroleum recovery are planned to occur on Scott Reef (<75 m water depth). The assessment presented here and in the draft EIS/ERD was conducted based on environmental objectives defined by Woodside, in accordance with relevant legislative requirements, corporate standards, benchmarking and industry best practice. Where relevant, additional management and mitigation measures have been identified for implementation to reduce the level of risk associated with aspects of the Proposal. These proposed management and mitigation measures have been developed using Woodside's adaptive management framework (Eliminate/Substitute/Prevent/Reduce/Mitigate). The adaptive management approach encompasses a range of measures to address uncertainties over environmental impacts and ensure that the EPA's environmental objectives are met. As such, it is considered this environmental protection principle has been and will continue to be met.

Principle	Consideration
The principle of intergenerational equity The present generation should ensure that the health, diversity, and productivity of the environment is maintained and enhanced for the benefit of future generations.	As described above, serious or irreversible damage to the environment is not predicted to occur as a result of the Proposal. In addition, environmental risks have been reduced to an acceptable level with the likelihood of impacts occurring as a result of unplanned events or incidents considered highly unlikely to remote. It is considered maintenance of the health, diversity and productivity of the environment will not be adversely impacted by the Proposal and access to the Scott Reef natural environment for future generations will be maintained. As such, it is considered this environmental protection principle has been and will continue to be met.
Principles relating to improved valuation, pricing, and incentive mechanisms 1. Environmental factors should be included in the valuation of assets and services. 2. The polluter pays principles – those who generate pollution and waste should bear the cost of containment, avoidance, and abatement. 3. The users of goods and services should pay prices based on the full lifecycle costs of providing goods and services, including the use of natural resources and assets and the ultimate disposal of any waste. 4. Environmental goals, having been established, should be pursued in the most cost-effective way, by establishing incentive structures, including market mechanisms, which enable those best placed to maximise benefits and/or minimise costs to develop their own solutions and responses to environmental problems.	In line with Woodside's HSEQ Policy, Woodside has drawn from its operating experience in Australian offshore environments and its knowledge of the existing environment of the State Proposal Area to identify a range of design features and management measures to prevent or mitigate impacts to the environment. The selection of these measures for implementation included the following key aspects: + In line with its corporate policies and procedures, Woodside will use valuation, pricing and incentive mechanisms during procurements associated with the proposed Browse to NWS Project with the aim of balancing economic and HSE outcomes. + Net environmental benefits will be compared against a range of alternative measures. + Costs involved with the implementation of management measures at various stages of the lifecycle of the Proposal will and have been compared. + Key environmental objectives will be established, to maximise environmental benefits in a cost-effective way. As such, it is considered that this environmental protection principle has been and will continue to be met.

Principle	Consideration
The principle of the conservation of biological diversity and ecological integrity Conservation of biological diversity and ecological integrity should be a fundamental consideration.	As part of the development of the State ERD, management and mitigation measures have been identified to reduce the level of risk for each of the environmental aspects associated with the Proposal. These proposed measures have been developed using Woodside's adaptive management framework (Eliminate/Substitute/Prevent/Reduce/Mitigate), with the overall objective to conduct activities associated with the proposed Browse to NWS Project in a manner which does not affect Ecological Sustainable Development outcomes. This includes the principles of the EP Act, including the principle of 'biological diversity and ecological integrity'. Woodside has developed a range of design features, as well as management and mitigation measures to avoid impacts to Scott Reef (refer to **Section 8**). These have been developed in consideration of the environment of Scott Reef. In addition, Woodside has committed to the continuation of the Scott Reef long-term monitoring program to monitor the functionality and status of the reef system, throughout the full lifecycle of the proposed Browse to NWS Project. As such, it is considered this environmental protection principle has been and will continue to be met.
The principle of waste minimisation All reasonable and practicable measures should be taken to minimise the generation of waste and its discharge into the environment.	Woodside is committed to managing its activities to reduce the adverse effects on the environment while balancing economic and social needs of sustainable development. A key principle of Woodside's HSEQ Policy is to use energy, water and other resources efficiently and reduce greenhouse gas (GHG) emissions and waste. This principle is reflected in the various design features and waste management measures to be implemented by Woodside. In the development of its management approach for the Proposal, Woodside has specifically focused on reduction at source and efficiency maximisation for emissions and discharges to the environment, as follows: + There will be no routine discharge of non-hazardous solid waste at sea. + Chemicals that may be operationally released or discharged to the marine environment will be subject to Woodside's chemical selection and assessment process and approved prior to use. + The flowline length and subsea infrastructure installation schedule will be optimised to reduce the volume of hydrotest fluid discharged. + There will be no discharge of untreated sewage within three nautical miles (nm) of Scott Reef. + The number of wells has been, and will continue to be, optimised to meet hydrocarbon recovery objectives and operational requirements and thereby reduce unnecessary use of drilling fluids and generation of drill cuttings. Solids control equipment will be available on board the MODU to reduce the amount of residual drill fluids on cuttings prior to discharge. Drill cuttings will be tested to confirm that the average oil on cuttings for the entire well (sections using non water based fluids (NWBFs)) will not exceed 6.9% by wet weight. + Dry commissioning is being pursued for the BTL + A hybrid subsea control system has been designed to return fluids to the FPSO for reuse during normal operations. Woodside has set performance criteria to be monitored as part of the Proposal to ensure the effective management of waste. As such, it is considered this environmental protection principle has been, and will continue to be, met.

8.2 Key Environmental Factor – Marine Environmental Quality

8.2.1 EPA Objective

The EPA objective for marine environmental quality is *"to maintain the quality of water, sediment and biota so that environmental values are protected"* (EPA, 2016a).

The EPA Environmental Factor Guideline for Marine Environmental Quality defines the term 'environmental quality' as "the level of contaminants in water, sediments or biota or to changes in the physical or chemical properties of waters and sediments relative to a natural state. It does not include noise pollution, which is dealt with separately under the marine fauna factor." (EPA, 2016a).

8.2.2 Policy and Guidance

The following policy and guidance have been considered in relation to the EPA environmental factor - marine environmental quality.

+ EPA Policy and Guidance
+ Statement of Environmental Principles, Factors and Objectives (EPA, 2016b)
+ Environmental Factor Guideline – Marine Environmental Quality (EPA, 2016a)
+ Technical Guidance – Protecting the Quality of Western Australia's Marine Environment (EPA, 2016c).

Other Policy and Guidance

+ Australian and New Zealand Guidelines for Fresh and Marine Water Quality (ANZG, 2018).

8.2.3 Receiving Environment

The characteristics of the marine environment of the Browse Development Area are described in detail in Chapter 5 of the draft EIS/ERD.

Water quality and seabed sediment quality in the deep waters (below the 75 m bathymetric contour) within the State Proposal Area are well aligned with that of the broader Browse Development Area and typical of a pristine tropical offshore environment reflective of the anthropogenically undisturbed waters of the region.

The findings of three surveys have been used to characterise water quality in the State Proposal Area (Brinkman et al., 2009; Gardline Marine Services Pty Ltd, 2009a; URS Australia Pty Ltd, 2007) as described in Section 5.2.9 of the draft EIS/ERD.

These studies have also been used to characterise the deepwater seabed sediments within the Browse Development Area, as described in Section 5.2.10 of the draft EIS/ERD. These surveys found no evidence of hydrocarbons within the sediment in the Browse Development Area, generally low levels of metals (majority below guideline levels), and nutrient levels well within the normal baseline values expected for carbonate-dominated sediments in remote tropical settings.

Biota associated with the deepwater seabed habitats within the Browse Development Area are described in Section 5.3.1 (ecological communities) and Section 5.3.2 (fauna) of the draft EIS/ERD. Planktonic communities within the open waters of the State Proposal Area are expected to be consistent with the remainder of the Browse Development Area. A description of the shallow water benthic habitats associated with the Scott Reef system (above the 75 m bathymetric contour) is provided in Section 8.3.3. A description of the marine fauna found in the State Proposal Area is provide in Section 8.4.3. As described in Section 6 of the draft EIS/ERD, for the purposed of this State ERD, Scott Reef is considered as the area above the 75 m bathymetric contour within the 3 nm State waters boundary.

State marine parks and nature reserves are described in Section 5.3.3.3 of the draft EIS/ERD. State managed fisheries are described in Section 5.4.2.2 of the draft EIS/ERD.

8.2.4 Potential Impacts

8.2.4.1 Summary of identified impacts and risks

Table 8-2 summarises the sources of potential impact to marine environmental quality in the State Proposal Area from the Proposal. Table 8-2 is followed by a detailed description of the potential direct, indirect and cumulative impacts. An assessment of the significance of these impacts on marine environmental quality and a conclusion on the acceptability of the impacts in relation to the EPA environmental objective is presented in Section 8.2.5. It should be noted that a discussion of the impacts from the predicted activities on marine fauna and benthic 'biota' as a component of marine environmental quality is presented in Sections 8.2 and Section 8.4.

Table 8-2 Sources of Potential Impact to Marine Environmental Quality from the Proposal

Aspect	Proposal Phase[1]					Source (in State jurisdiction)
	Dr	I	C	O	De	
Planned (routine and non-routine activities)						
Physical presence: light emissions	✓	✓	✓	✓	✓	Project vessels, installation vessels and MODU operating in the State Proposal Area Intermittent flaring from the MODU
Physical presence: seabed disturbance and disturbance to other users	✓	✓		✓	✓	Development of the production wells Installation of subsea infrastructure Wet storage of infrastructure prior to installation MODU anchors IMR activities
Marine discharges: sewage and sullage	✓	✓	✓	✓	✓	Project vessels, installation vessels and MODU operating in the State Proposal Area
Marine discharges: treated utility water, chemical and deck drainage	✓	✓	✓	✓	✓	Project vessels, installation vessels and MODU operating in the State Proposal Area
Marine discharges: produced water	✓					MODU during well unloading activities
Marine discharges: cooling water	✓	✓	✓	✓	✓	Project vessels, installation vessels and MODU operating in the State Proposal Area
Marine discharges: drilling or completions discharges	✓					MODU during drilling activities
Marine discharges: subsea control fluids	✓	✓		✓	✓	Subsea infrastructure BOP during drilling Remotely Operated Vessels (ROVs)
Marine discharges: hydrotest fluid	✓	✓	✓	✓		Temporary production system on MODU Integrity testing of subsea infrastructure
Unplanned events and incidents						
Marine discharges: hazardous and non-hazardous inorganic waste	✓	✓	✓	✓	✓	Project vessels, installation vessels and MODU operating in the State Proposal Area
Unplanned hydrocarbon releases	✓	✓	✓	✓	✓	Project vessels, installation vessels and MODU operating in the State Proposal Area Subsea infrastructure

[1] *Dr = Drilling; I = Installation; C = Commissioning; O = Operation; De = Decommissioning*

8.2.4.2 Physical presence: seabed disturbance

As described in **Section 6.3.1.6** of the draft EIS/ERD, seabed disturbance as a result of the installation of subsea infrastructure (including pre-lay activities, placement and post lay rectification of infrastructure), wet storage (which involves temporarily placing equipment on the seabed), anchoring of the MODU and IMR activities within the State Proposal Area is expected to be approximately 4.15 km^2 in area of which 0.31 km^2 will constitute direct disturbance resulting in permanent impact. The 3.84 km^2 balance is the result of indirect disturbance and is considered reversible. Seabed disturbance is likely to result in temporary and localised displacement of naturally-occurring sediments for the duration of the activity (ranging in the order of minutes to a few hours) and limited to the immediate disturbance area. This is likely to result in increases in turbidity levels at the seabed that will quickly disperse in the oceanic marine environment due to prevailing hydrodynamic conditions. As such, any reduction in water quality will be temporary (ranging in the order of minutes to a few hours) and will be limited to the water column immediately surrounding the disturbance area. The sediments that may be displaced are naturally occurring and, based on baseline surveys as described in **Section 5.2.10** of the draft EIS/ERD, do not contain any contaminants of concern. Due to the temporary and localised nature of changes in water quality, impacts to plankton are negligible.

Further, the small volumes of sediment mobilised, the water depth at which the seabed disturbance will occur, and the dynamic nature of the marine environment means that it is highly unlikely that any mobilised sediments will deposit on Scott Reef shallow water benthic habitats (<75 m water depth).

Given this, turbidity and associated sedimentation generated by seabed disturbances is not expected to result in any lasting change to the physical or chemical properties of water or sediments; or result in any lasting adverse impact to biota. As such minor impacts are expected to deep-water benthic communities and habitats (>75m water depth) are predicted. No impacts to Scott Reef shallow water benthic communities and habitats (<75 m water depth) located well away from the closest proposed location of the subsea infrastructure are predicted.

8.2.4.3 Physical presence: light

Potential impacts to plankton from light emissions are described in **Section 6.3.3** of the draft EIS/ERD.

Zooplankton often display diurnal vertical movements (Leach and Johnsen, 2003) within the ocean, migrating to surface waters at night to feed. Artificial light has, therefore, the potential to reduce the amplitude of their migration if lighting levels are sufficiently high at night (Moore et al., 2000). Artificial light emissions can influence the migration of zooplankton from deepwater to the surface, thereby affecting the food supply of nocturnal plankton-feeders. Alternatively, as most studies have demonstrated, the illumination of marine waters at night has the effect of increasing feeding opportunities for predators due to better visualisation of prey rather than resulting in potential plankton density reduction, however, these effects are expected to be highly localised and given the high turnover rate of plankton populations (ITOF, 2011) in open oceanic water there will be no lasting impact.

It is likely that plankton in the immediate vicinity of the FPSO facilities, MODU and project vessels that are within the light spill area (within hundreds of metres) will be impacted by light, based on the light emissions modelling. Given the highly localised effects of light emissions from the FPSO facilities, MODU and vessels associated with the proposed Browse to NWS Project, the proportion of the plankton population affected and the high turnover and recovery of plankton populations, no discernible impact on plankton communities at a population level is expected.

8.2.4.4 Marine discharges: sewage and sullage

A detailed description of the planned discharge of sewage and sullage and an assessment of the potential impacts and risks associated with the discharge are provided in **Section 6.3.9** of the draft EIS/ERD.

There are no planned discharges of untreated sewage or sullage within the State Proposal Area; however, discharges of treated sewage and sullage from project vessels, installation vessels and the MODU within the State Proposal Area will occur. These discharges will be primarily related to drilling activities and installation of the subsea infrastructure, with no permanent vessel presence in the State Proposal Area during operations. Under normal operating conditions, drilling and vessel activity (and associated marine discharges) will be limited to the deep waters in close proximity to the location of the proposed development wells and subsea infrastructure. Drilling activities are expected to take 2-3 months per well, with up to 24 wells in the State Proposal Area. It must be noted that all 24 wells will not be drilled in a continuous sequence. Approximately 3 wells will be installed at RFSU at the TRA drill centre, then remaining wells will in installed over subsequent years.

A review of current petroleum activities shows that vessels and MODUs typically generate around 5–15 m^3 of waste water (consisting of sewage and sullage) per day (NERA, 2017). Using a rate of 0.375 m^3/person/day as a guide (NERA, 2017), installation vessels may discharge approximately 22.5 m^3/day, based on 60 persons aboard.

The discharge of treated sewage and sullage has the potential to result in the temporary (minutes to hours) and localised (tens of metres) reduction in water quality via eutrophication as a result of increased nutrient levels (e.g. ammonia, nitrite, nitrate and orthophosphate). This has the potential to cause adverse changes to the ecosystem, such as increased growth of primary producers (e.g. phytoplankton) which can deplete oxygen in the water column and result in changes in biological processes.

Sewage and sullage may also include some particulate matter which can cause an increase in the turbidity of the receiving waters close to the point of discharge. Discharges will disperse and dilute rapidly, with concentrations of wastes significantly dropping with distance from the discharge point. Several studies have quantified the high levels of dilution, including Loehr et al. (2006). A study by the US EPA (2002) found that discharge plumes behind cruise ships moving at between 9.1 and 17.4 knots are diluted by a factor of between 200,000:1 and 640,000:1. The discharges and level of effluent dilution in the studies did not present significant localised toxicity impacts to marine biota from any changes in water quality.

As described in **Section 6.3.9** of the draft EIS/ERD, monitoring of sewage and sullage discharge during the drilling campaign for the Torosa-6 well in 2008 determined discharges were rapidly diluted in the upper (less than 10 m) water layer to 1% of their original concentration within 50 m, with no elevations above background in nutrients or metals recorded at any sampling station (ERM and SKM, 2008). As such, changes to the physical and chemical properties of the marine water will be temporary and highly localised. No change to the physical or chemical properties of sediments are expected due to the depth of the water where treated sewage and sullage would be discharged.

Although organic materials from the discharges will likely exert biological oxygen demand on the receiving waters, this is unlikely to reach levels below background ambient dissolved oxygen concentrations. Similarly, while the nutrient inputs from discharged effluent will rapidly be taken up by phytoplankton, pronounced increases in productivity as evidenced by increased chlorophyll a concentration are not expected. This is largely due to the assimilative capacity of the open ocean, with any potential additive nutrients not expected to accumulate in the vicinity of the discharge location. As such no lasting impacts to planktonic communities are expected.

Given the relatively small volume of treated sewage and sullage to be discharged, the distance from the discharge to Scott Reef and the expected rapid dilution of the discharge, the temporary and highly localised changes to water quality are not expected to have any impacts to biota or the environmental values of the Scott Reef system.

Though unlikely, discharges of sewage and sullage at levels significantly above the discharge specifications may result from human error or equipment failure. This would potentially result in a larger area being impacted (a temporary larger mixing zone), although the plume would still be expected to rapidly disperse. The subsequent temporary (i.e. limited to the duration of the unplanned discharge) and localised reduction in water quality would be unlikely to lead to subsequent impacts to deepwater receptors due to the depth of water; or to the Scott Reef system due to the distance from where the discharges would occur.

8.2.4.5 Marine discharges: treated utility water, chemical and deck drainage

A detailed description of the planned discharge of treated utility water, chemical and deck drainage and an assessment of the potential impacts and risks associated with the discharges is provided in **Section 6.3.10** of the draft EIS/ERD.

Within the State Proposal Area, treated utility water, chemical and deck drainage will be limited to deck drainage, treated bilge water and desalination brine from project vessels, installation vessels and the MODU. As described in **Section 6.3.10** of the draft EIS/ERD, potentially contaminated deck drainage discharges would occur from the MODU during periods of heavy rain, with potentially contaminated drainage routed to slops tanks for treatment prior to discharge. Bilge water from within machinery spaces will be captured separately in a bilge tank for treatment.

As described in **Section 6.3.10** of the draft EIS/ERD, an oil-in-water separator will be available onboard the MODU and vessels (as applicable to vessel class), which will be maintained and operated so that bilge water is treated to reduce hydrocarbon concentrations below 15 ppm in accordance with MARPOL 73/78 Annex. Under normal operating conditions, drilling and vessel activity (and associated marine discharges) will be limited to the deep waters in proximity to the location of the proposed development wells and subsea infrastructure.

Considering the composition of the drain discharges (i.e. small quantities of hydrocarbons and detergents) and assimilative capacity of the receiving environment, it is expected that drain discharges will rapidly dilute within the surrounding waters. As such, these discharges will result in temporary (lasting a few minutes) change to water quality in the immediate vicinity of the discharge. Given the water depth (>300 m) and distance to Scott Reef from where these discharges would occur, this change to water quality is not expected to have any impacts to sediment, biota or the environmental values of the Scott Reef system.

Desalination brine discharge is expected to be 20 to 50% more saline than the intake seawater (depending on the desalination process used) and therefore only a small number of dilutions will be required to achieve ambient salinity levels. Studies undertaken by the US EPA (Frick et al., 2001) determined that brine discharges from the surface dilute 40–fold approximately 4 m from the source. This modelling can be used as an indicator for predicting horizontal attenuation and diffusion of brine discharges. Given the proposed discharge volumes from the FPSO facilities (21.5 m^3/hr), which is the largest source of such discharges, dilution to ambient levels is likely to be achieved within a very short distance from the discharge point (<100 m). Therefore, owing to the likely high number of dilutions achieved following discharge from the proposed sources (i.e. FPSO, vessels and MODU), elevated salinity levels (above ambient) will be highly localised at the discharge point and unlikely to have a perceptible effect on ambient salinity concentrations in the water column.

Though unlikely, unplanned discharges resulting from human error or equipment failure on project vessels or the MODU may occur. This would potentially result in a larger area being impacted (a temporary larger mixing zone), although the plume would still be expected to rapidly disperse. The subsequent temporary (i.e. limited to the duration of the unplanned discharge) and localised reduction in water quality would be unlikely to lead to subsequent impacts to deepwater receptors due to the depth of water; or to Scott Reef system due to the distance from where the discharges would occur.

8.2.4.6 Marine discharges: produced water

A detailed description of the planned discharge of produced water (PW) and an assessment of the potential impacts and risks associated with the discharge of PW is provided in Section 6.3.12 of the draft EIS/ERD.

Low levels of PW may be discharged from the MODU at the well locations, including within deep water areas of the State Proposal Area during well unloading. This PW would be condensed water generated in the hydrocarbon gas stream during well unloading and would be discharged as part of the discharge of well clean up fluids, which would include drilling fluids (addressed below). The PW component of the discharge will constitute a very small proportion of the discharge stream, with the discharge dominated by suspension fluids and associated PW generally limited to small volumes of condensed water. Well unloading is anticipated to take 1-2 days per well (i.e. the amount of time that the well is flowing). The PW component of the discharge may contain inorganic salts from geological formations, dissolved organic compounds, dissolved gases (including H_2S and CO_2), dissolved and dispersed hydrocarbons, metals and low levels of Naturally Occurring Radioactive Material (NORMs).

Given the PW component is a fraction of the overall discharge during well unloading, this discharge is addressed below under drill cuttings and fluids.

8.2.4.7 Marine discharges: cooling water

A detailed description of the planned discharge of cooling water and an assessment of the potential impacts and risks associated with the discharge is provided in Section 6.3.13 of the draft EIS/ERD.

Cooling water discharge from project vessels and the MODU at the well locations may impact marine environmental quality due to thermal impacts (increased water temperature) and toxicity impacts relating to the residual chlorine concentration within the cooling water discharge.

Relatively low levels of cooling water will be discharged from project vessels and the MODU (approximately 50 m^3/day depending on vessel size). Under normal operating conditions, drilling and vessel activity (and associated marine discharges) will be limited to the deep waters near the location of the proposed development wells and subsea infrastructure.

To put this discharge volume in context, the FPSO facilities are expected to discharge up to approximately 720,000 m^3/day (discharge to Commonwealth waters). Modelling undertaken of the FPSO facilities cooling water discharge indicated a rapid dilution would be expected (Section 6.3.13 of the draft EIS/ERD). Given the markedly smaller discharge volumes from the vessels and MODU, these small volumes are expected to rapidly disperse and dilute (within tens of metres) with impacts expected to be a highly localised change in water quality. This reduction in water quality would be primarily limited to the construction phase, with vessel activities in the State Proposal Area during operations primarily limited to intermittent IMR activities. Due to the distance of proposed cooling water discharge to Scott Reef, the reduction in water quality is not expected to have any impacts to sediment, biota or the environmental values of the Scott Reef system.

8.2.4.8 Marine discharges: drilling or completions discharges

A detailed description of the planned discharge associated with the drilling activities and an assessment of the potential impacts and risks associated with the discharge are provided in Section 6.3.15 of the draft EIS/ERD. The impact assessment in the draft EIS/ERD focuses largely on activities in the State Proposal area however they are repeated here in order to provide a standalone assessment of impacts within State jurisdiction.

Development drilling activities within the State Proposal Area associated with the proposed Browse to NWS Project involve the drilling and completion of up to 24 wells. Drilling of production wells will generate drill cuttings, require cementing of the casing, and require the use of a range of fluids, that may be discharged to the marine environment, typically at the seabed and at or near the sea surface depending on the hole section.

During the life of the proposed Browse to NWS Project, well components will require maintenance, repair or replacement. This will require well intervention activities which generally occur within the wellbore and may include but not limited to well logging activities (slickline, wireline, coil tubing), well testing and flowback; and well workovers. Relevant discharge types generated from these activities may include subsea control fluid (control of subsea tree) (refer to Section 6.3.16 of the draft EIS/ERD), completions fluids and well annular fluids.

In addition, well abandonment activities can result in discharges to the marine environment including but not limited to installation and pressure testing of the blow out preventer (BOP), cutting/perforation of casing or production tubing; and installation of permanent reservoir and surface barrier (cementing). Relevant discharge types generated from these activities may include subsea control fluids (refer to Section 6.3.16 of the draft EIS/ERD), well annular fluids and cement.

Drilling and completion activities required for the proposed Browse to NWS Project are expected to be broadly similar to that of the previous development concepts (Section 2.7.1 of the draft EIS/ERD).

Drill cuttings

Drilling generates drill cuttings due to the breakup of solid material from within the borehole. The resultant drill cuttings are basically rock particles of various shapes, with sizes typically ranging from very fine to very coarse. Cuttings generated during drilling of the top-hole sections are typically discharged to the seabed at the well site.

Once the top-hole sections are complete, installation of the riser and BOP provides a conduit back to the MODU, forming a closed circulating system. The bottom hole sections will be drilled with a marine riser in place that enables cuttings and drilling fluids to be circulated back to the MODU, where the cuttings are separated from the drilling fluids by the solids control equipment (SCE). The SCE comprises equipment such as shale shakers, cuttings dryer(s) and centrifuges. The SCE uses shale shakers to remove coarse cuttings from the drilling fluid. The recovered fluids from the cuttings may then be directed to centrifuges, which are used to remove fine solids (4.5 to 6 µm). The cuttings are usually discharged below the water line and the fluid is recirculated into the fluid system.

The drilling fluid retained on cuttings is determined by the SCE and typically, treated water based fluid (WBF) cuttings may retain 5 to 25% of the drilling fluid after passage through SCE (Neff, 2005) and treated cuttings when drilling with non water based fluid (NWBF) may retain 5 to 15% of the drilling fluid (Neff et al., 2000). The cuttings with retained NWBF will also pass through a cuttings dryer and associated SCE, to reduce the average oil on cuttings to 6.9% wt/wt or less on wet cuttings, prior to discharge.

The fate and dispersion of the cuttings once discharged into the marine environment is determined by particle size and the density of the unrecoverable fluids. The larger cuttings particles will drop out of suspension and deposit in close proximity to the well site (tens of metres) with potential for localised spreading downstream. In contrast, the finer particles will remain in suspension and be transported away from the well site, rapidly diluting and eventually depositing over a widespread area (hundreds of metres) downstream of the well site.

Drill cuttings and unrecoverable fluids are discharged at the seabed at the well site for the top-hole sections drilled riser-less (no closed loop with the MODU). This results in a localised area of sediment deposition (known as a cuttings pile) in close proximity to the well site. The spread of cuttings and associated water based fluids is expected to be up to 50-200 m downstream from the discharge location based on a review of seven studies summarised by International Association of Oil and Gas Producers (IOGP, 2016). Drill cuttings and retained NWBF (<6.9% OOC) released at or below the surface after treatment on the MODU for the bottom-hole well sections are generally dispersed and settle within a seabed area confined to a maximum of 500 m distance of the discharge point (IOGP, 2016).

Drilling fluids

Drilling fluids (also termed drilling muds) serve many purposes including maintaining borehole stability and hydrostatic pressure, reducing friction and cleaning/cooling of the drill bit, in addition to acting as a medium to carry cuttings from the well bore and return them to the surface at seabed or on the MODU. Drilling fluids are either mixed on the MODU or received pre-mixed, then stored and maintained in a series of mud pits aboard the MODU or a suitable vessel. There are two main types of drilling fluids, including water based fluids (WBF) and non-water based fluids (NWBF).

Water based drilling fluids

The proposed Browse to NWS Project will use WBF as the preferred option. WBF consists mainly of seawater with the addition of chemical and mineral additives to aid in its function. Drilling additives typically used may include chlorides (e.g. sodium, potassium), bentonite (clay), cellulose polymers, guar gum, barite or calcium carbonate. These additives are either completely inert in the marine environment, naturally occurring benign materials, or readily biodegradable organic polymers with a very fast rate of biodegradation in the marine environment.

WBF will be discharged to the marine environment at the location of the well being drilled under the following scenarios:

- at the seabed when drilling the top-hole (riser less) sections
- below sea surface as fluid remaining on drill cuttings, after passing through SCE (bottom-hole sections, drilled with riser in place)
- from the mud pits via a discharge pipe below the sea surface, If WBF cannot be re-used due to bacterial deterioration or does not meet required drilling fluid properties, it may be discharged to the marine environment using seawater flushing. WBF may not be able to be reused between drilling sections due to the drilling sequence, technical requirements of the fluid (i.e. no tolerance for deterioration of fluid during storage) and maintenance of productivity/injectivity. Unused or spent WBFs may be disposed from the MODU as a bulk discharge (defined as a discrete discharge of large quantities) at the end of each well section.

Additional products such as barite and bentonite may be discharged in bulk/single discharge at the end of the activity if they cannot be reused or taken back to shore. Use and discharge of all chemicals will be performed in line with Woodside's internal guidelines. Discharge may be in the form of dry bulk or as a slurry; however, discharges will not be contaminated with hydrocarbons. Planned bulk discharges at wells within the State Proposal Area will be managed as described in the **Management approach - Torosa wells in the State Proposal Area** section below.

Non water based drilling fluids

Non-water-based fluids (NWBF) refers to drill fluids that are hydrocarbon rather than water based fluid. NWBF may be used to manage well stability to safe levels based on the offset history, geohazards assessment and borehole stability studies. Like a WBF system, a range of standard solid and liquid additives may be added to alter specific fluid properties for each section of the well, dependent on the conditions encountered while drilling. NWBFs will be selected in accordance with Woodside's chemical selection and assessment process on the basis of lowest health, safety and environmental risks while meeting operational requirements.

During drilling operations, the NWBF (like WBF) are pumped by high pressure pumps down the drill string and out through the drill bit, returning via the annulus between the drill string and the casing of the well bore, and back to the MODU via the riser. Discharge scenarios are much the same as that described for WBF, however NWBF will not be used for top-hole section drilling (riserless); therefore, no direct seabed discharge of NWBF will occur.

The NWBF that cannot be re-used (i.e. do not meet required drilling fluid properties or are mixed in excess of required volumes) are recovered from the mud pits and returned to the shore base for onshore processing for recycling and/or disposal. The mud pits and associated equipment/ infrastructure are cleaned when NWBF is no longer required, with wash water discharged with mud pit washings, or returned to shore for disposal if discharge criteria cannot be achieved.

There are typically a number of mud pits (tanks) on the MODU that provide a capacity to mix, maintain and store fluids required for drilling activities. The mud pits form part of the drilling fluid circulating system. The mud pits, any supply vessel storage tanks carrying WBF or NWBF, and associated equipment/infrastructure are cleaned out during and at the end of drilling and completions operations. Mud pit wash residue is operationally discharged from the MODU with less than 1% oil contamination by volume. Where the mud pit residue exceeds 1% by volume, the residue will be retained and disposed onshore.

Drilling fluids toxicity

Components of the WBF system have a low toxicity. Bentonite and guar gum are listed as 'E' category fluids under the OCNS and is included on the Oslo Paris (OSPAR) Commission PLONOR (chemicals that 'pose little or no risk to the environment') list (OSPAR, 2019). They may, however, cause physical damage to benthic organisms by abrasion or clogging, or through changes in sediment texture that can inhibit the settlement of planktonic larvae, such as polychaete and mollusc early life stages (Swan et al., 1994). However, these impacts are not expected to be significant due to the rapid biodegradation and dispersion of WBFs (Terrens et al., 1998).

NWBF may contain a range of synthetic hydrocarbons, such as paraffins and olefins; however, such additives are designed to be low in toxicity and biodegradable, as well as not being readily bioavailable or likely to bioaccumulate amongst the deepwater benthic biota that live within the seabed (infauna) or on the seabed (epifauna). However, it is noted that microbial biodegradation can result in oxygen reduction within sediments. Nedwed et al. (2006) however, found that depth is an important factor for residual concentrations of NWBF once they reach the seabed, suggesting that loss of base fluid during settling acted to significantly reduce chemical effects from discharges. It is also noted that NWBF cuttings tend to clump and settle to the seabed rapidly adding to the cuttings pile in proximity to the well site. The Nedwed et al. (2006) study concluded that NWBF discharged in deep water caused very limited environmental impacts (from analysis of differences in benthic fauna between pre- and post-drilling samples).

Cement

Once each of the top-hole sections are drilled, casing is installed in the wellbore and secured in place by pumping cement into the annular space and may involve a discharge of excess cement at the seabed (~80 m^3/well). Wherever possible, the cement line flush volumes are included in the planned cement jobs. When a job is completed, the cement unit is cleaned, and the residual cement discharged overboard. The discharge volumes of residual cement products are approximately 1 m^3.

At the commencement of the drilling campaign there may be a requirement to run a cement unit test to test the functionality of the cement unit and the cement bulk delivery system prior to performing an actual cement job. This test would result in a small volume of approximately 10 m^3 of cement slurry being discharged at surface to sea. The slurry is usually a mix of cement and water however may sometimes contain stabilisers or chemical additives. Excess cement (dry bulk) after well operations are completed, will be held onboard and used for subsequent wells, provided to the next operator at the end of the program, or discharged to the marine environment. Planned bulk discharges at wells within the State Proposal Area will be managed as described in the **Management approach - Torosa wells in the State Proposal Area** section below.

Completion fluids

Completion fluids are usually brines (i.e. a mixture of seawater or formation water) with additives that can include chlorides (often sodium, potassium or calcium), bromides, hydrate inhibitor (MEG), biocide and/or oxygen scavenger. They are designed to have the proper density and flow characteristics to be compatible with the reservoir formation. Completion fluids may also include solids-free fluid, gravel pack carrier fluid and loss circulation material. Completion fluids are used during wellbore clean-up, while running completions, and may be returned to surface during well unload activities. Most of the gravel pack carrier fluid is bulk discharged.

Wellbore and casing clean-up are required at various stages of the operations to ensure the contents of the well are free of contaminants before the next stage of well construction. A chemical wellbore cleanout fluid train may be used to remove residual fluids (including NWBF, if used) from the wellbore. The wellbore cleanout fluid is usually brine (similar to completion fluid) that can include several chemicals, such as biocide and surfactant. During the wellbore clean-out process, fluids are circulated back to the MODU, and, if required, analysed before they are discharged overboard. Discharge volume would be ~400 m^3 (based on the designs of the proposed production wells).

A brine of adequate density to control formation pressure may also be used during well suspension or well abandonment.

Well unload

During well unloading activities, all completion and reservoir fluids will be flared or discharged to the environment. The base oil column, completion fluid, some drilling fluid remnants, hydrocarbons and produced/condensed water will be measured, handled, separated, treated for overboard discharge (non-hydrocarbon) and flared/burned (hydrocarbon) through the temporary production system on the MODU.

The well test water treatment package will be used to treat produced/reservoir water before discharge. Prior to discharging, the fluids are cycled through an oilbond filtration system and gauge tank. Water filtration is standard practice for well unloading operations.

Discharges will occur during well unloading to a MODU or suitable vessel. These discharges will constitute leftover drilling fluids, completion fluids and small amounts of produced water (PW; refer to **Section 8.2.4.6**) Well unloading is anticipated to take 1-2 days per well, and discharge of fluids during this time has been indicatively estimated at approximately 100 m^3 to 130 m^3 per well.

Well annular fluids

Annular fluids fall within the category of completion fluids and refer to the fluids that remain in the annular spaces between the casing and previous casing strings or formation. It may consist of weighted drilling fluid and cement-contaminated mud, seawater, barite, cement, polymer, and may include small amounts of hydrocarbon. For the proposed Browse to NWS Project, the reference case annular fluid is base oil with no additivities apart from a demulsifier.

If a well is underperforming, or surveillance indicates debris is contained within the well, the contents of the wellbore may be flowed to a MODU. This displaces the well fluids (i.e. suspension/completion fluids). These are discharged overboard, as potential gas content makes it too dangerous for personnel to filter or treat them.

WBF used during riserless drilling will be released to the marine environment when the well head is removed during abandonment. Upon wellhead removal, small volumes (~ 1 m^3) of fluid exchange between the annular spaces and the ocean may occur. The exchange will not be instantaneous as the annular spaces are small and the fluids are typically heavier than seawater, however, as the fluids are released it is expected that they will be rapidly diluted within metres of the release location.

Overview of drill cuttings and drilling fluids

An indicative well profile is shown in **Table 8-3**. During drilling of the top-hole well sections drill cuttings (~ 625 m^3) and drilling fluids (~ 1,095 m^3) based on a typical well profile are generated and will be released from the well directly onto the seabed. During drilling of the bottom-hole well sections, drill cuttings (~ 225 m^3) and drilling fluids (~ 1,020 m^3) based on a typical well profile are generated and may be discharged at or below the sea surface.

Table 8-3 Indicative cuttings volumes and fluid type for a typical Browse well

Indicative well section diameter	Indicative Drill Length (m)	Indicative Cuttings Volume (m^3)	Indicative Fluids Volume (m^3)	Indicative Fluid Type
42”	100	89 m^3	427	Seawater with bentonite sweeps
26”	440	151 m^3	1327	Seawater with bentonite sweeps
16”	2970	385 m^3	965	Weighted Gel (Bentonite) WBF
12 ¼	2799	213 m^3	925	WBF or NWBF
9 ⅞	243	12 m3^3	790	WBF or NWBF
Total per well	**6,552 m**	**850 m^3**	**4,435 m^3**	

Contingent drilling activities include well side-track and well respud. If either of these activities are required, they will result in additional volumes of drilling discharges equal to the re-drilled sections of the well. The impacts of these unlikely scenarios are broadly covered by the base case impact assessment considerations.

It should be noted that the detailed impact evaluation with modelling is based on the primary drilling discharges (cuttings and residual fluids) due to the nature, scale and duration of the discharge compared to other sources (e.g. completion fluids). These results have been used to support impact and risk assessment and in the determination of acceptability in the context of the receiving environment and relevant receptors.

Modelling
Modelling of surface discharge of drill cuttings was undertaken for the previous development concepts and is presented in **Section 6.3.15.3** of the draft EIS/ERD.

The modelling indicated that, at all three drill centre locations, the sea surface discharge of drill cuttings from bottom hole sections of wells resulted in incursions of sediment plumes and associated increased deposition at some parts of North and South Scott Reef including within the lagoons. As a result, Woodside has committed to manage drilling discharges (in particular bottom hole discharges) at drill centre locations in the State Proposal Area (i.e. TRA, TRD, TRE and TRF) in such a manner to avoid impacts to Scott Reef shallow water benthic communities and habitats (<75 m water depth). This management approach is further described in **Section 8.2.6**.

In contrast, the seabed discharge of drill cuttings from top-hole well sections may result in sediment plumes and associated deposition of sediment to the surrounding seabed and was confined to the deeper layers of the water column with no contact with deeper water or shallow water coral habitats at Scott Reef. As outlined in **Section 5.2.5.7**, while there is some evidence of localised intrusions of cooler water around the western and eastern entrances to the channel between North and South Scott Reef during spring tides, there is no evidence of persistent upwelling or downwelling currents around Scott Reef (Green et al., 2019) and therefore, no transport mechanisms to mobilise drill cuttings from deep waters to the shallower waters of the reef system. As such, given the location of the drill centres in deep water, which experience strong surface and subsurface currents, drill cuttings and fluid discharge disposal at seabed would be expected to settle rapidly. Therefore, any reduction in water quality such as elevated TSS is expected to occur in a localised area around the drill centre and will be temporary in nature.

To further inform the impact assessment, for the seabed discharge of drill cuttings generated from the top-hole sections of the wells, the modelling results indicated that at the:

- previously proposed TRE drill centre location (water depths of 360 m):
  - Sediment plume predominantly extended westward, driven by the stronger ebb tide, with some eastward extension during the flood tide (**Figure 6-34** of the draft EIS/ERD).
  - Cuttings sedimentation would be limited to the deep seabed and water layers of the channel, with no sedimentation on Scott Reef shallow water benthic communities and habitats (<75 m water depth) including in the lagoons of North and deeper water coral habitat of South Scott Reef.
  - Maximum net sediment deposition over the duration of the 12-month drilling program is estimated at approximately 46 cm at the previously proposed TRE drill centre location (**Figure 6-34** of the draft EIS/ERD).

- previously proposed TRD drill centre location (water depths of 400 m):
    - Sediment plume confined to the deepwater layers of the water column (Figure 6-41 of the draft EIS/ERD).
    - Modelling did not predict elevated suspended sediment concentrations or net sedimentation at Scott Reef Scott Reef shallow water benthic communities and habitats (<75 m water depth) including in the lagoons of North and deeper water coral habitat of South Scott Reef.
    - Net sediment deposition over the duration of the drilling program is approximately 35 cm at the previously proposed TRD drill centre location (**Figure 6-35** of the draft EIS/ERD).
- previously proposed TRA/TRB drill centre location (water depths of 460 m):
    - Sediment plume confined to the deep-water layers and was not expected to reach Scott Reef Scott Reef shallow water benthic communities and habitats (<75 m water depth) including in the lagoons of North and deeper water coral habitat of South Scott Reef (**Figure 6-36** of the draft EIS/ERD)).
    - Sedimentation was predicted to extend eastwards of Scott Reef, influenced by the north-west south-east tidally-induced currents.
    - Net sediment deposition at seabed over the duration of the drilling program is approximately 21 cm at the previously proposed TRA/TRB drill centre location **Figure 6-42** of the draft EIS/ESD).

Maximum suspended sediment concentrations in the water column in the vicinity of the release points (near the seabed) was predicted to reach 1250 mg/L at TRE, 1530 mg/L at TRD and 2500 mg/L at the previously proposed TRA/TRB drill centre location.

Management approach - Torosa wells in the State Proposal Area

Modelling indicated that the sea surface discharge of drill cuttings from the bottom-hole sections generated at the previously proposed TRE and TRD drill centre locations would potentially result in incursions of sediment plumes and associated increased sedimentation to portions of North and South Scott Reef including within the lagoons.

Given the potential sensitivities of Scott Reef shallow water benthic habitat (<75 m bathymetry) to sedimentation from drilling discharges, Woodside has committed to managing the drilling discharges (in particular, bottom-hole section discharges) at drill centre locations in the State Proposal Area (i.e. TRA, TRD, TRE and TRF) in such a manner to avoid potential impacts to Scott Reef shallow water benthic communities and habitats (<75 m water depth). This approach is as follows:

1. For each identified drill centre, drilling discharge modelling will be completed using final design data to assess the dispersion and fate of drill cuttings, residual drilling fluids on cuttings, as well as bulk discharge (collectively referred to as drilling or completions discharges). This information will be provided in the relevant Environment Plan.
    a. Where modelling can demonstrate that the discharge techniques and operational parameters (e.g. depth, rate and duration) are such that no impact to Scott Reef shallow water benthic communities and habitats (<75 m water depth) are predicted, drilling will be undertaken accordingly.
    b. For those scenarios where modelling suggests impact to Scott Reef shallow water benthic communities and habitats (<75 m water depth) may occur, alternative drilling discharge techniques and operational parameters (e.g. depth, rate and duration) will be assessed and selected to avoid potential impacts.
2. Where bottom-hole section drilling discharges are planned to be undertaken at the specified drill centre locations based on outcomes from the drilling discharge modelling, monitoring at discharge source will be undertaken to verify the model predictions and ensure they are appropriately conservative.
3. For those scenarios where modelling predicts impact to Scott Reef shallow water benthic communities and habitats (<75 m water depth), and no alternative discharge techniques and operational parameters are available, then the relevant drilling or completions discharges predicted to cause the impact will be transported to a suitable location (e.g. at a sufficient distance from the reef or onshore) for disposal.
4. For those scenarios where verification monitoring at the discharge point indicates a potential impact to Scott Reef shallow water benthic communities and habitats (<75 m water depth), then the management of drilling or completions discharges (as predicted to cause the impact) will be addressed by transportation to a suitable location (e.g. at a sufficient distance from Scott Reef or onshore) for disposal.

These management objectives are supported by a range of both feasible and industry proven management measures.

Assessment

The impacts of drilling or completion discharges on water and sediment properties, and benthic communities are well documented. The United Kingdom Offshore Operators Association (UKOOA) sponsored an extensive initiative to assess the issue of cuttings piles in the North Sea from operations between 1970 and 2000 (Danielsson et al., 2005). More recently, the International Association of Oil and Gas Producers (IOGP) published a report which reviews scientific literature on the fate and effects of ocean discharge of drill cuttings and associated drilling fluids from offshore oil and gas operations (IOGP, 2016). Drill cuttings have been studied specifically on the NWS of Australia (Oliver and Fisher, 1999; SKM, 2007). The effects of turbidity and sediment deposition on sensitive ecological receptors such as corals have also been the subject of many peer-reviewed studies (e.g. Fabricius, 2005).

Drilling or completions discharges have the potential to impact the marine environment through:

- temporary increase in TSS in the water column
- attenuation of light penetration as an indirect consequence of the elevation of TSS and the rate of sedimentation
- sediment deposition to the seabed leading to the alteration of the physio-chemical composition of sediments, and burial and potential smothering effects to sessile benthic biota
- potential contamination and toxicity effects to benthic and in-water biota from drilling fluids.

It should be noted that the following assessment is restricted to potential impacts to deepwater habitats around Scott Reef, given Woodside's commitment (see Section 8.2.6) to not undertake sea surface discharge from the bottom-hole sections that could potentially affect Scott Reef shallow water benthic habitats (<75 m water depth).

Change in sediment quality

Cuttings discharged at the seabed will result in localised cuttings piles on the seabed surrounding the wellhead, with a greater spread of cuttings expected to occur down current from the well site. Sediment quality can be impacted by drilling or completions discharges as the drill cuttings alter the particle size distribution and physico-chemical composition of sediments and from the introduction of contaminants (e.g. hydrocarbons and metals) from drilling fluids. This in turn can have an impact on benthic communities through sediment deposition causing burial and smothering, or toxicity effects from drilling fluids.

The modelling indicates that sediment deposition would potentially occur to a distance in the order of a couple of hundred metres from each well location (in the direction of the prevailing current). This assessment aligns with several studies which indicate that the spread of cuttings can be expected to be up to about 150 m from the discharge location (IOGP, 2016).

Change in water quality

The discharge of drill cuttings and unrecoverable fluids is expected to increase turbidity and TSS levels in the water column. Drilling or completions discharges are generally intermittent and of short duration during the drilling of a well. Nelson et al (2016) identified <10 mg/L as no effect or sub lethal minimal effect concentration, with Boesch and Rabalais (1987) demonstrating that surface discharges are likely to be confined to within 350 m - 1,500 m downstream from the discharge location.

The modelling (Section 6.3.15.3 of the draft EIS/ERD) indicates that both seabed and surface drilling discharges would result in impacts to water quality as a result of elevations in TSS and the introduction of low toxicity contaminants. This reduction in water quality will be temporary (i.e. limited to the duration of the activity, restricted to deep water (for Torosa drill centres in the State Proposal Area) and subject to rapid dispersion and dilution by prevailing currents, due to the open oceanic waters of the State Proposal Area.

Overall, given the predicted rapid dispersion of suspended sediments within the open ocean environment of the State Proposal Area, the short period of intermittent discharge and the generally low concentration of TSS within tens of metres of the discharge, any change in water quality and sediment associated with drill cutting discharge are expected to be temporary with a slight effect and with no long-term reduction in the environmental values of the State Proposal Area. In addition, the implementation of the proposed management approach for the proposed Torosa drill centres should ensure that impacts to Scott Reef shallow water benthic habitats (<75 m depth) are avoided.

Further discussion on the potential impacts to benthic habitats from drill cuttings discharge is presented in Section 8.3.5.

8.2.4.9 Marine discharges: subsea control fluids

A detailed description of the proposed discharge of subsea control fluids and an assessment of the potential impacts associated with the discharge is provided in Section 6.3.16 of the draft EIS/ERD.

The subsea hydraulic control system will have high pressure (HP) and low pressure (LP) circuits. The HP system will operate the downhole safety valve and the LP system will operate all other subsea valves. An open loop subsea control system will be adopted for the HP control systems, whereby the control fluid is pressurised on the FPSO facilities by the hydraulic accumulators and delivered to subsea valves via umbilicals. For the LP control system, a hybrid solution will be used.

The open loop HP hydraulic system will discharge a small amount (0.1 L) at the Christmas tree when testing or operating the downhole safety valve. The release will be at the wellhead subsea control module, typically at 350 m water depth or greater. The hybrid LP hydraulic system will utilise a contingency injection line in the umbilical in order to achieve a closed loop configuration. This hybrid system has no planned discharges and will only release hydraulic fluid if the system leaks or the contingency injection line is required due to failure of the primary injection line.

Control fluids are sourced from proprietary suppliers and are composed of low toxicity, water-based fluids. The specific control fluid has not yet been selected; however, such fluids are typically waterbased with additives such as monoethylene glycol (MEG) (usually about 40% of the total volume), lubricants, corrosion inhibitors, biocides and surfactants.

During drilling activities, control fluids will be discharged during function and pressure testing of the BOP control system. The maximum volume of control fluid that will be released to the marine environment per manifold is 1,900 L per year of water-based fluid containing ~3% active ingredient (40–68 L of control fluid additive).

Given the small volumes and solubility of the proposed water-based discharges, it is anticipated the fluids would be rapidly diluted (within tens of metres) in the prevailing currents adjacent to the discharge location on the seabed. Hence, the intermittent discharge of small volumes of subsea control fluid may result in a reduction in water quality that will be temporary (limited to the duration of the activity), restricted to deep water; and subject to rapid dispersion and dilution by prevailing currents due to the open oceanic waters of the State Proposal Area.

Due to the expected rapid dispersion and dilution by prevailing currents, and fact that discharged subsea fluid is not predicted to accumulate in sediments, no lasting change to sediment quality is predicted.

Given the minimum water depth at potential discharge locations (greater than 350 m), and the expected rapid dispersion and dilution by prevailing currents, exposure of plankton to the discharge is predicted to be negligible. In addition, the wide spread nature and rapid turn-over of plankton populations leading to relatively quick recovery times, ensures that any impact on local communities would be expected to recover relatively quickly (within weeks or months) (ITOPF, 2011).

Given this and the sparse nature of the deepwater benthic habitats in the State Proposal Area, no impacts to biota are predicted. Further, given the distance from the subsea infrastructure to Scott Reef and the depth of the discharge, this reduction in water quality is not expected to result in any lasting impacts to the environmental values of the State Proposal Area, including the Scott Reef system.

8.2.4.10 Marine discharges: hydrotest fluid

Hydrotest fluids are used for two distinct purposes; testing of the integrity of the flowlines and for preservation of the flowlines prior to the introduction of reservoir fluids. Hydrotest fluids may consist of a combination of seawater, biocides, corrosion inhibitors, oxygen scavenger, MEG and fluorescent dye.

The period of time the hydrotest fluid is left within the infrastructure as a preservation fluid will depend on the type of fluid selected and the proposed Browse to NWS Project schedule for construction and installation activities. It may be necessary to discharge and replace the hydrotest fluid if it is not providing an effective mitigation against integrity threats.

For the SURF infrastructure, the flowline and riser hydrotest fluid will most likely be returned to the FPSO facility and then discharged to sea in Commonwealth waters. However, discharge may occur in deep water at the manifolds or riser base FLETS for rigid flowlines.

For flowlines where the manifold is in the State Proposal Area, discharge will occur at the FPSO location (either from the FPSO or from the riser base FLETS) in order to maximise distance of the discharge from Scott Reef. However, for flowlines which are terminated at both ends within the State Proposal Area (specifically for TRE and TRF manifolds only), discharge of flowline hydrotest fluid in the State Proposal Area may be unavoidable. Given that the TRE and TRF manifolds are daisy-chain connected to other manifolds in the State Proposal Area and are not part of Torosa Phase 1 RFSU equipment, future engineering will consider the viability of alternatives to flowline hydrotest fluid discharge in the State Proposal Area, which will be described in a future Environment Plans. Minor hydrotest discharges associated with smaller pieces of subsea equipment may also occur in situ.

For the SURF flowlines (including those in the State Proposal Area), hydrotest fluids may consist of chemically treated seawater or a MEG/water mixture. The combination of constituents for the SURF flowlines are dependent on the flowline material type and on the period of preservation required.[1]

Hydrotest fluid volumes being discharged to the marine environment will vary depending on the flowline section to be tested. Volumes are estimated to be up to approximately 950 m^3 of hydrotest fluid for the TRE flowline and up to approximately 250 m^3 for TRF flowline. A subsea flowline hydrotest discharge is likely to take less than a day to complete. These discharges will occur for each piece of infrastructure during pre-commissioning.

---

[1] *While the majority of subsea infrastructure will be flooded with hydrotest fluid post installation, some components will be pre-flooded with hydrotest fluid prior to installation.*

Previous modelling of SURF infrastructure

The size of the mixing zone associated with a hydrotest discharge from flowlines is dependent on the discharge characteristics (e.g. rate, volume, density etc.) and prevailing hydrodynamics. Woodside has previously performed hydrotest modelling for a range of discharge rates (4.8 m^3/min, 3.7 m^3/min, 1.85 m^3/min and 1.5 m^3/min), in water depths ranging from 130 m to 830 m on the North West Shelf, which is considered appropriate to support the impact assessment, in recognition that further hydrotest modelling will be completed to support the relevant Environment Plan.

The nearfield dispersion modelling indicated that due to the momentum of the discharges a turbulent mixing zone is created in the immediate vicinity of the discharge points. Following this initial mixing, the negatively-buoyant plumes are predicted to travel laterally in the water column and remain close to the seabed.

The far-field dispersion modelling indicated that based on an in-pipe chemical concentration of 600 ppm, the plume would achieve 600 dilutions to dilute to below 1 ppm (based on LC50 over 96 hours) in proximity to the discharge location, ranging at a distance from 50 m (130 m water depth; 1.5 m^3/min; summer; 95th percentile) to 300 m (844 m water depth; 4.8 m^3/min; summer; 95th percentile) downstream of the discharge point. Given the negative buoyancy of the plume, bathymetry of the location (steep reef slopes surrounding the discharge location), and lack of upwelling processes from the depth of discharge, regardless of the size of the mixing zone the zone of influence will remain restricted to depth and avoid Scott Reef shallow water benthic habitat (<75 m bathymetry).

While the modelling for the planned dewatering discharges are not directly comparable with regards to depth of discharge, the typical density and nearfield mixing profile near the seabed provides a good indication that potential impacts to benthic communities, fish or pelagic invertebrates would be limited and restricted to the deepwater location where the SURF infrastructure is located. Noting the results presented are also conservative as they assume that no processes other than dilution would reduce the source concentrations over time, and therefore can be considered as conservative outcomes.

MODU

The temporary production system on the MODU will be hydrotested for well unloading activities. This will be conducted using hydrotest fluids, whereby the temporary production system on the MODU flowlines will be pressurised with fluids and the pressure will be monitored to detect leaks, prior to discharge of the hydrotest fluids.

Contingency discharge

Contingency discharge of hydrotest fluids during construction (e.g. buckling and leaking of the flowline during installation) are possible but are a contingent planned activity to be undertaken due to an unplanned event. The requirement for contingency discharge is determined by the technical design specifications and performance criteria of the subsea infrastructure. Should these be compromised (i.e. failed welding joint) various repair strategies will be assessed and a decision made should the contingency be required. The volume of hydrotest fluid that would be discharged in the event of a wet buckle depends on the location, extent and repair method. The planned hydrotest discharge would not occur at the same time as contingency discharge. As such, it is considered that the impacts relating to this contingency activity (as a worst case) are consistent with the below assessment and no cumulative impacts would occur.

Hydrotest fluid toxicity

Due to the proposed chemical additives with the hydrotest fluid (i.e. biocides, corrosion inhibitors, oxygen scavenger, fluorescent dyes and MEG), the discharges have the potential to impact sensitive receptors within the discharge area of influence, primarily through toxicological effects ranging from the inhibition of key biological processes (e.g. reproduction) to mortality. In considering the potential impacts to receptors it should be noted that the activity is planned during commissioning, with no ongoing discharge of hydrotest fluids during the normal operations.

MEG, which may be used in the SURF flowlines, is commonly used as a hydrate inhibitor within oil and gas developments. The chemical itself is clear and colourless, with a low volatility and miscible with water; however, no hydrolysis of the compound is expected in surface waters (WHO, 2000). MEG is listed as ‘E’ category fluids under the Offshore Chemical Notification Scheme (OCNS) and are listed on the Oslo Paris Commission (OSPAR) PLONOR (‘pose little or no risk to the environment’) list. In addition, the compound has little or no capacity to bind to particulates and will be mobile in soil (WHO, 2000). Rapid degradation has been reported in surface waters, with a generally low toxicity to aquatic organisms. Direct toxicity testing of neat MEG, on eight, mainly tropical species, representing seven taxonomic groups, established the lowest no observable effect concentration (NOEC) for sea urchin fertilisation of 130 mg/L (Jacobs, 2019). While MEG may result in highly localised, temporary and minor change in water quality in the immediate vicinity of the discharge point, it will dilute rapidly below levels that could cause impacts to marine biota.

Fluorescein dye is typically selected for use as a leak detection dye due to its low toxicity, availability, low cost, water solubility and stability, and ease of detection. In addition, rapid breakdown of fluorescein dye following exposure to sunlight suggests that concentrations likely to be encountered by organisms in the receiving environment would be low (Walthall and Stark, 1999). During discharge the dye may result in a temporary localised discoloration in the immediate vicinity of the discharge point on the seabed; however, as the dye is water soluble, it will rapidly dilute in the marine environment with no anticipated toxicity effects on marine organisms.

Due to the addition of oxygen scavengers within the hydrotest fluid, the discharge will have a lower dissolved oxygen level than the surrounding seawater. However, oxygen levels are anticipated to rapidly achieve background levels soon after discharge with any impacts on the surrounding waters expected to be temporary and highly localised. In addition, as the hydrotest fluid is planned to remain inside the pipelines and infrastructure for several months, the toxicity of residual chemicals will be markedly reduced over time, through natural decay and degradation, further reducing the potential impacts associated with the discharge.

Assessment of impacts

The presence of chemical additives in discharged hydrotest fluids is expected to result in a temporary decline in water quality around the discharge locations. For the SURF discharges, the plume is expected to travel in close proximity to the seabed which means the temporary change in water quality will be restricted to deep waters. As outlined in the draft EIS/ERD **Section 5.2.5.7**, while there is some evidence of localised intrusions of cooler water around the western and eastern entrances to the channel between North and South Scott Reef during spring tides, there is no evidence of persistent upwelling or downwelling currents around Scott Reef (Green et al., 2019b). Hence, the discharge would be subject to rapid dispersion and dilution by prevailing currents, due to the open oceanic waters of the Project Area. In addition, the low toxicity hydrotest fluids will degrade and decay once released. As such no lasting effect on water quality is predicted.

8.2.4.11 Unplanned marine discharges: hazardous and non-hazardous inorganic waste

A detailed assessment of the potential risks associated with the unplanned discharge of hazardous and non-hazardous inorganic wastes is provided in **Section 6.3.14** of the draft EIS/ERD.

There is no planned discharge of hazardous or non-hazardous inorganic waste within the State Proposal Area and, as such, no impact to marine environmental quality is expected from such discharge. As described in **Section 6.3.14** of the draft EIS/ERD, however, an unplanned loss of hazardous and non-hazardous inorganic waste during transfer, handling and storage may be caused by human error, equipment or poor weather conditions, resulting in an accidental release of waste to the State Proposal Area.

In the event of an accidental discharge to the marine environment, discharged materials in liquid or sludge form would be subject to rapid dispersion and dilution by prevailing currents, due to the open oceanic waters of the State Proposal Area. Given the typically small volumes and temporary duration of accidental discharge events, these would result in a temporary and highly localised reduction in water quality. Under normal operating conditions, drilling and vessel activity will be limited to the deep waters in proximity to the location of the proposed development wells and subsea infrastructure so any accidental discharge to the marine environment is unlikely to impact the Scott Reef system.

8.2.4.12 Unplanned hydrocarbon releases

A detailed assessment of the potential risks associated with unplanned hydrocarbon releases is provided in **Section 6.3.21** of the draft EIS/ERD. Quantitative hydrocarbon spill modelling of various worst-case hydrocarbon release scenarios is presented in **Section 6.3.21.3** of the draft EIS/ERD. This included modelling of a loss of well integrity scenario at the TRA-C well (Scenario 1), which represents the worst-case scenario for activities within the State Proposal Area. The summarised result of the modelling of Scenario 1 are presented in **Table 6-158** and **Figure 6-51** of the draft EIS/ERD.

Based on the outcomes of quantitative spill modelling, hydrocarbon spills resulting from the proposed Browse to NWS Project have the potential to significantly impact regional water and sediment quality including within the State Proposal Area. However, the occurrence of hydrocarbon spills is considered highly unlikely and the extent of impacts would depend on the exposure concentration, duration and degree of weathering of the hydrocarbons.

8.2.4.13 Cumulative impacts

Given the distance of the State Proposal Area from other operating developments in the region, it is not considered credible that cumulative impacts from the proposed Browse to NWS Project (or the Proposal) and other developments will occur.

With respect to the Commonwealth waters component of the proposed Browse to NWS Project, other than potentially hydrotest discharges, it is not expected that planned marine discharges to Commonwealth waters will contribute to impacts on marine environmental quality within the State Proposal Area (**Chapter 6** of the draft EIS/ERD). Operational discharges (i.e. PW and cooling water) from the FPSO will be managed in Commonwealth waters to ensure the defined threshold values (e.g. 99% species protection or no effect concentrations) at the State waters 3 nm boundary are met 95% of the time, based on dispersion modelling results.

While not considered the base-case, the potential discharged of hydrotest fluids from the BTL at the Torosa pipeline end terminal (Section 6.3.17 of the draft EIS/ERD) may result in a temporary reduction in water quality within the State Proposal Area. Modelling (Section 6.3.17.3 of the draft EIS/ERD) indicates this would be restricted to deep waters surrounding the pipeline end terminal (>400 m depth). Given this, and the fact this discharge would be a one-off event that would occur prior to the commencement of operations, the discharge of hydrotest fluid from the BTL at the Torosa PLET would not be expected to contribute significantly to cumulative impacts to marine environmental quality within the State Proposal Area.

8.2.5 Assessment of Impacts

Reductions in water quality and sediment quality are predicted to occur in the State Proposal Area as a result of increased turbidity and the introduction of contaminants via marine discharges. These impacts are predicted to arise primarily from the discharge of drill cuttings and fluids during development drilling, with less significant impacts predicted to occur throughout the duration of the proposed Browse to NWS Project activities (e.g. through subsea discharges from the subsea infrastructure).

There is a large body of knowledge indicating a discharge of cuttings with adhered fluids dilutes rapidly. These studies have found that that within 100 m of the discharge point, a drilling cuttings and fluid plume released at the surface will have diluted by a factor of at least 10,000, while J.M. Neff (2005) stated that in well-mixed oceans waters (as is likely to be the case within the drilling area), drilling fluid was diluted by more than 100-fold within 10 m of the discharge.

The majority of planned marine discharges would be subject to rapid dispersion and dilution by prevailing currents, due to the open oceanic waters of the State Proposal Area. As such, reductions in water and sediment quality would be temporary and highly localised, with no subsequent impact to marine biota predicted. The exception to this would be the discharge of drill cuttings that would result in the smothering of benthic biota in the immediate vicinity (within a distance in the order of 200 m) of the drilling locations.

Given the proposed location of the wells and subsea infrastructure will be in deep waters (>300 m), away from Scott Reef and that under normal operating conditions the drilling and vessel activity will be limited to the immediate vicinity of the subsea infrastructure, it is considered unlikely that marine discharges will impact Scott Reef shallow water benthic communities and habitats (<75 m water depth). In accordance with the precautionary principle, however, given the potential sensitivities of Scott Reef benthic communities and habitats to sedimentation from surface drill cuttings discharges, Woodside has committed to managing the discharges of drill cuttings and fluids at TRA, TRD, TRE and TRF drill centre locations in such a manner that impacts to Scott Reef shallow water benthic communities and habitats (<75 m water depth) are avoided. Section 8.2.6 outlines a range of proven mitigation measures capable of achieving this outcome.

In summary, given the low toxicity of the discharges, the localised scale and temporary nature of potential changes to water and sediment quality, these changes are not expected to result in any subsequent impacts to biota or the environmental values of the Scott Reef system. Impacts will be largely confined to the benign deep-water seabed between North and South Scott Reef. No long-term change in water or sediment quality or last adverse impacts to biota is expected to occur and aside from the drill cuttings accumulation in the immediate vicinity of the wells, no lasting changes to the physical or chemical properties of waters and sediments relative to a natural state are predicted.

Given no lasting impacts are expected to water quality or biota, no subsequent impact to State managed fisheries are expected. In addition, the localised and temporary nature of the predicted reduction in water and sediment quality mean that no impacts to State marine parks (the closest being over 400 km from the State Proposal Area) are anticipated to occur. As no impacts to the Scott Reef system are expected, no impacts are expected to the Scott Reef Nature Reserve.

Given the minimal extent and magnitude of changes to marine environmental quality within the State Proposal Area as a result of the proposed Browse to NWS Project (or Proposal), impacts are expected to be consistent with the EPA objective for the environmental factor - marine environmental quality.

8.2.6 Mitigation

Chapter 8 of the draft EIS/ERD presents the overarching HSE management approach Woodside will implement for the proposed Browse to NWS Project.

Environmental Quality Management Plan

As recommended in the WA EPA Technical Guidance – Protecting the Quality of Western Australia's Marine Environment (EPA, 2016c), an Environmental Quality Management Plan (EQMP) will be prepared and implemented for the Proposal. The EQMP will only apply to the State Proposal Area. The EQMP will be developed using the principles and approaches outlined in the EPA's technical guidance.

The EPA's technical guidance outlines the following elements within an Environmental Quality Management Framework (EPA, 2016c):

- **Environmental Values (EVs):** These are values or uses of the environment that are important for a healthy ecosystem or for public benefit, welfare, safety or health and which require protection from the effects of pollution, waste discharges and deposits.

- **Environmental Quality Objectives (EQOs):** These are high level management objectives that describe what must be achieved to protect each EV.
- **Levels of Ecological Protection (LEPs):** Four levels of ecological protection (LEPs) are provided for the EQO maintenance of ecosystem integrity so that areas identified as important for conservation and biodiversity protection can be maintained in their natural state while recognising that in other parts of the marine environment there are societal uses that may preclude a high level of ecological protection from being achieved (e.g. port operations or use of marine waters for waste disposal). LEPs are not defined by current condition but are intended to represent long-term objectives for environmental quality.
- **Environmental Quality Criteria (EQC):** These represent scientifically based limits of acceptable change to a measurable environmental quality indicator that is important for the protection of the associated EV. EQC are divided into relatively simple and easy to measure environmental quality guidelines (EQGs) and more robust environmental quality standards (EQSs).

Environmental Values, EQOs and LEPs for the State Proposal Area component of the proposed Browse to NWS Project have been identified as part of the development of the draft EIS/ERD. When determining the proposed LEPs, consideration has been given to potential impacts to marine environmental quality during construction, commissioning and operations, and the planned staged development of the proposed Browse to NWS Project, where construction and commissioning activities such as drilling and completions of future drill centres may occur simultaneously with operations. As such, separate LEPs have been proposed for construction activities (including commissioning) and for operations. The following LEPs are proposed:

Construction activities

- Moderate LEP – Moderate LEPs are proposed for all areas within a 1,000 m radius of each drill centre and 500 m around all subsea infrastructure. A moderate LEP has been proposed in this area given the predicted deposition of drill cuttings above ecological thresholds for a radius in the order of a couple of hundred meters from each well, the discharge of cement for a radius of approximately 50 m from each well; the installation of the subsea infrastructure (including seabed preparation); and one-off hydrotest fluid discharge from the flowlines.
- High LEP - A high LEP is proposed for the deep waters of the State Proposal Area where the subsea infrastructure will be located (except where designated a moderate LEP). A high LEP is also proposed along the eastern edge of the State Proposal Area where there is potential for one off hydrotest discharge from the BTL (in Commonwealth waters) to temporarily incur into the State Proposal Area. Seabed disturbance may occur from anchoring within the high LEP.
- Maximum LEP - A maximum LEP is proposed for all other areas within the State Proposal Area. This includes all Scott Reef shallow water benthic communities and habitats (<75 m water depth).

Operations

- Moderate LEP – Moderate LEPs are proposed for all areas within a 1,000 m radius of each drill centre. A moderate LEP has been proposed in these areas given the predicted deposition of drill cuttings and cement during construction, as well as the physical presence of the wells and manifolds and subsea fluid discharge from the wells during operations.
- High LEP - A high LEP is proposed for the deep waters of the State Proposal Area where the subsea infrastructure will be located (except where designated a moderate LEP).
- Maximum LEP - A maximum LEP is proposed for all other areas within the State Proposal Area. This includes all Scott Reef shallow water benthic communities and habitats (<75 m water depth).

The Proposed LEPs are shown in Figure 8-1 and Figure 8-2.

The limits of acceptable change for each of the LEPs are detailed in Table 8-4.

Table 8-4 Limits of Acceptable Change to State Proposal Area Marine Environmental Quality

Key elements	Limits of acceptable change	Maximum LEP	High LEP	Moderate LEP
Ecosystem processes (e.g. primary production, nutrients cycles, food chains)	Ecosystem processes are maintained within the limits of natural variation (no detectable change)	✓	✓	
	Small changes in rates, but not types of ecosystem processes			✓
Biodiversity (e.g. variety and types of naturally occurring marine life)	Biodiversity as measured on both local and regional scales remains at natural levels (no detectable change)	✓	✓	✓
Abundance and biomass of marine life (e.g. number or density of individual animals, the total weight of plants)	Abundances and biomasses of marine life vary within natural limits (no detectable change)	✓	✓	
	Small changes in abundances and/or biomasses of marine life			✓
The quality of water, biota and sediment (e.g. types and levels of contaminants such as heavy metals, dissolved oxygen content, water clarity)	Levels of contaminants and other measures of quality remain within limits of natural variation (no detectable changes)	✓		
	Small detectable changes beyond limits of natural variation but no resultant effect on biota		✓	
	Moderate changes beyond limits of natural variation but not to exceed specified criteria			✓

The purpose of the EQMP will be to detail how the EQO outlined in Table 8-4 will be met, including planned management, monitoring and reporting. In accordance with the EPA's technical guidance (EPA, 2016) the EQMP will include:

- a description of the system to be monitored
- the pressures or threats to environmental quality
- an objective outlining the reason for monitoring and management
- duration of the monitoring program
- the indicators to be measured with a rationale for their use
- monitoring/sampling methodology and rationale (including site locations, frequency, depth, equipment, etc.)
- analytical methods and limits of reporting for samples
- clear, measurable and auditable EQC for each indicator and the statistical methods for interpreting monitoring data against the EQC
- the actions triggered when an EQG is exceeded
- management responses triggered when an EQS is exceeded
- reporting mechanisms and timing.

Specific proposed measures to mitigate and manage unavoidable impacts from planned activities and reduce the environmental risk associated with unplanned events and incidents are presented in Chapter 6 of this draft EIS/ERD and these will be incorporated into the EQMP where relevant. Measures presented in the draft EIS/ERD will also be incorporated into activity-specific Environment Plans to be submitted for acceptance by DMIRS prior to the activity commencing within the State Proposal Area.

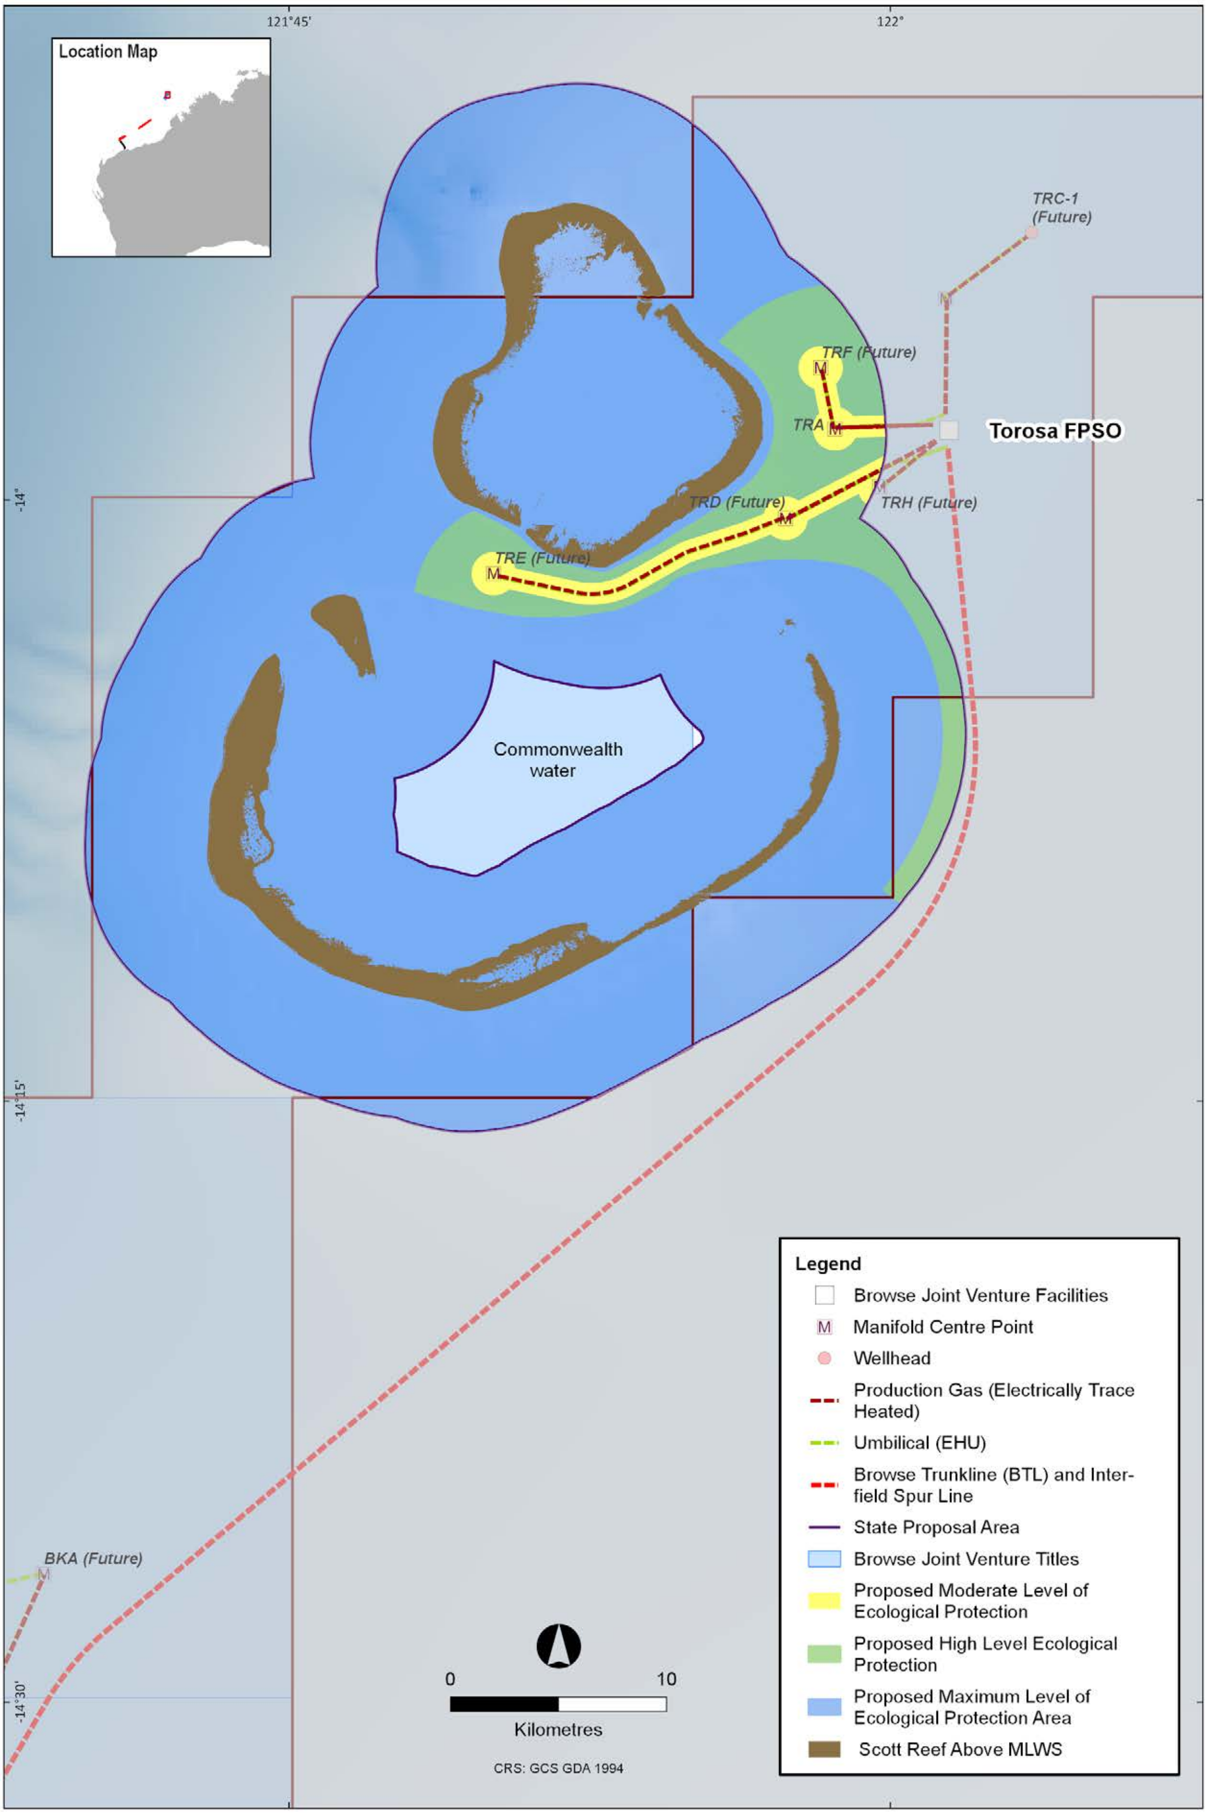

Figure 8-1 Proposed State Proposal Area Levels of Ecological Protection (LEPs) – Construction activities

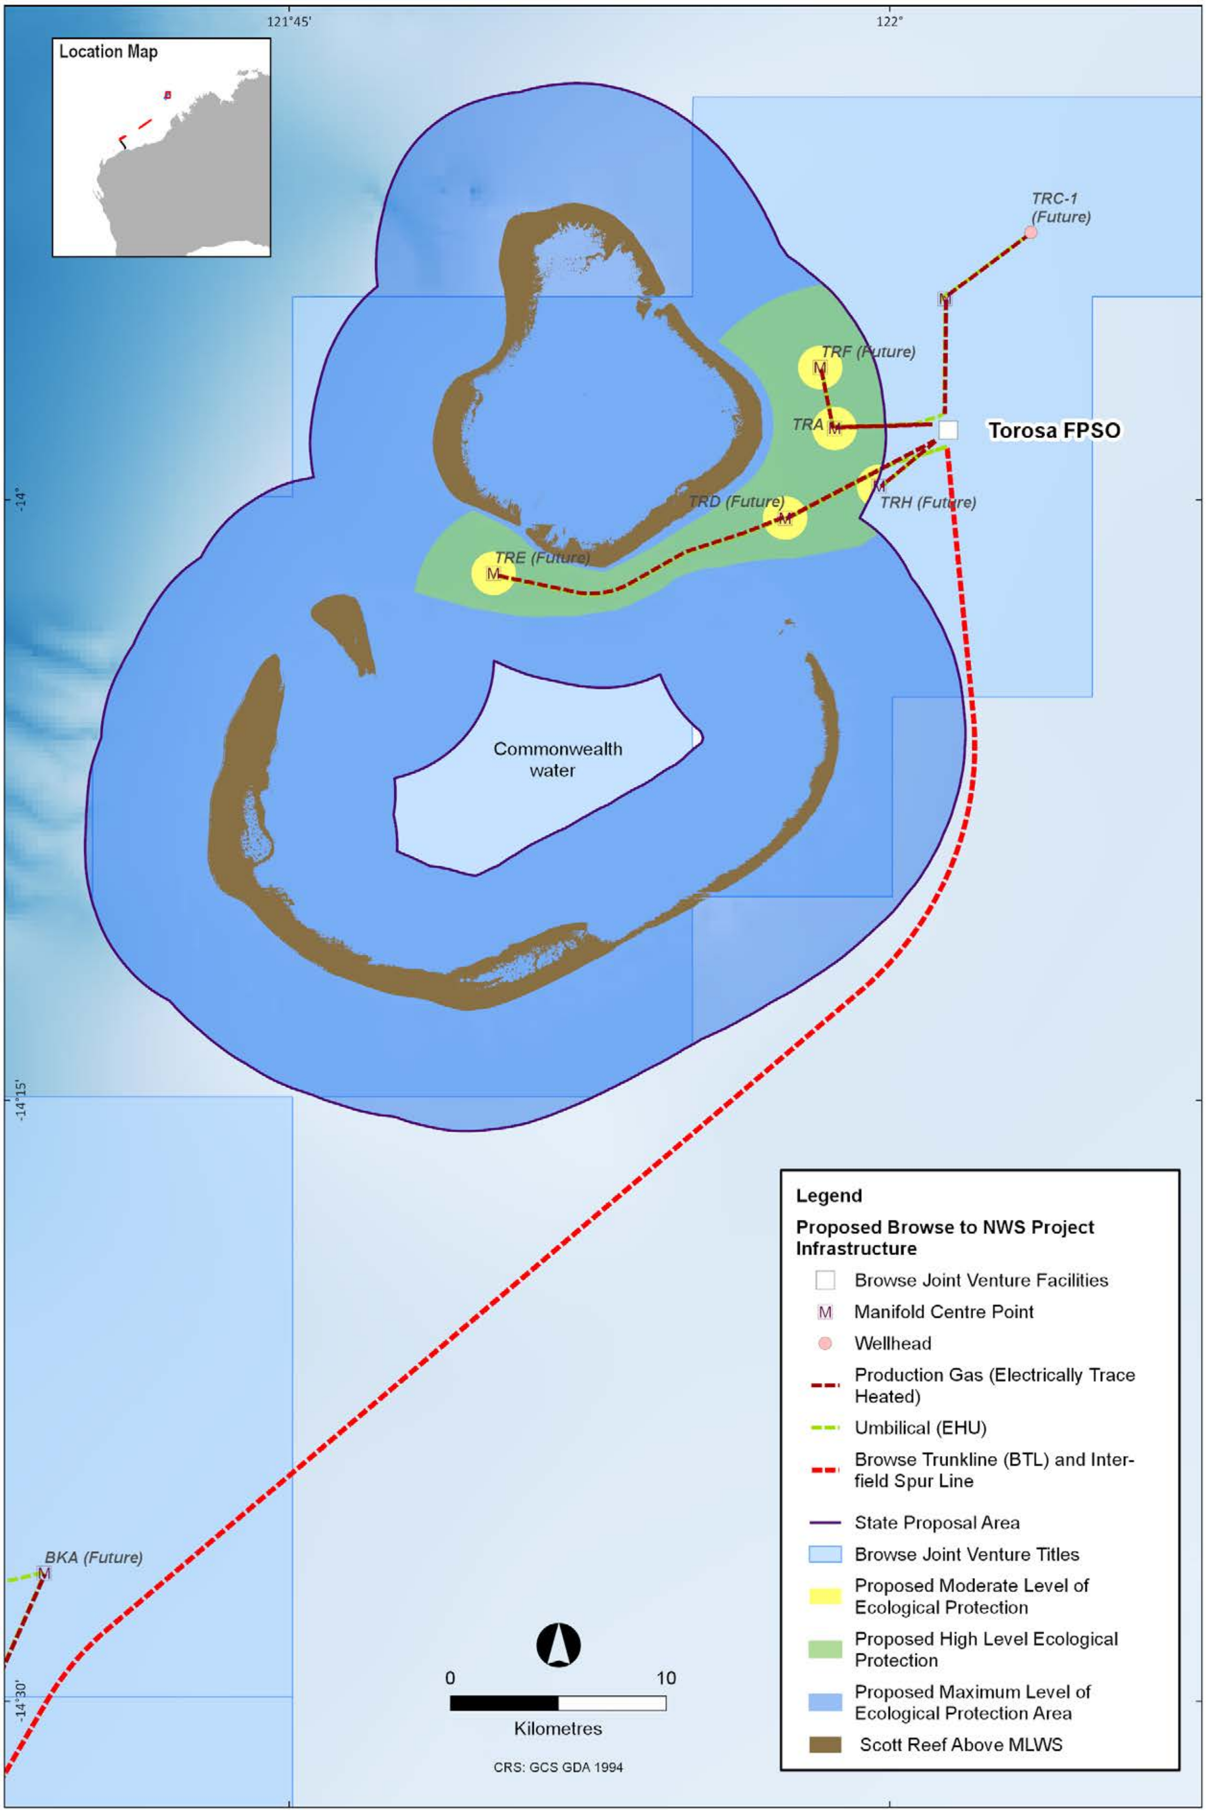

Figure 8-2 Proposed State Proposal Area Levels of Ecological Protection (LEPs) – Operations

8.2.7 Predicted Outcome

Impacts to marine environmental quality within the State Proposal Area have been reduced by locating the FPSO facilities, BTL and inter-field spur line outside the State Proposal Area and siting infrastructure within the State Proposal Area in deep waters off Scott Reef.

Impacts will be further reduced by implementing mitigation and management measures, the majority of which are standard maritime and offshore oil and gas industry practice. However, given the potential sensitivities of Scott Reef shallow water benthic communities and habitats to sedimentation from drilling discharges, Woodside has committed to managing the drilling discharges (in particular bottom hole discharges) at drill centre locations in the State Proposal Area (i.e. TRA, TRD, TRE and TRF) in such a manner that avoids impacts to Scott Reef shallow water benthic communities and habitats (<75 m water depth) (refer to **Section 8.2.6**). Implementation of this management approach will be assured through activity specific Environment Plan(s) under Petroleum Legislation.

Taking proposed mitigation and management measures into account and considering the limited scope and scale of the Proposal (with no permanent surface facility or vessel presence in the State Proposal Area) plus the overall phasing of Proposal, impacts to water quality, sediments and biota as a result of the Proposal are not predicted to result in any reduction of the environmental values of the Scott Reef shallow water benthic communities and habitats (<75m water depth).

As described in **Section 8.2.6**, it is expected a maximum LEP will be achieved in the majority of the State Proposal Area during construction and operations. A high LEP will be achieved for the deep waters of the State Proposal Area where subsea infrastructure will be located, except where a moderate LEP is proposed within a 1000 m radius of each drill centre during construction and operations; and 500 m around subsea infrastructure during construction. Further, an area of moderate LEP is proposed during construction where the potential discharge of hydrotest fluid from the BTL (in Commonwealth waters), may incur into the State Proposal Area. An EQMP will be prepared and implemented to achieve this outcome.

The EPA Technical Guidance for Protecting the Quality of Western Australia's Marine Environment (EPA, 2016c) states that the objective for LEPs are:

- A maximum level of ecological protection would require activities to be managed so that there were no changes beyond natural variation in ecosystem processes, biodiversity, abundance and biomass of marine life or in the quality of water, sediment and biota.
- The objective for a high level of ecological protection is to allow for small measurable changes in the quality of water, sediment and biota, but not to a level that changes ecosystem processes, biodiversity or abundance and biomass of marine life beyond the limits of natural variation.
- A moderate level of ecological protection may be applied to relatively small areas within inner ports and adjacent to heavy industrial premises where waste discharges from current and/or historical activities may have compromised a high level of ecological protection.

Given the majority of the State Proposal Area will be maintained at a maximum or high LEP and the moderate LEP portion corresponding with deep water benign seabed, it is expected that the WA EPA environmental objective *"To maintain the quality of water, sediment and biota so that environmental values are protected"* will be achieved for the Proposal; and the predicted impacts on marine environmental quality within the State Proposal Area are considered **Acceptable**.

8.3 Key Environmental Factor – Benthic Communities and Habitat

8.3.1 EPA Objective

The EPA objective for benthic communities and habitat is *"to protect benthic communities and habitats so that biological diversity and ecological integrity are maintained"* (EPA, 2016c).

8.3.2 Policy and Guidance

The following policy and guidance have been considered in relation to the EPA environmental factor - benthic communities and habitats.

EPA Policy and Guidance

- Statement of Environmental Principles, Factors and Objectives (EPA, 2016b)
- WA EPA Environmental Factor Guideline - Benthic Communities and Habitats (EPA, 2016b)
- WA EPA Technical Guidance - Protection of Benthic Communities and Habitats (EPA, 2016c)
- Technical Guidance - Protecting the Quality of Western Australia's Marine Environment (EPA, 2016c).

Other Policy and Guidance

Australian and New Zealand Guidelines for Fresh and Marine Water Quality (ANZG 2018).

8.3.3 Receiving Environment

The characteristics of the marine environment of the Browse Development Area are described in detail in **Chapter 5** of the draft EIS/ERD. The benthic communities and habitats within the State Proposal Area can broadly be delineated into two areas, Scott Reef benthic communities and habitats and the deepwater benthic communities and habitats. As described in **Chapter 6** of the draft EIS/ERD, for the purpose of the environmental impact and risk assessment undertaken for the proposed Browse to NWS Project, Scott Reef is considered as the area above the 75 m bathymetric contour within the 3 nm State waters boundary. The deepwater communities are defined as those communities below the 75 m bathymetric contour and make up the remainder of the State Proposal Area. It should be noted that, as shown in **Figure 5-1**, all proposed subsea infrastructure will be located within the deepwater habitats away from Scott Reef. As such, no direct disturbance of the Scott Reef benthic communities and habitats will occur, with disturbance limited to the deepwater habitats of the State Proposal Area.

Scott Reef habitats and communities

The Scott Reef system consists of two shelf atolls, North Scott Reef and South Scott Reef, separated by a deep channel. The Scott Reef system is characterised by extensive benthic primary producer habitat (i.e. corals, seagrass, macroalage and filter feeders). At least 14 distinct benthic habitat types have been defined that can broadly be grouped into shallow water habitats (<30 m), deep lagoonal habitats (between 30-70 m) and deepwater slope habitats (70-500 m) (**Figure 8-3**). The shallow water habitats occupy 170.5 km^2 and 147.1 km^2 at the South and North Scott Reef, respectively, and include reef crests, flats and slopes, patch reefs and the shallow water lagoons. These habitats support more diverse coral communities than deeper waters; however, they are more susceptible to natural impacts such as thermally induced coral bleaching and cyclone damage. The deepwater lagoonal habitats of South Reef are extensive, covering approximately 289 km^2.

The Scott Reef system is largely unaffected by many of the anthropogenic stressors that affect coral reefs close to the coast, due to its isolation, distance from shore and the absence of human settlement. However, the reef and its benthic communities and habitats are not without exposure to physical disturbances and pressures including tropical cyclones, anomalous sea surface temperatures and disease.

Section 5.3.2.2 of the draft EIS/ERD provides further details on the status of the benthic communities and habitats within the Scott Reef system.

Deepwater habitats and communities

The deepwater benthic habitats of the State Proposal Area are consistent with the remainder of the Browse Development Area. Survey findings for the benthic communities inhabiting the predominantly soft sediments of the deep water benthic habitats where the subsea infrastructure will be installed demonstrated that these areas were characterised by fine sediments with infaunal polychaetes dominant and sparsely distributed epifauna observed (i.e. bryozoans, brittlestars, basketstars and sea anemones) (Gardline Marine Services Pty Ltd, 2009b). **Section 5.3.2.1** of the draft EIS/ERD provides further details of these communities and habitats.

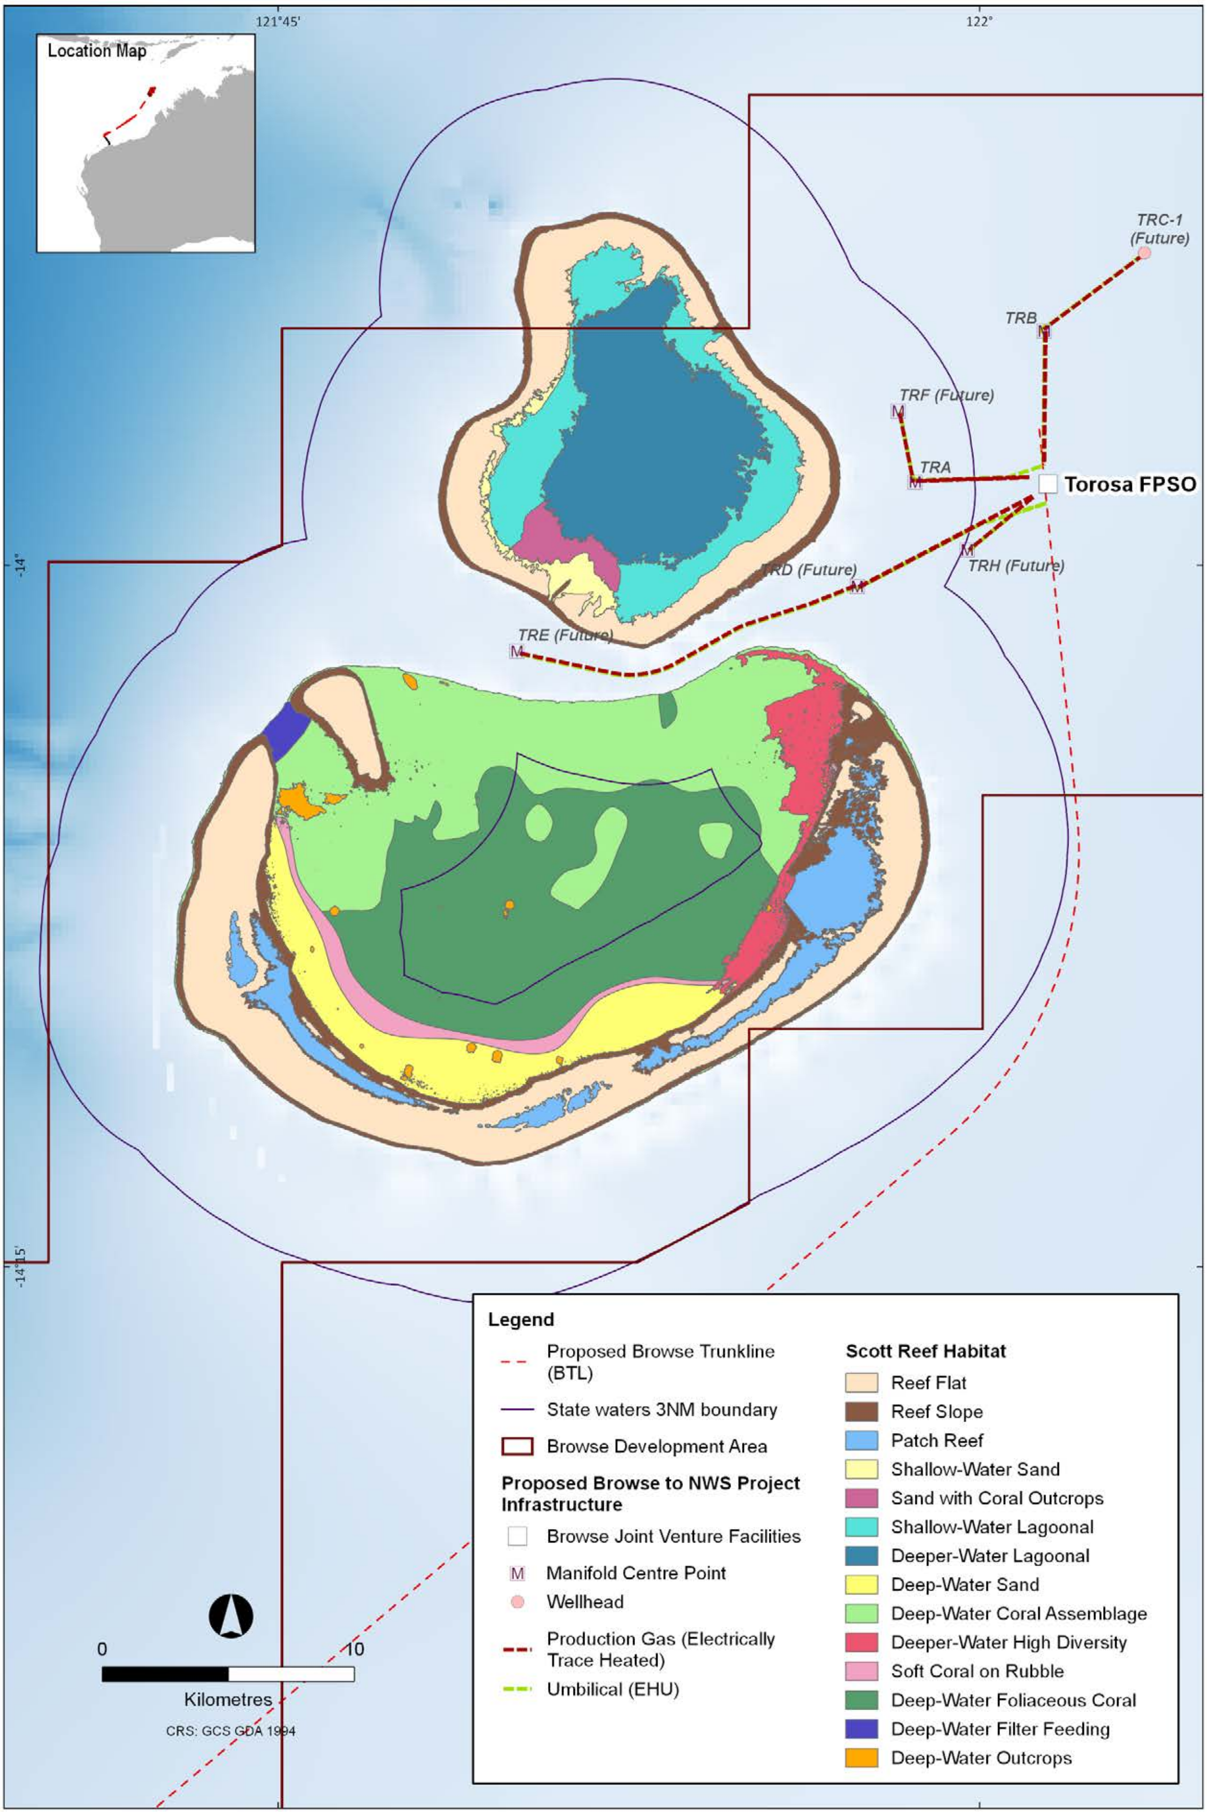

Figure 8-3 Scott Reef Habitat Map (Smith et al., 2006)

8.3.4 Potential Impacts

8.3.4.1 Summary of Identified Impacts and Risks

Table 8-5 summarises the sources of potential impact to benthic communities and habitats arising from the Proposal. Table 8-5 is followed by a detailed description of the potential direct, indirect and cumulative impacts. An assessment of the significance of these impacts on benthic communities and habitats and a conclusion on the acceptability of the impacts in relation to the EPA environmental objective is presented in Section 8.3.5.

Table 8-5: Sources of Potential Impact to Benthic Communities and Habitats from the Proposal

Aspect	Proposal Phase[1]					Source (in State jurisdiction
	Dr	I	C	O	De	
Planned (routine and non-routine activities)						
Physical presence: light emissions	✓	✓	✓	✓	✓	Project vessels, installation vessels and MODU operating in the State Proposal Area Intermittent flaring from the MODU
Physical presence: seabed disturbance and disturbance to other users	✓	✓		✓	✓	Development of the production wells Installation of subsea infrastructure Wet storage of infrastructure prior to installation MODU anchors IMR activities
Underwater noise	✓	✓	✓	✓	✓	Project vessels, installation vessels and MODU operating in the State Proposal Area VSP/DAS during well development Piling for MODU anchor installation (if required) Seabed preparation Helicopter movements
Marine discharges: sewage and sullage	✓	✓	✓	✓	✓	Project vessels, installation vessels and MODU operating in the State Proposal Area
Marine discharges: treated utility water, chemical and deck drainage	✓	✓	✓	✓	✓	Project vessels, installation vessels and MODU operating in the State Proposal Area
Marine discharges: produced water	✓					MODU during well unloading activities
Marine discharges: cooling water	✓	✓	✓	✓	✓	Project vessels, installation vessels and MODU operating in the State Proposal Area
Marine discharges: drilling and completion discharges	✓					MODU during drilling activities
Marine discharges: subsea control fluids	✓	✓	✓	✓	✓	Subsea infrastructure BOP during drilling ROVs
Marine discharges: hydrotest fluid	✓	✓	✓	✓		Temporary production system on MODU Integrity testing of subsea infrastructure
Production Activities: Seabed Subsidence				✓		Extraction of reservoir fluids
Unplanned events and incidents						
Marine discharges: hazardous and non-hazardous waste inorganic waste	✓	✓	✓	✓	✓	Project vessels, installation vessels and MODU operating in the State Proposal Area

Aspect	Proposal Phase[1]					Source (in State jurisdiction
	Dr	I	C	O	De	
Unplanned hydrocarbon releases	✓	✓	✓	✓	✓	Project vessels, installation vessels and MODU operating in the State Proposal Area Subsea infrastructure
Physical Presences (Unplanned): Invasive Marine Species	✓	✓	✓	✓	✓	Project vessels, installation vessels and MODU operating in the State Proposal Area

1 Dr = Drilling; I = Installation; C = Commissioning; O = Operation; De = Decommissioning

8.3.4.2 Physical presence: seabed disturbance

Where present, benthic epifaunal and infaunal communities in the deep waters of the State Proposal Area will be impacted by the temporary and permanent installation of physical infrastructure on the seabed, resulting in modification of habitats, smothering of biota and temporary reductions in water quality from sediment re-suspension and sedimentation. Due to the distance of the proposed subsea infrastructure to Scott Reef, no impacts to the environmental values of the Scott Reef system will occur as a result of seabed disturbance.

A detailed description of the planned seabed disturbance and an assessment of the potential impacts associated with seabed disturbance is provided in **Section 6.3.1** of the draft EIS/ERD.

The WA EPA Technical Guidance - Protection of Benthic Communities and Habitats provides the following definitions with respect to impacts to benthic communities and habitats (EPA, 2016c):

+ Permanent loss refers to direct removal or destruction of benthic communities and/or their habitats. Permanent loss of benthic communities and their associated habitats would commonly be associated with activities such as excavation or burial. In almost all cases these activities directly modify the benthic community and its habitat so significantly that the impacted community would not recover to the pre-impact state.
+ 'Serious damage' means damage to benthic communities and/or their habitats that is effectively irreversible or where any recovery, if possible, would be unlikely to occur for at least 5 years. Serious damage is most often associated with indirect effects of development activities such as alteration of natural groundwater hydrology (e.g. leading to impacts on dependent mangroves) or chronically elevated suspended sediment levels in the water column (e.g. leading to reduced benthic light and impacts on dependent seagrass or coral communities).
+ 'Reversible impacts or loss' refer to the situation where impacts or losses of benthic communities occur, but there is confidence that the community, and the ecological services it provides, will fully recover within five years.

Seabed disturbance in the State Proposal Area is expected to be approximately 4.15km^2 and will be limited to deep water habitats and communities. No disturbance of the Scott Reef shallow water benthic communities and habitats (<75 m water depth) is planned. **Table 8-6** provides an overview of the extent of seabed disturbance in the State Proposal Area. Note that these disturbance estimates include indirect disturbance from drilling discharges which are address in **Section 8.3.4.9**.

This disturbance will result in the permanent loss of up to 0.31km^2 (including 25% contingency) of deepwater habitat for the development of the wells and installation of subsea infrastructure. This is the area lost directly due to the infrastructure footprint. It should be noted that this permanent loss may be partially compensated by the creation of artificial hard substrate habitat (i.e. subsea infrastructure) which may be colonised by epifaunal organisms.

The contingency includes allowance for temporary wet storage during construction, pre lay and post lay of subsea infrastructure activities, allowance for a broader well radius for potential cementing and sedimentation, and other disturbance associated with MODU piling/anchoring (if required).The remaining 3.84 km^2 (including 25% contingency) of seabed disturbance will result from temporary indirect impact associated with wet storage of temporary infrastructure and the installation of subsea infrastructure. This will result in reversible loss of deepwater benthic habitat, with benthic biota expected to recolonise the area once the permanent infrastructure is installed and the temporary infrastructure is removed. Studies indicate that benthic infauna and epifauna recover relatively quickly, with substantial recovery in deepwater benthic communities within three to ten years (Jones et al., 2012).

Given the relatively sparse nature of the deep water benthic communities and habitats of the area to be disturbed (**Section 5.3.1.2** of the draft EIS/ERD), the small area of permanent disturbance (relative to the total area of similar habitat available regionally); and expected recolonisation of the seabed with similar benthic biota after the removal of temporary infrastructure, seabed disturbance within the deep waters of the Project Area is not predicted to impact biological diversity or ecological integrity.

Table 8-6 Indicative extent of seabed disturbance within the State Proposal Area

	Description	No.	Direct Disturbance (km²) (Permanent Loss)	Indirect Disturbance (km²) (Reversible Loss)	Total (km²)
Drilling and Completions					
Wells	Torosa	24	0.19	2.83	3.02
SURF Footprint					
Flowline network	Torosa	1	0.06	0.24	0.30
Total Expected			**0.25**	**3.07**	**3.32**
Contingency (25%)			0.06	0.77	0.83
Total (including Contingency)			**0.31**	**3.84**	**4.15**

Basis:

1. *Wells have a direct impact radius of 50 m and a total radius of 200 m.*
2. *Flowlines have a 2 m corridor direct impact and a 10 m corridor total impact.*

This estimate includes subsea disturbance from all major infrastructure sources. The contingency includes allowance for temporary wet storage during construction, pre lay and post lay of subsea infrastructure activities, allowance for a broader well radius for potential cementing and sedimentation, and other disturbance associated with piling/anchoring (if required)

8.3.4.3 Physical presence: light

Potential impacts to shallow benthic communities and habitats (i.e. corals) from light emissions are described in **Section 6.3.3** of the draft EIS/ERD. Theoretically, there is the potential for impacts to shallow water coral communities from light emissions from the MODU and vessels within the State Proposal Area, with coral colonies particularly sensitive to changes in ambient environmental conditions, with natural factors such as nocturnal moonlight cycles and daily light/dark cycles providing cues for reproduction (i.e. spawning) (Harrison and Wallace, 1990).

Light modelling results (**Section 6.3.3** of the draft EIS/ERD) indicate that Scott Reef is expected to receive light emission levels of less than 0.01 Lux from the MODU operating in the channel between North Scott Reef and South Scott Reef. Such light levels are less than a comparable full moon and therefore it is not considered that light emissions from the MODU or vessels associated with the proposed activities within the State Proposal Area will be of sufficient intensity to affect coral reproduction or spawning events. In addition, no permanent surface facilities to emit light will be present in the State Proposal Area during operations.

8.3.4.4 Underwater noise

Potential impacts to shallow benthic communities and habitats (i.e. corals) from underwater noise emissions are described in **Section 6.3.8** of the draft EIS/ERD. As discussed in **Section 6.3.8.3** of the draft EIS/ERD, Woodside's Maxima Study on seismic noise on Scott Reef estimated that corals would require received levels of PK-PK exceeding 260 dB re 1 μPa (SPL) to induce injury (Hastings, 2010). The modelling indicates that sound levels reaching Scott Reef from the proposed activities do not reach these levels and as such no impact to corals from underwater noise resulting from the proposed activities is predicted to occur. Likewise modelling of the VSP activities indicates that the sound level associated with no effect (Heyward et al., 2018) was not reached. As such, no impacts to corals are expected to occur.

8.3.4.5 Marine discharges: sewage and sullage

An assessment of the potential impact on marine environmental quality from the discharge of sewage and sullage from project vessels and the MODU is presented in **Section 8.2.4**. This assessment concluded that changes to the physical and chemical properties of the marine water would be temporary and highly localised (discharge diluted to 1% of its original concentration with 50 m). No change to the physical or chemical properties of sediments are expected due to the depth of the water where treated sewage and sullage would be discharged.

Given the water depth at the discharge locations (>300 m), it is not predicted that the this change in water quality will affect the deepwater benthic habitats of the State Proposal Area. Given the distance from the discharge to Scott Reef and rapid dispersion predicted (refer to **Section 8.2.4.4**), no effect on Scott Reef benthic communities and habitats is expected to result from the discharge of treated sewage and sullage in the State Proposal Area.

8.3.4.6 Marine discharges: treated utility water, chemical and deck drainage

An assessment of the potential impact on marine environmental quality from the discharge of treated utility water, chemical and deck drainage from project vessels, installation vessels and the MODU is presented in Section 8.2.4. This assessment concluded that treated utility water, chemical and deck discharges would result in temporary change in water quality in the immediate vicinity of the discharge. Given the water depth at the discharge location (>300 m) and distance to Scott Reef from where these discharges would occur, this temporary and highly localised change to water quality is not expected to have any impacts to either the deepwater benthic communities and habitats of the State Proposal Area or the benthic communities and habitats associated with Scott Reef.

8.3.4.7 Marine discharges: produced water

As detailed in Section 8.2.4, given the small percentage that the PW component makes of the overall discharge from the MODU during well unloading, this discharge is addressed as part of the assessment of discharges during drill cuttings and fluids.

8.3.4.8 Marine discharges: cooling water

An assessment of the potential impact on marine environmental quality from the discharge of cooling water from project vessels, installation vessels and the MODU is presented in Section 8.2.4. This assessment concluded that cooling water discharges would result in temporary change in water quality in the immediate vicinity of the discharge. Given the water depth at the discharge location (>300 m) and distance to Scott Reef from where these discharges would occur, this temporary and highly localised change to water quality is not expected to have any impacts to either the deepwater benthic communities and habitats of the State Proposal Area or the benthic communities and habitats associated with Scott Reef.

8.3.4.9 Marine discharges: drilling and completions discharges

A detailed description of the planned discharge of drill cuttings and fluids is provided in Section 8.2.4.8. Section 8.2.4.8 focuses largely on the water quality and sedimentation aspects of this impact whereas this section focuses largely on benthic fauna impacts associated with the aspect.

Change in water quality

The assessment of the potential impact on marine environmental quality (water quality, sediments and biota) from the discharge of drill cuttings and fluids from the MODU during drilling and completions activities presented in Section 8.2.4 concluded that change in to water quality (through elevated TSS and the introduction of contaminants) would be temporary and localised with no subsequent impacts to biota predicted.

Cement discharge

Once each of the top hole sections are drilled, casing will be inserted into the wellbore and secured in place by pumping cement into the annular space back to approximately 300 m above the casing shoe, which may involve a discharge of excess cement at the seabed (~80 m^3/well). Overspill of cement will permanently alter physical sediment properties immediately adjacent to the well (within <50 m). The potential disturbance area is 0.8 ha per well; giving a total potential disturbance footprint of 0.19km^2 within the State Proposal Area. This will result in the permanent loss of the benthic communities and habitats in the disturbance area.

Sediment deposition

Following the discharge of drill cuttings and fluids, the coarser fractions (sand and gravel-sized particles), will rapidly settle to the seabed. Where cuttings are discharged to the seabed, a cuttings pile will develop immediately around the well site. The nature and size of the pile will depend on a number of factors including particle size of the cuttings, tidal and current forces and water depth. Discharge of cuttings at the surface will result in a sediment plume with the dispersion and settlement of cuttings dependent on the particle sizes of cuttings, water depth, as well as the prevailing wind, tidal influence and current directions.

Potential impacts are expected to be confined to sessile biota such as sediment burrowing infauna and epifauna where present in or on the seabed in immediate proximity to the well location. Ecological impacts to such biota are predicted when sediment deposition is equal to or greater than 6.5 mm (in thickness) (IOGP, 2016). Modelling (Section 6.3.15.3 of the draft EIS/ERD) indicated that such deposition would potentially occur out from the well location to approximately 200 m (following the direction of the prevailing current). This aligns with (IOGP, 2016) review of seven studies, which indicated that the spread of drill cuttings and WBFs is expected to be up to about 150 m from the discharge location. It should also be noted that sedimentation was modelled concurrently for multiple wells at the drill centres, resulting in a likely overestimation of net sedimentation given that in reality wells will be drilled sequentially and therefore further dispersion of deposited sediments will occur in between individual well drilling activities.

This deposition may result in the reversible loss in the order of 0.12 km^2 of deepwater benthic habitat per well based on an assumption of an expected spread radius of 150 m from each well (in addition to the irreversible loss of 50 m associated with cement – described above). Balcom et al., (2012) concluded that impacts associated with the discharge of cuttings and NWBFs are minimal, with impacts highly localised to the area of the discharge. Changes to benthic communities are normally not severe. Organic enrichment can occur leading to anoxic conditions in the surface sediments and a loss of infauna species that have a low tolerance to low oxygen concentrations, and to a lesser extent chemical toxicity near the well location. These impacts are highly localised with short-term recovery that may include changes in community composition with the replacement of infauna species that are hypoxia-tolerant (IOGP et al., 2016).

Recovery of affected benthic infauna, epifauna and demersal communities is expected to occur quickly, given the short duration of sediment deposition and the widely represented benthic and demersal community composition. Jones et al., (2012) compared pre and post-drilling ROV surveys and documented physical smothering effects from WBM cuttings within 100 m of the well. Outside the area of smothering, fine sediment was visible on the seafloor up to at least 250 m from the well. After three years, there was significant removal of cuttings, particularly in the areas with relatively low initial deposition (Jones et al., 2012). The area impacted by complete cuttings cover had reduced from 90 m to 40 m from the drilling location, and faunal density within 100 m of the well had increased considerably and was no longer significantly different from conditions further away. As such, the impacts to the deepwater benthic habitats are considered reversible, with benthic biota are expected to recolonise the area rapidly on completion of the drill cuttings discharge at each well.

Based on the modelling (**Section 6.3.15.2** of the draft EIS/ERD), the sedimentation footprint associated with discharge of drilling or completions discharges at the seabed, indicates that away from the immediate area around the well (i.e. 50 m radius associated with the permanent impact from well casing cement overspill), sedimentation over the course of the drilling program would be low, equating to a thin veneer of settled drilling discharges away from the immediate deposition area around the well (in the order of 200 m from the well) which will likely be naturally reworked into surficial sediment through processes including bioturbation (US EPA, 2002). Ecological impacts in these areas are not expected for mobile benthic fauna such as crabs and shrimps or pelagic and demersal fish, given their mobility (IOGP, 2016).

These impacts are considered reversible, with benthic biota expected to recolonise once the cause of the temporary disturbance is removed. Studies indicate that benthic infauna and epifauna recover relatively quickly, with substantial recovery in deep water benthic communities within three to ten years (Jones et al., 2012). IOGP (2016) found that recovery of the benthic communities generally occurred by the recruitment of new colonising organisms and migration from undisturbed sediments, with recovery beginning shortly after the completion of drilling and well underway within a year.

The assessment of the potential impact on marine environmental quality (water quality, sediments and biota) from the discharge of drill cuttings and fluids from the MODU during drilling and completions activities presented in **Section 8.2.4** concluded that change in to water quality (through elevated TSS and the introduction of contaminants) would be temporary and localised with no subsequent impacts to biota predicted.

Summary

In summary, likely impacts to benthic communities and habitats from drill cuttings and fluids discharge and cement discharge will be restricted to the localised burial of deepwater benthic habitats and likely changes to sediment quality within the immediate vicinity each well (in the order of 200 m). However, outside this area, little to no impact to the deepwater benthic communities and habitats is expected. The proposed further modelling, assessment and selection of management measures for TRA, TRD, TRE and TRF drill centres described above will inform the drill cuttings disposal method to ensure impacts to Scott Reef benthic communities and habitats are avoided.

Overall, the localised smothering of biota associated the deepwater habitats that are well represented both in the State Proposal Area and regionally is not expected to reduce biological diversity and ecological integrity within the State Proposal Area.

8.3.4.10 Marine discharges: subsea control fluids

An assessment of the potential impact on marine environmental quality from the discharge of subsea control fluids during operation of the subsea infrastructure is presented in **Section 8.2.4**. This assessment concluded that the intermittent discharge of small volumes of subsea control fluid may result in a reduction in water quality that would be temporary (limited to the duration of the activity), restricted to deepwater (i.e. not affecting Scott Reef benthic communities or habitats) and subject to rapid dispersion and dilution by prevailing currents, due to the open oceanic waters of the State Proposal Area. While benthic biota associated with the deepwater habitats of the State Proposal Area may come into contact with these discharges, given that the discharges will disperse rapidly close to the discharge point and that any contact with the discharge with benthic biota will be of extremely short duration, it is not considered credible that toxic affects to benthic biota will occur as a result of the discharge of subsea fluids within the State Proposal Area.

8.3.4.11 Marine discharges: hydrotest fluid

A description and assessment of the potential impact on marine environmental quality from the discharge of hydrotest fluid during integrity testing of the subsea infrastructure and the temporary production system on the MODU is presented in **Section 8.2.4**. This assessment concluded that given the low volume of hydrotest fluid to be discharged, the low toxicity of the fluid, and the water depth at which the discharge will occur, hydrotest discharges within the State Proposal Area would be not expected to result in any lasting impacts to biota. As such, while modelling (Section 6.3.17 of the draft EIS/ERD) predicts that the plume would travel in close proximity to the seabed and therefore may result in localised and temporary decline in sediment quality, no lasting effect to the deepwater habitats are predicted.

As described in Section 8.2.4.10, previous modelling of hydrotest fluid discharge from SURF infrastructure has been used to inform this impact assessment. From this modelling it is concluded that given the negative buoyancy of the plume, bathymetry of the location (steep reef slopes surrounding the discharge location), and lack of upwelling processes from the depth of discharge, regardless of the size of the mixing zone the zone of influence will remain restricted to depth and avoid Scott Reef shallow water benthic habitat (<75 m bathymetry).

8.3.4.12 Production Activities: Seabed Subsidence

A detailed description of the subsea subsidence that may manifest as a result of production activities and an assessment of the potential impacts that may result is provided in Section 6.3.20 of the draft EIS/ERD. This includes peer reviewed modelling (Section 6.3.20.3 of the draft EIS/ERD) which provides a high level of confidence that any production-related subsidence at Scott Reef would be in the order of less than 10 cm over field life.

As described in Section 6.3.20 of the draft EIS/ERD, AIMS (2012) assessed the impact of net sea level rise (from subsidence and climate change induced sea level rise) and its predicted impacts on reef flat habitat (0 to 5 m depth), shallow water coral habitats (5 to 30 m), deepwater coral habitat (30 to 70 m) and Sandy Islet, for three scenarios (worse case, intermediate case and best case).

Overall, the study concluded that minor seabed subsidence over the life of the Torosa reservoir affecting a part of Scott Reef and Sandy Islet would not significantly contribute to sea level changes and associated impacts. As such, no reduction in biological diversity or ecological integrity within the State Proposal Area is predicted to occur as a result of seabed subsidence. Subsidence will be monitored throughout the life of the Project as detailed in Section 6.3.20 of the draft EIS/ERD.

8.3.4.13 Unplanned marine discharges: hazardous and non-hazardous inorganic waste

A description and assessment of the potential impact on marine environmental quality from unplanned discharge of hazardous and non-hazardous inorganic wastes is presented in Section 8.2.4. This assessment concluded that in the unlikely event of an unplanned discharge, discharged materials in liquid or sludge form would be subject to rapid dispersion and dilution by prevailing currents, due to the open oceanic waters of the State Proposal Area. This would result in a temporary and highly localised change in water quality that would be highly unlikely to impact the deepwater benthic habitats of the State Proposal Area. Accidentally discharged non-buoyant waste would have the potential to sink to the seabed and impact epifauna, however, given the sparse nature of deepwater habitats that are well represented both in the State Proposal Area and regionally, any impacts are highly unlikely to reduce biodiversity or ecological integrity within the State Proposal Area.

Under normal operating conditions, drilling and vessel activity will be limited to the deep waters in proximity to the location of the proposed development wells and subsea infrastructure away from Scott Reef so any accidental discharge to the marine environment is highly unlikely to impact the Scott Reef benthic communities and habitats.

8.3.4.14 Physical presences (unplanned): invasive marine species (IMS)

Non-indigenous Marine Species (NIMS) are species which are translocated into a recipient environment where they are not historically found. Invasive marine species are NIMS that are translocated into a marine environment where they have the potential to establish and disrupt the natural balance of marine ecosystems.

Not all NIMS that are translocated to a receiving location will survive through to establishment and only a subset of these species that become established will impact on social/cultural, human health, economic and/or environmental values are considered IMS (Wells, 2018).

IMS can be introduced through a variety of natural and human mediated vectors. The key pathways for introduction of IMS to the State Proposal Area is within biofouling on external surfaces of vessels and within internal niche areas and systems, and through vessel's ballast water. The vectors for translocation are via project vessels and MODU(s).

A detailed assessment of the potential risks associated with unplanned introduction of IMS is provided in Section 6.3.21 of the draft EIS/ERD. This includes an overview of the potential pathways of introduction, the process of the establishment of an IMS, an assessment of project specific pathways of IMS introduction and potential impact to ecosystem dynamics that could occur as a result of the introduction and establishment of an IMS.

The majority of the State Proposal Area consists of deep offshore open waters, away from shallow habitats, that are not conducive to the settlement and establishment of IMS, due to the lack of benthic light (required to support the photosynthetic processes required for many NIMS) or suitable hard substrates to allow attachment and growth.

The primary receptors with respect to IMS in the State Proposal Area are shallow-water marine habitats, species and ecosystem function at Scott Reef. Shallow water marine habitats, such as coral reefs, are considered susceptible to the introduction and subsequent establishment of IMS due to the availability of light and complex habitats. IMS introduced to shallow water marine habitats are, therefore, much more likely to successfully establish than those introduced to deep oceanic waters.

Shallow water benthic habitats, such as coral reefs, are considered susceptible to the introduction and subsequent establishment of IMS due to the availability of light and available substrate for establishment. IMS introduced into shallow water marine habitats are, therefore, much more likely to successfully establish than those introduced to deep oceanic waters (i.e. the deepwater habitat of the reef system).

Sites subject to existing disturbance such as Scott Reef are also considered to be more susceptible to IMS. This includes artificial structures (e.g. the two shipwrecks at Scott Reef; **Section 5.4.3.2** of the draft EIS/ERD), sites effected by coral bleaching and/or extreme weather events (as described for Scott Reef in **Section 5.3.1.3** of the draft EIS/ERD), and those areas impacted by tourism or fishing (e.g. tourism and Indonesian fishers at Scott Reef). The cumulative pressure of these disturbances may lead to weakened ecosystem function and reduced resilience to external pressures such as IMS. An IMS surveillance program at Scott Reef is proposed to be undertaken, with a survey completed prior to the commencement of the proposed Browse to NWS Project activities in the State Proposal Area to verify baseline condition, and periodic surveys over the life of the proposed Browse to NWS Project.

As described in **Table 6-146** of the draft EIS/ERD, given this sensitivity and the regional significance of Scott Reef, the consequence of the introduction and successful establishment of an IMS has been determined to represent a consequence level of Major due to the potential for regionally significant impacts to high value habitat. However, given the legislative and Woodside management controls in place to prevent translocation and establishment of IMS in the Project Area it is considered that the likelihood that IMS would be introduced, establish a self-sustaining population and cause environmental impacts to sensitive ecological communities within the vicinity of Project Area, including the State Proposal Area (e.g. Scott Reef) is remote.

8.3.4.15 Unplanned hydrocarbon releases

A detailed assessment of the potential risks associated with unplanned hydrocarbon releases is provided in **Section 6.3.21** of the draft EIS/ERD. Quantitative hydrocarbon spill modelling of various worst-case hydrocarbon release scenarios is presented in **Section 6.3.21.3** of the draft EIS/ERD. This included modelling of a loss of well integrity scenario at the TRA-C well (Scenario 1) which represents the worst case impacts to Scott Reef. The summarised result of the modelling of Scenario 1 are presented in **Table 6-158** and **Figure 6-51** of the draft EIS/ERD.

Based on the outcomes of quantitative spill modelling, hydrocarbon spills resulting from the Proposal have the potential to significantly impact shallow benthic communities and habitats within the State Proposal Area. However, given existing legislative and management controls the occurrence of hydrocarbon spills is considered highly unlikely.

8.3.4.16 Cumulative impacts

Given the distance of the State Proposal Area from other operating developments in the region, it is not considered credible cumulative impacts from the proposed Browse to NWS Project (or the Proposal) and other developments will occur.

With respect to the Commonwealth waters component of the proposed Browse to NWS Project, other than potentially hydrotest discharges (discussed below), it is not expected that planned marine discharges to Commonwealth waters would contribute to cumulative impacts on benthic communities and habitats within the State Proposal Area. Operational discharges (i.e. produced water and cooling water) from the FPSO facilities (in Commonwealth waters) have been designed and will be managed to ensure the defined threshold values (e.g. 99% species protection or no effect concentrations) at the State waters boundary are met (95% of the time based on dispersion modelling results).

While not considered the base-case, the potential discharge of hydrotest fluids from the BTL at the Torosa pipeline end terminal (**Section 6.3.17** of the draft EIS/ERD), may result in a temporary reduction in water quality within the State Proposal Area and thus a potential impact on adjacent benthic communities and habitats. The modelling results (**Section 6.3.17.3** of the draft EIS/ERD) indicate this would be restricted to deep waters surrounding the pipeline end terminal (461 m depth) and therefore impacts would be restricted to a small proportion of sparsely distributed epifauna. Given this, and the fact this discharge would be a one-off event that would occur prior to the commencement of operations, the discharge of hydrotest fluid from the BTL at the Torosa pipeline end terminal would not be expected to contribute significantly to cumulative impacts to benthic communities and habitats within the State Proposal Area.

8.3.5 Assessment of Impacts

The assessment of the predicted impacts to benthic communities and habitats in the State Proposal Area (i.e. deepwater habitats and Scott Reef habitats) demonstrates predominately temporary and minor impacts to the deepwater habitats on a localised scale associated with some of the proposed activities. Such impacts are associated with the direct disturbance resulting from the installation of the subsea infrastructure and the discharge of drill cuttings and fluids during development drilling.

Given the proposed location of the wells and subsea infrastructure will be in deep waters (>300 m), away from Scott Reef and that under normal operating conditions the drilling and vessel activity will be limited to the immediate vicinity of the subsea infrastructure, it is considered unlikely that marine discharges will impact Scott Reef shallow water benthic communities and habitats (<75 m water depth). Given the potential sensitivities of Scott Reef benthic communities and habitats to sedimentation from surface drill cuttings discharges, Woodside has committed to managing the discharges of drill cuttings and fluids at TRA, TRD, TRE and TRF drill centre locations using established and proven techniques such that impacts to Scott Reef shallow water benthic communities and habitats (<75 m water depth) are avoided.

In summary, given the localised scale and temporary nature of potential impacts to deepwater benthic communities and habitats, and no predicted impact to Scott Reef benthic communities and habitats, there is not expected to be any reduction in diversity or ecological integrity within the State Proposal Area.

In addition, the localised and temporary nature of the predicted sediment deposition mean that no impacts to benthic communities and habitats associated with State marine parks (the closest being over 400 km from the State Proposal Area) are expected to occur.

Given the above, impacts to benthic communities and habitats within the State Proposal Area as a result of the proposed Browse to NWS Project (or the Proposal) are expected to be consistent with the EPA objective for the environmental factor – benthic communities and habitats.

8.3.6 Mitigation

Level of Ecological Protection

As described in **Section 8.2.6**, and EMQP will be prepared and implemented to achieve the proposed LEPs (**Figure 8-1** and **Figure 8-2**). With the implementation of the EMQP, it is expected a maximum LEP will be achieved in the majority of the State Proposal Area, including all Scott Reef shallow water benthic communities and habitats (<75 m water depth) during construction and operations. A high LEP will be achieved for the deep waters of the State Proposal Area where subsea infrastructure will be located, except where a moderate LEP is proposed within a 1000 m radius of each drill centre during construction and operations; and 500 m around subsea infrastructure during construction. Further, an area of moderate LEP is proposed during construction where the potential discharge of hydrotest fluid from the BTL (in Commonwealth waters), may incur into the State Proposal Area.

Specific proposed measures to mitigate and manage unavoidable impacts from planned activities and reduce the environmental risk associated with unplanned events and incidents are presented in **Chapter 6** of the draft EIS/ERD and these will be incorporated into the EQMP where relevant. Measures presented in the draft EIS/ERD will also be incorporated into activity specific Environment Plans to be submitted for acceptance by DMIRS prior to the activity commencing within the State Proposal Area.

Drilling discharge management

As detailed in **Section 8.2.4.8**, modelling indicated that the sea surface discharge of drill cuttings from the bottom-hole sections generated at the previously proposed TRE and TRD drill centre locations would potentially result in incursions of sediment plumes and associated increased sedimentation to portions of North and South Scott Reef including within the lagoons.

Given the potential sensitivities of Scott Reef shallow water benthic communities and habitats to sedimentation from drilling discharges, Woodside has committed to managing the drilling discharges (in particular bottom hole discharges) using established and proven techniques (e.g. disposal at alternative locations if necessary) at drill centre locations in the State Proposal Area (i.e. TRA, TRD, TRE and TRF) in such a manner that avoids impacts to Scott Reef shallow water benthic communities and habitats (<75 m water depth). This approach is outlined in **Section 8.2.6**.

8.3.7 Predicted Outcome

Cumulative loss assessment

WA EPA Technical Guidance - Protection of Benthic Communities and Habitats, requires the establishment of a local assessment units (LAUs) to establishes the spatial context for the calculation and assessment of recoverable impacts and cumulative losses (EPA, 2016c).

The following five LAU representing the broad benthic community and habitat types are proposed for the State Proposal Area.

- Scott Reef south lagoon deepwater coral habitats
- Scott Reef north deepwater sediment habitat
- Scott Reef south deepwater sediment habitat
- Scott Reef north shallow water benthic communities and habitats
- Scott Reef south shallow water benthic communities and habitats.

As per the EPA technical guidance *"Calculating cumulative losses relies on three fundamental pieces of information – 1) estimates of the areas of benthic communities and their habitats present before European habitation, 2) estimates of the extent of historic and approved losses, and 3) predictions of the additional losses associated with the current proposal (EPA, 2016c)."* In this regard:

- Original spatial extent is considered to be the entire spatial extent of the two above defined broad habitat types.
- No historical losses have been recorded. While Woodside has drilled seven previous wells within the State Proposed Area, impacts from the associated drill cuttings discharge are considered reversable (as described in Section 8.3.4.9), with benthic biota expected to have recolonised the area once drilling is completed.
- Proposed extent of permanent loss (0.31km^2) from proposal has been estimated based on the planned seabed disturbance for the installation of subsea infrastructure.
- Up to 3.84 km^2 of reversible loss may occur as a result of indirect impact from subsea infrastructure. Reversible loss is not included in the cumulative loss estimates.

Table 8-7 summarises the cumulative benthic communities and habitat loss estimates for the State waters around Scott Reef LAU.

Table 8-7 Cumulative permanent benthic communities and habitat loss assessment for State waters around Scott Reef LAU

Benthic communities and habitat type	Original spatial extent (pre-European habitation)	Historic and approved losses	Current % remaining	Proposed extent of permanent loss from proposal	Spatial extend of cumulative loss	% remaining after proposal
Scott Reef south lagoon deepwater coral habitats	213.47 km^2	0 km^2	100%	0 km^2	0 ha	100%
Scott Reef north deepwater sediment habitat	311.26 km^2	0 km^2	100%	0.31 km^2	0.31 km^2	99.90 %
Scott Reef south deepwater sediment habitat	379.16 km^2	0 km^2	100%	0 km^2	0 km^2	100%
Scott Reef north shallow water benthic communities and habitats	179.51 km^2	0 km^2	100%	0 km^2	0 km^2	100%
Scott Reef south shallow water benthic communities and habitats	147.14 km^2	0 km^2	100%	0 km^2	0 km^2	100%

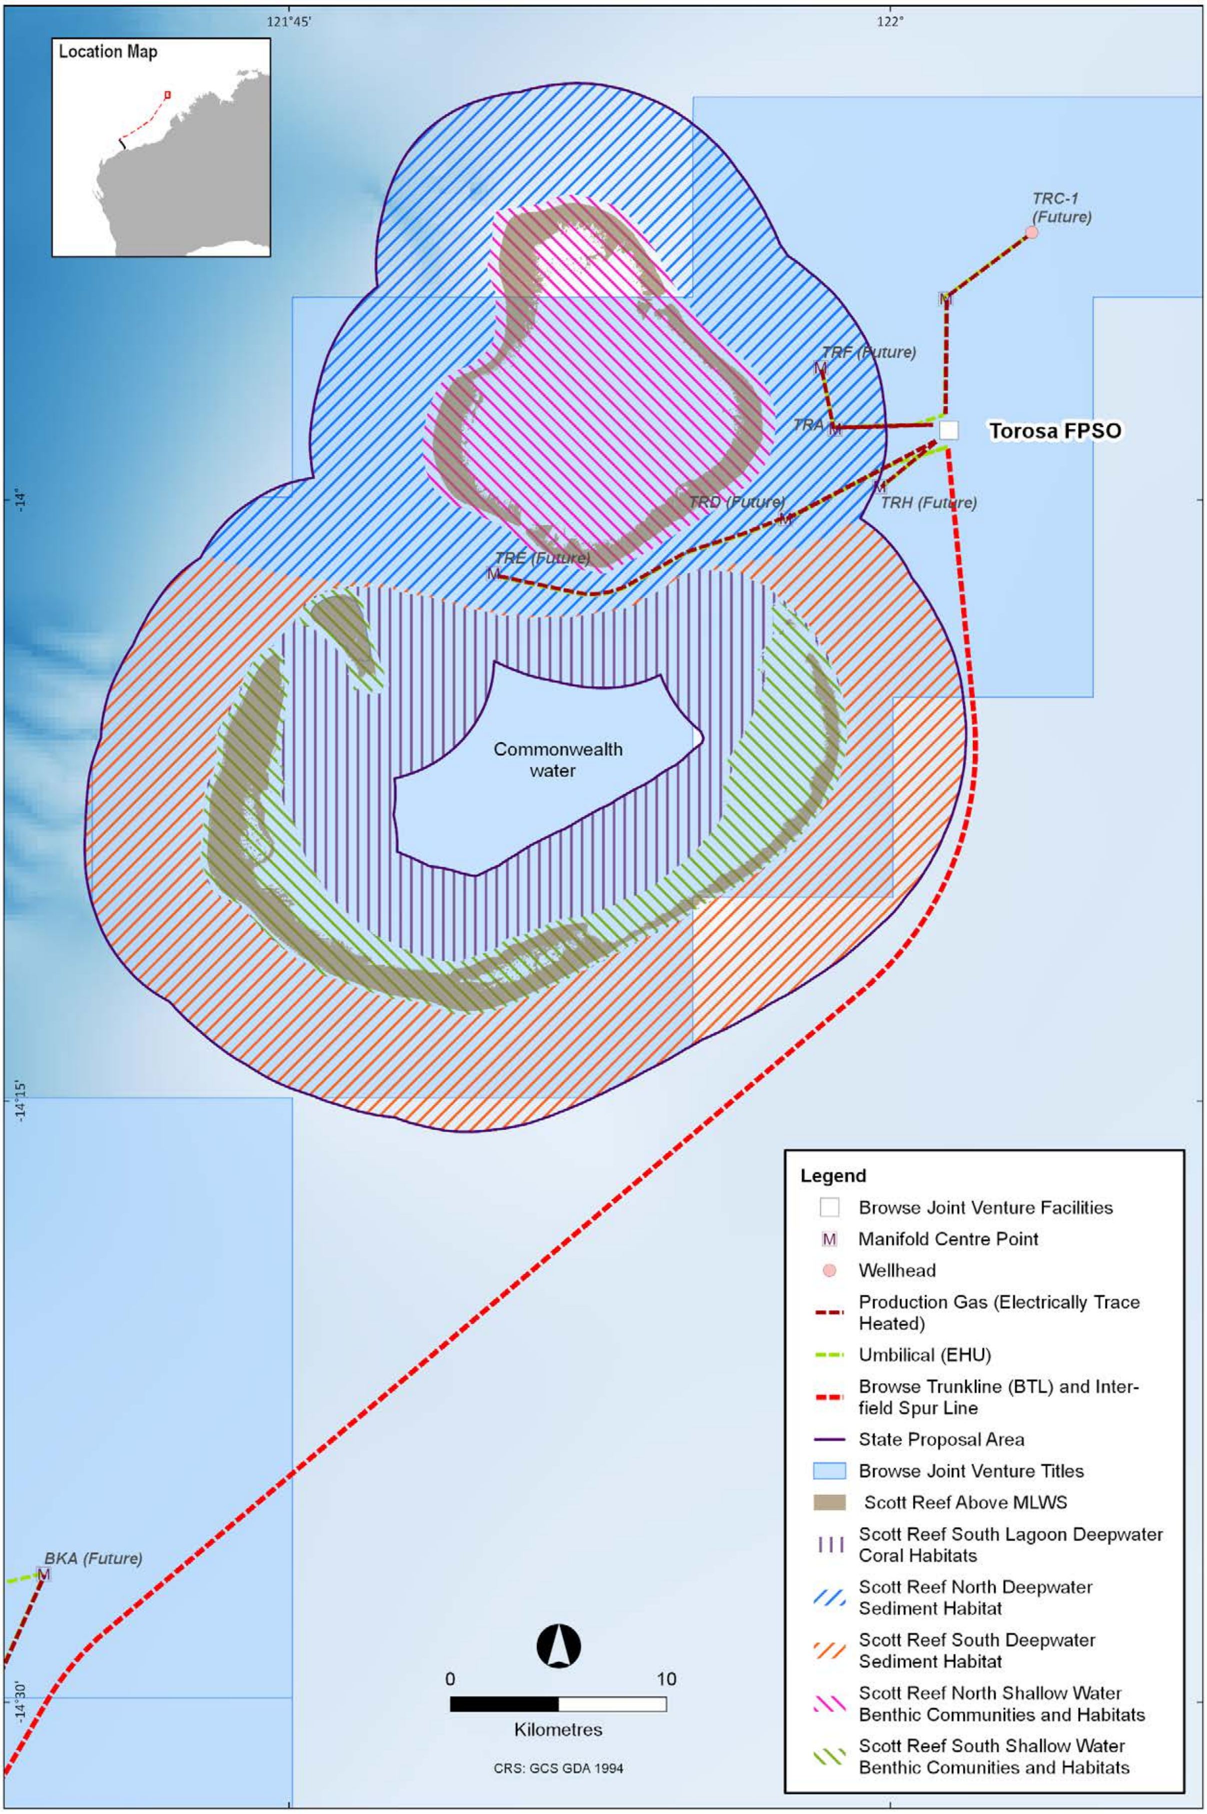

Figure 8-4 Proposed State Proposal Area Local Assessment Units

Summary

Impacts to benthic communities and habitats within the State Proposal Area have been reduced by locating the FPSO facilities, BTL and inter-field spur line outside of the State Proposal Area, and siting infrastructure within the State Proposal Area in deep waters off Scott Reef. This will result in any impacts being restricted to the deepwater benthic habitats, with no impacts to Scott Reef benthic communities or habitats.

Impacts will be further reduced by implementing mitigation and management measures, the majority of which are standard maritime and offshore oil and gas industry practice. However, given the potential sensitivities of Scott Reef shallow water benthic communities and habitats to sedimentation from drilling discharges, Woodside has committed to managing the drilling discharges (in particular bottom hole discharges) at drill centre locations in the State Proposal Area (i.e. TRA, TRD, TRE and TRF) in such a manner to avoid impacts to Scott Reef shallow water benthic communities and habitats (<75 m water depth) (refer to **Section 8.2.6**). Implementation of this management approach will be assured through activity specific Environment Plan(s) under Petroleum Legislation.

Given cumulative losses (historical plus proposed) of benthic communities and habitats will be limited to a small portion that are well represented both in the State Proposal Area and regionally (approximately 0.11% of Scott Reef north deepwater sediment habitat LAU with no losses in any of the other four proposed LUA), the Proposal is not predicted to result in any reduction of biological diversity and ecological integrity within the State Proposal Area.

As such, the WA EPA environmental objective *"to protect benthic communities and habitats so that biological diversity and ecological integrity are maintained"* will be achieved for the Proposal; and the predicted impacts on benthic communities and habitats within the State Proposal Area are considered **Acceptable**.

8.4 Key Environmental Factor – Marine Fauna

8.4.1 EPA Objective

The EPA objective for marine fauna is *"To protect marine fauna so that biological diversity and ecological integrity are maintained"* (EPA, 2016b).

8.4.2 Policy and Guidance

The following policy and guidance have been considered in relation to the EPA environmental factor - marine fauna:

EPA Policy and Guidance

+ Statement of Environmental Principles, Factors and Objectives (EPA, 2016b)
+ Environmental Factor Guideline – Marine Fauna (EPA, 2016b).

Other Policy and Guidance

+ *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act) Policy Statement 2.1 – Interaction between Offshore Seismic Exploration and Whales (Department of the Environment, Water, Heritage and the Arts, 2008)
+ Conservation Management Plan for the Blue Whale - A Recovery Plan under the EPBC Act (Commonwealth of Australia, 2015a)
+ Conservation advice *Anous tenuirostris melanops* Australian lesser noddy (Threatened Species Scientific Committee, 2015a)
+ Approved Conservation Advice for *Megaptera novaeangliae* (humpback whale) (Threatened Species Scientific Committee, 2015b)
+ Recovery plan for marine turtles in Australia (Commonwealth of Australia, 2017a)
+ Conservation advice *Rhincodon typus* whale shark (DEWHA, 2015c).

8.4.3 Receiving Environment

Marine fauna that may occur within the Browse Development Area are described in detail in **Chapter 5** of the draft EIS/ERD. Marine fauna that may occur in the State Proposal Area are summarised below, with cross references to specific sections of **Chapter 5** of the draft EIS/ERD provided for further detail.

Seabirds and migratory shorebirds

Seabirds birds have been observed in low numbers at Scott Reef, as described in **Section 5.3.2.4.1** of the draft EIS/ERD. Sandy Islet (the only permanently emergent land mass at Scott Reef) may be used by nesting seabirds and is known to provide roosting habitat for low numbers of individuals but it is not large enough to support large numbers of seabirds at any one time. Scott Reef is recognised as part of a resting Biologically Important Area (BIA) for the little tern (*Sternula albifrons*) (**Section 5.3.2.2** of the draft EIS/ERD). This species is widely distributed within Australia and is expected to occur within the State Proposal Area.

Migratory shorebirds may also use Scott Reef as a staging ground during migrations, for nesting and roosting and have occasionally been observed in very low numbers, as detailed in **Section 5.3.2.4.2** of the draft EIS/ERD.

Marine mammals

Marine mammals have wide distributions that are associated primarily with seasonal feeding and migration patterns that are linked to their reproductive cycles. A number of marine mammal species have been identified as potentially occurring within the wider Project Area, as described in **Section 5.3.2.5** of the draft EIS/ERD. A number of surveys have been undertaken in recent years to establish baseline data for marine mammals, primarily humpback whales and pygmy blue whales, within proximity of the Browse Development Area, including the State Proposal Area. These are summarised in **Section 5.3.2.5** of the draft EIS/ERD. The species discussed below are considered likely to occur within the State Proposal Area.

- Humpback whale - the humpback whale (*Megaptera novaengliae*) is listed under the EPBC Act as Vulnerable, Migratory and Marine, and as Conservation Dependant under the *Biodiversity Conservation Act* (BC Act). This species has a wide global distribution and displays migratory behaviours, as described in **Section 5.3.2.5.1** of the draft EIS/ERD. Recent studies have indicated that this species travels less than 46 km from the coastline and within waters less than 50 m deep (RPS Environment and Planning, 2010b; 2012). Sightings have, however, been recorded around Scott Reef. There are no known BIAs for this species within the State Proposal Area and only low numbers of humpback whales are expected to be present in the area.

  There are also key calving areas for the humpback whale between Broome and the northern end of Camden Sound, as described in **Section 5.3.2.5** of the draft EIS/ERD. Additionally, there is a migration BIA for the species (**Section 5.3.2.2** of the draft EIS/ERD) which encompasses State waters around Broome.

- Pygmy blue whale - the pygmy blue whale (*Balaenoptera musculus*) subspecies is listed under the EPBC Act as Endangered, Migratory and Marine, and as Endangered under the BC Act. As described in **Section 5.3.2.5.2** of the draft EIS/ERD, this migratory subspecies is widely distributed from Indonesia to the south west of Australian and east along the Great Australian Bight to the Bass Straight. Noise logger data and historic observations have recorded this species within the waters of and surrounding Scott Reef, including the channel between North and South Scott Reef (McCauley, 2011). A possible foraging area has been documented at Scott Reef (although individuals have not been directly observed feeding) and the reef is recognised as part of a foraging BIA for this species in the Conservation Management Plan for the Blue Whale (Commonwealth of Australia, 2015b) (**Section 5.3.2.2** of the draft EIS/ERD). Migration and distribution BIAs for this species also encompass the State Proposal Area (**Section 5.3.2.2** of the draft EIS/ERD). The distribution BIA for the pygmy blue whale also encompasses State waters at Broome.

  Given the historical observations (Blue Planet Marine, 2019) and noise logger data (McCauley, 2011), it is expected that pygmy blue whales will occur in low numbers within the Browse Development Area, particularly within and around the waters of Scott Reef. It is acknowledged that pygmy blue whales have been recorded in the channel between North and South Scott Reef and they may forage opportunistically in and around Scott Reef during their migration to and from recognised aggregation areas.

- Bryde's whale - the Bryde's whale (*Balaenoptera edeni*) is listed under the EPBC Act as Migratory. The species is not listed under the BC Act. As described in **Section 5.3.2.5** of the draft EIS/ERD, noise loggers were deployed in and around Scott Reef from 2006 to 2009 and this species was found to be present in low numbers throughout the year. Data indicated this species was typically present as individuals, with occasional calls from multiple whales.

  Bryde's whales are subsequently expected to occur in low numbers within the State Proposal Area.

- Spinner dolphin - the spinner dolphin (*Stenella longirostris*) is a listed Cetacean under the EPBC Act and Priority 4 under the BC Act. This species is known from both oceanic and coastal habitats and has been recorded near Scott Reef in 2008 and 2009, as described in **Section 5.3.2.5** of the draft EIS/ERD. This species is likely to be found in or within the vicinity of the State Proposal Area.

Marine turtles

Marine turtles may occur within the Project Area, as described in **Section 5.3.2.6** of the draft EIS/ERD. As marine turtles are highly migratory it is possible that all six marine turtle species may occur within the State Proposal Area. The green turtle (described in **Section 5.3.2.6** of the draft EIS/ERD) and hawksbill turtle (described in **Section 5.3.2.6** of the draft EIS/ERD) are considered most likely to occur within the State Proposal Area as these species are known to nest at Sandy Islet. Both species are listed as Vulnerable under the EP Act and the EPBC Act. The internesting, nesting and post-nesting migratory behaviour of the green turtle at Scott Reef and surrounds has been studied in some detail and is summarised in **Section 5.3.2.6** of the draft EIS/ERD.

There are nesting/internesting BIAs for the green and hawksbill turtle at Scott Reef (described in Section 5.3.2.2 of the draft EIS/ERD) due to nesting habitat on Sandy Islet. While green turtles are known to nest each season at this location in low numbers, only one hawksbill turtle has been recorded nesting at this location. Habitat Critical to the Survival of a Species has also been designated for the green turtle at Scott Reef (Section 5.3.2.3 of the draft EIS/ERD), in order to preserve the genetic stock of the nesting population associated with these locations.

Sea snakes

Comprehensive surveys of sea snakes were undertaken at Scott Reef in February, September and November of 2006. A number of sea snake species were identified as part of these surveys (listed in Section 5.3.2.7 of the draft EIS/ERD). Sea snakes were typically associated with complex reef habitats and survey results indicated that these individuals were likely residential to Scott Reef. Sea snakes are expected to occur within the State Proposal Area.

Fish

Demersal and pelagic fish communities and species that may occur within the Project Area are listed and described in Section 5.3.2.8 of the draft EIS/ERD. Surveys of shallow water fish communities were undertaken at Scott Reef in 2006. The overall composition of fish fauna at Scott Reef was found to be generally similar to oceanic reefs in the tropical Indo-west Pacific, with a stronger affinity to the islands of eastern Indonesia than to the adjacent Australian mainland. Studies were also undertaken using Baited Remoted Underwater Video Systems (BRUVs) in the deeper waters of South Scott Reef lagoon and found herbivorous and coral feeding species to be widespread.

Species of sharks and rays identified as potentially occurring within the Project Area include the whale shark, shortfin mako, longfin mako, green sawfish and largetooth sawfish. There are no BIAs or known important habitat for these species within the State Proposal Area. The whale shark is a widely distributed migratory species and may occur within the vicinity of Scott Reef whilst undertaking migratory movements. The shortfin and longfin mako are widely oceanic species and, subsequently may occur within the vicinity of the State Proposal Area. The green and largetooth sawfish are not considered likely to occur within the State Proposal Area as they exhibit a preference for/reliance on inshore, shallow, sandy/muddy bottomed and estuarine habitats.

8.4.4 Potential Impacts

8.4.4.1 Summary of identified impacts and risks

Table 8-8 summarises the sources of potential impact to marine fauna from the Proposal. Table 8-8 is followed by a detailed description of the potential direct, indirect and cumulative impacts. An assessment of the significance of these impacts on marine environmental quality and a conclusion on the acceptability of the impacts in relation to the EPA environmental objective is presented in Section 8.4.5.

Table 8-8 Sources of Potential Impact to Marine Fauna from the Proposal

Aspect	Proposal Phase[1]					Source (in State jurisdiction)
	Dr	I	C	O	De	
Planned (routine and non-routine activities)						
Physical presence: light emissions	✓	✓	✓	✓	✓	Project vessels, installation vessels and MODU operating in the State Proposal Area Intermittent flaring from the MODU
Physical presence: electromagnetic emissions				✓		Subsea infrastructure
Atmospheric emissions: offshore activities	✓	✓	✓	✓	✓	Power generation on project vessels and the MODU Intermittent flaring from the MODU Venting of gas from the MODU (during well kick)

Aspect	Proposal Phase[1]					Source (in State jurisdiction)
	Dr	I	C	O	De	
Atmospheric noise	✓	✓	✓	✓	✓	Project vessels, installation vessels and MODU operating in the State Proposal Area Intermittent flaring from the MODU Helicopters movements Piling for MODU mooring installation (if required)
Underwater noise	✓	✓	✓	✓	✓	Project vessels, installation vessels and MODU operating in the State Proposal Area VSP/DAS during well development Piling for MODU mooring installation (if required) Wellhead operation Seabed preparation Helicopter movements
Marine discharges: sewage and sullage	✓	✓	✓	✓	✓	Project vessels, installation vessels and MODU operating in the State Proposal Area
Marine discharges: treated utility water, chemical and deck drainage	✓	✓	✓	✓	✓	Project vessels, installation vessels and MODU operating in the State Proposal Area
Marine discharges: produced water	✓					MODU during well unloading activities
Marine discharges: cooling water	✓	✓	✓	✓	✓	Project vessels, installation vessels and MODU operating in the State Proposal Area
Marine discharges: drilling and completions discharges	✓					MODU during drilling activities
Marine discharges: subsea control fluids	✓	✓		✓	✓	Subsea infrastructure during operations BOP during drilling ROVs
Marine discharges: hydrotest fluid	✓	✓	✓	✓		Temporary production system on MODU Integrity testing of subsea infrastructure
Production Activities: Seabed Subsidence				✓		Extraction of reservoir fluids
Unplanned events and incidents						
Marine discharges: hazardous and non-hazardous waste inorganic waste	✓	✓	✓	✓	✓	Project vessels, installation vessels and MODU operating in the State Proposal Area
Physical Presence (unplanned): Vessel Interactions with Fauna	✓	✓	✓	✓	✓	Project vessels and installation vessels operating in the State Proposal Area
Physical Presences (unplanned): Invasive Marine Species	✓	✓	✓	✓	✓	Project vessels, installation vessels and MODU operating in the State Proposal Area
Unplanned hydrocarbon releases	✓	✓	✓	✓	✓	Project vessels, installation vessels and MODU operating the State Proposal Area Subsea infrastructure

8.4.4.2 Physical presence: light

Modelling

A detailed description of the planned light emissions and an assessment of the potential impacts associated with these emissions is provided in **Section 6.3.3** of the draft EIS/ERD.

Light emissions within the State Proposal Area will occur as a result of operational and navigational lighting on project vessels, installation vessels and the MODU; as well as intermittent flaring on the MODU during well unloading. Light emissions in the State Proposal Area will occur only during the construction phase, contingency drilling and completion activities and during infrequent IMR activities. There will be no regular sources of light emissions in the State Proposal Area during routine operations.

To further understand the effects of light emissions on sensitive receptors (particularly green turtles), a line of sight assessment and a light density (luminous flux density) modelling study were conducted as part of the approved Browse FLNG Development EIS developed in 2014. Although the MODU for drilling is yet to be confirmed and different MODUs are likely to be used throughout the Browse field life, light levels associated with drill rig lighting are expected to be comparable to that studied. It is considered that these studies adequately define the potential impacts from artificial light emissions associated with the proposed Browse to NWS Project. Given the similar nature of the Proposal and the previously considered Torosa Subsea Development, the modelling undertaken previously is considered appropriate to inform the impact assessment of the Proposal. The results of these studies are summarised in **Section 6.3.3.3** of the draft EIS/ERD.

Due to the proximity of the TRE drill centre to Scott Reef, it was predicted direct light emitted from a drill rig at this location would be visible to some extent from all areas of Scott Reef, including Sandy Islet (approximately 7 km distant) (**Figure 6-5** of the draft EIS/ERD). However, based on the light density modelling, the maximum predicted light density levels from a drill rig at TRE reaching Sandy Islet are lower than 0.01 Lux, which is comparable to light levels between a moonless clear night sky and a quarter moon.

Light emissions from project vessels were not included in the line of sight assessment and light density modelling due to the temporary and transient nature of vessel movements.

Seabirds and migratory shorebirds

As described in **Section 6.3.3** of the draft EIS/ERD, seabirds and migratory shorebirds at Scott Reef may be affected by light emissions from project vessels and the MODU operating in the State Proposal Area. It should be noted, however, that the area does not represent a significant aggregation, nesting or roosting area.

The exact mechanism for navigation of migratory birds is not clear, however, it is widely thought that they use a mixture of natural cues, including the earth's magnetic field, solar and celestial orientation and polarised light patterns to determine their migratory pathway (Weindler and Liepa, 1999; Wiltschko and Wiltschko, 2001). Therefore, there is a risk that artificial light sources along migratory pathways may alter natural patterns, specifically in the absence of terrestrial landmarks (i.e. within offshore).

Studies have demonstrated that light from offshore facilities may attract migrating birds, with species that migrate during the night more likely to be affected (Marquenie et al., 2008; Verheijen, 1985). Birds may either be attracted by the light source itself or indirectly as lighted structures in marine environments tend to attract marine life at all trophic levels, creating food sources and shelter for seabirds. In some cases, sources of artificial light may provide enhanced capability for seabirds to forage at night (Verheijen, 1985). Studies in the North Sea indicated that migratory birds may be attracted to lights on offshore platforms when travelling within a radius of 3 to 5 km from the light source. Outside this area their migratory paths were not likely to be affected (Marquenie et al., 2008).

Additionally, artificial lighting may interfere with a bird's internal magnetic compass. It is thought that migratory birds require light from the blue-green part of the spectrum for magnetic compass orientation (Muheim et al., 2002; Wiltschko and Wiltschko, 2001, 1995) whereas red light, the long-wavelength component of light, is more likely to disrupt magnetic compass orientation.

Light from the MODU is unlikely to attract a significant number of such seabirds or shorebirds as activities are proposed to be located a considerable distance from known key aggregation areas such as Ashmore Reef (230 km), Roebuck Bay (370 km) and Eighty Mile Beach (500 km). Given a relatively small number of transiting birds are expected to pass in the vicinity of the Proposal Area, behavioural effects such as disorientation and/or attraction are expected to be minor. Similarly, birds roosting at night on Sandy Islet are unlikely to be disturbed given the low level of artificial light (less than 0.01 Lux) that would be received at Sandy Islet from the MODU.

Red light (the long-wavelength component of light) is more likely to disrupt the magnetic compass orientation of migratory birds. The expected spectral signature of light emissions from the MODU is between 530 to 620 nm (based on measurements of the drill rig during drilling of the TS-1 pilot appraisal well), with the red part of the spectrum outside of these ranges. Therefore, it is not expected that bird species magnetic compass orientation will be disrupted.

Fish
As described in Section 6.3.3 of the draft EIS/ERD, the waters of the State Proposal Area host a rich diversity of fish species, including demersal and pelagic fish. The attraction of fish to artificial light is a well know phenomenon and is likely to be associated with the increased availability of planktonic prey on the surface at night (due to vertical migration of zooplankton) and the increased prey detection abilities provided by the light (Marchesan et al., 2005). The response of fish to artificial light has been shown to differ depending on species and changes in behaviour due to the light regime potentially pose an increased risk of predation through changes to natural night time distribution (Marchesan et al., 2005; Nightingale and Simenstad, 2001). Artificial light may also exclude nocturnal foragers/predators from an area, allowing diurnal species to benefit from increased access to resources. Credible impacts from light emissions from the MODU and project vessels associated with the Proposal are expected to be restricted to localised fish attraction.

The whale shark is the only threatened fish species that is likely to occur within the State Proposal Area, albeit infrequently and in low numbers (refer to Section 5.3.2.8 of the draft EIS/ERD). Impacts from light emissions are not documented for this species, although this has been identified as an area for further research within the latest conservation advice for this species (Threatened Species Scientific Committee, 2015c). Given the low numbers and infrequent nature of whale shark presence in the State Proposal Area, it is considered highly unlikely that adverse impacts will occur to the small number of individual whale sharks that may encounter elevated, localised light emissions around the MODU and vessels. Occasional and temporary behavioural changes such as utilising attractant aggregations of food sources (such as zooplankton) for opportunistic feeding is known to occur around offshore facilities and may occur for the proposed Browse to NWS Project.

Marine turtles
Specific behavioural response to artificial light emissions by marine turtles relates to altered nocturnal behaviours (as described by Witherington and Martin (1996) and include:

- disorientation: loss of orientation, being unable to maintain constant directional movement
- misorientation: orientation in the wrong direction, for hatchling marine turtles on the beach, travel in any direction other than the general vicinity of the ocean.

There are many variables that influence the range and severity of potential impacts of light emissions on the behaviour of marine turtles including:

- turtle vision
- life stage (adult and hatchling).

Exposure of marine turtles to artificial light can result in changes to their natural behaviour, in particular with regards to nesting (Commonwealth of Australia, 2019). Sandy Islet (nesting habitat) and a 20 km interesting buffer of the surrounding waters are recognised as habitat critical to the survival of green turtles for the Scott Reef-Browse Island genetic stock in the Recovery Plan for Australian Marine Turtles 2017-2027 (Commonwealth of Australia, 2017a) (Figure 5-29 of the draft EIS/ERD). In addition, a BIA exists for internesting green and hawksbill turtles around Sandy Islet (Commonwealth of Australia, 2017a). Green turtles predominately nest at Sandy Islet between November and February and internesting turtles have been observed to aggregate primarily in an area to the south west of Sandy Islet. Only one hawksbill turtle has been recorded nesting at Sandy Islet (Section 5.3.2.5.2 of the draft EIS/ERD).

The Recovery Plan for Marine Turtles in Australia (2017-2027) identifies light pollution as a moderate risk to the Scott Reef-Browse Island green turtle genetic stock and a high risk to the WA hawksbill turtle population (Commonwealth of Australia, 2017a). The long-term recovery objective for marine turtles is to minimise anthropogenic threats to allow for the conservation status of marine turtles to improve so that they can be removed from the EPBC Act threatened species list.

The National Light Pollution Guidelines for Wildlife Including Marine Turtles, Seabirds and Migratory Shorebirds (Commonwealth of Australia, 2019) further discuss impacts and management of artificial light in relation to marine turtles.

Female adult marine turtles spend most of their lives in open ocean environments, however, female turtles return to natal beaches to nest and lay eggs, predominantly at night. There is significant evidence that indicates artificial lighting on or near nesting beaches may disrupt adult female turtle nesting behaviour (Commonwealth of Australia, 2019; Salmon, 2005; Salmon et al., 1992). Artificial lighting may affect the location that turtles emerge on the beach, the success of nest construction, whether nesting is abandoned and even the seaward return of adults (Salmon, 2005 and Salmon et al., 1992). It was found that turtles deterred from typical nesting beaches due to artificial lighting re-emerged onto alternate beaches outside of their typical range at increasingly distant and inappropriate nesting locations (Witherington and Martin, 2000, 1996). The selection of suboptimal nesting habitat may contribute to a reduction in the success of egg deposition and hatchling production (Witherington and Martin, 2000). There is no indication whether, under natural conditions, the full moon affects rates of female adults landing on a beach to nest. Nor is there any information available in the published literature that suggests adult turtles are affected by light during foraging activity (Pendoley, 2000).

Hatchlings have a strong tendency to orient themselves to the brightest light source, which under natural conditions is the seaward horizon (in natural circumstances derived from the moon for most of the month) rather than the darker silhouetted landward horizon (Limpus, 2006). The light glow created by artificial lighting may, therefore, cause hatchlings to be attracted to this light source rather than to the water (Witherington and Martin, 2000, 1996). Hatchlings which are disoriented or mis-oriented by artificial lights often do not find the sea promptly, this may lead to predation or exhaustion. Once in the ocean, little is known of the extent to which hatchlings still use vision over wave direction and the earth's magnetic field for orientation (Lohmann, 1992). Hatchlings swimming out to sea from the beach, however, may be attracted to light emissions from offshore structures or vessels, making them more susceptible to predation or vessel strike after they enter the water (Thums et al., 2016). Wilson et al. (2018) found that light emissions disrupted the dispersal of hatchlings and hatchlings become disoriented in nearshore environments.

The wavelength at which adult and hatchling turtles can sense light is important in determining their corresponding attraction and sensitivity to light emissions. Studies suggest that marine turtles are most sensitive to short-wavelength light in the near-ultraviolet to yellow region of the visible spectrum, from approximately 340 to 700 nm (Witherington and Martin, 2000). Studies on hatchling orientation, relative to spectrally controlled light sources, indicate that although the wavelength at which hatchlings can sense light varies between species, all turtle species are more sensitive to light in the blue and ultraviolet (UV) end of the spectrum. The most disruptive wavelengths to hatchlings are in the 300 to 500 nm range (Witherington, 1997). Light spill effects are not known to vary for different turtle species, however, green turtles are known to be attracted to light of lower wavelengths (<600 nm), with a preference for blue light (400 – 450 nm). The light intensity measurements and modelling predictions accounted for the full wavelength spectrum detected by marine turtles (340 to 700 nm) (ERM and SKM, 2008).

Based on lighting data from the drill rig, approximately 60% of the total light wavelength transmission is within the sensitive wavelength range for turtle hatchlings (300 to 500 nm) (ERM, 2010), with most common artificial light sources, such as fluorescent, generating light within these wavelengths (Witherington and Martin, 2000; Witherington, 1997). Given light intensity attenuated to 0.1 Lux at distances of 1.2 km from the studied drilling rig, given the distance of the TRE drill centre location from Sandy Islet it is only in the nearfield light spill that may impact adult breeding turtles on the water.

Based on the measured attenuation of light density and wavelengths from a drill rig at Scott Reef (ERM and SKM, 2008) and the predicted light levels modelled (ERM and SKM, 2008; Jacobs and SKM, 2014), light levels expected are below detection levels or so low (0.1 Lux) that no disturbance to nesting behaviour of adult female marine turtles is predicted at Sandy Islet. It should also be noted that drilling at TRE (the closet light source to Sandy Islet) is a temporary activity, with the MODU only likely to be in that location during the development drilling activities. Flaring from the MODU is not predicted to lead to impacts given its temporary nature (will only occur during well unloading activities and be of 1-2 days duration per well)

Impact of light spill around MODU on marine turtles

Historical studies have reported that due to turtle hatchlings' vision being limited in water, other more dominant navigational cues take over (Amos, 2014; Lohmann and Lohmann, 1992) such as surface currents (Frick, 1976; Liew and Heng Chan, 1992; Okuyama et al., 2009; Salmon and Wyneken, 1987; Witherington, 1995). However, more recent studies (Limpus et al., 2003; Thums et al., 2016) have demonstrated that offshore lights have the ability to attract in-water dispersing hatchlings, causing them to linger around the light source at sea. Additionally, Whelan and Wyneken (2007) and Harewood and Horrocks (2008) reported that artificial lights onshore, can slow down hatchlings' in-water dispersal. Harewood and Horrocks (2008) also demonstrated in this study, that hatchling turtles released from dark beaches, were attracted by artificial lights from neighbouring beaches that were only visible after the hatchlings were a substantial distance from shore. Perhaps more importantly, this study reported that a number of the unsuccessful hatchlings (unsuccessful, meaning hatchlings which did not correctly orientate themselves in a seaward position from the beach) stayed within 10 m of shore and travelled parallel to the shoreline, orientating towards the lighted headlands. Harewood and Horrocks (2008) concluded that artificial lights may override the effects of wave cues in low wave energy environments.

Similarly, Truscott et al. (2017) reported that artificial light sources can attract hatchlings back to shore. More recently, Wilson et al. (2018) confirmed that in the presence of artificial light, surface currents had little effect on the bearing of hatchling swimming, with 88% of individuals' trajectories tracked, orientated towards the experimental artificial lighting. Additionally, this study showed that under ambient conditions, ocean currents affected the bearing of hatchlings as they left the shore; however, when light was present, this effect was diminished, showing that the turtles actively swam against currents in their attempts to move towards light. Hatchling behaviour onshore is not expected to be impacted given the distance of Sandy Islet to TRE and the islet's height above sea level (maximum on west side of 5 m). Hatchling emergence and sea entry were assessed for potential impact from MODU lighting. It was concluded that hatchlings being drawn to MODU lighting thereby increasing vulnerability to predation were considered unlikely, given the distance of Sandy Islet from all drill centre locations and short travel distance to water regardless of direction.

As surface currents within the Scott Reef channel are known to be strong (averaging approximately 0.5 knots with speeds up to and exceeding two knots), it is unlikely that hatchlings will have the ability to linger and come within the light spill area in the vicinity of a MODU operating in the channel as a result of the artificial light acting as an attractant.

Therefore, artificial lighting associated with the MODU and proposed facilities, may theoretically have the potential to override and disorientate natural hatchling cues, potentially attracting individuals towards the structure. However, the results from the line of sight assessment undertaken as part of the previously proposed FLNG Development concept (ERM, 2010; Jacobs and SKM, 2014), demonstrate that the maximum predicted direct light levels reaching Sandy Islet from a MODU at the TRE drill centre (approximately 7 km away, **Figure 6-5** of the draft EIS/ERD) are less than 0.1 Lux.

For context, the predicted light intensity at this level of light is comparable to the light level between a moonless clear night sky and a quarter moon. Therefore, this level of light is not expected to be of an intensity (and associated wavelength frequency) to alter hatchling behaviour (attraction or mis-orientation of hatchlings leaving nesting sites on Sandy Islet). In addition, spectral analysis of light emissions from a flare at Thevenard Island (Pendoley 2000) determined that this light source does not contain a high proportion of light wavelengths within the range that is most disruptive to turtle hatchlings (300 to 500 nm). Therefore, no adverse impacts to hatchlings from artificial light are anticipated, despite the fact that some studies have demonstrated the theoretical potential for misorientation to some individuals.

Adult turtles passing through the Project Area may temporarily alter their normal behaviour whilst attracted to the light spill from the offshore facilities. Light spill of at least 0.1 Lux (i.e. at least quarter moon light intensity levels) is likely to extend 1.2 km radially from the MODU. While the light spill area overlaps with the internesting habitat for green turtles, it is not anticipated that large number of individuals will be present within this area given the preference to internest to the southwest of Sandy Islet and, therefore, will not be subject to behavioural impacts.

In addition, given the wide migratory distribution of adult turtles outside of nesting season (i.e. several hundred kilometres) and their low-density presence within the Project Area, the zone of influence and subsequent attraction from direct lighting is expected to be relatively minor in comparison to their migratory area, resulting in only a temporary disruption to a small portion of the adult turtle population. In addition, due to the limited range of any lighting impacts, it is not deemed that the predicted lighting impacts will adversely affect habitat critical to the survival of green turtles and is, therefore, not inconsistent with the recovery objectives outlined within the Recovery Plan for Marine Turtles in Australia (2017-2027) (Commonwealth of Australia, 2017a).

8.4.4.3 Physical presence: electromagnetic emissions

EMF will be generated within the State Proposal Area as a result of active heating of the subsea flowlines and power cables. The use of active heating technology in the design of the subsea system minimises the volume of Mono-ethylene Glycol (MEG) required to prevent hydrate formation. Active heating occurs using electricity and will be used in the infield flowlines and risers carrying the reservoir fluids from the subsea manifolds to the FPSOs. Active heating will prevent blockages in the flowlines which can occur when fluids cool causing hydrates and waxes to solidify. Active heating is not expected to be required continuously. While the flowlines are producing, active heating is not required, instead only being turned on for hydrate management when the flowline is not producing after a short period. Active heating remains on until the flowline recommences production and warms up. The other source of EMF will be the subsea power cables that distribute power generated at the FPSO to subsea infrastructure.

Further details of the potential electromagnetic emissions resulting from the proposed Browse to NWS Project is provided in **Section 6.3.4** of the draft EIS/ERD.

Fish

It is well established that many organisms including elasmobranchs and some bony fish, can detect both natural and anthropogenic EMFs, which many species use for directional movement, foraging and migration. However, the mechanism or mechanisms by which animals can exploit these fields is not fully understood. Some species may sense magnetic fields directly through biogenic magnetite crystals that reorient as the animal moves to maintain alignment with geomagnetic field lines (e.g., (Kirschvink et al., 2001)). Alternatively, the movement of seawater through magnetic fields (e.g. via current or tidal flow) induces localized electric fields that, although small (0.05-0.5 uV/cm), may be detectable by certain species (Kalmijn, 1982).

A wide range of studies have quantified the effects of EMFs on the behaviour and physiology of fish species (Gill et al., 2005; Normandeau et al., 2011; Walker, 2001). EMF produced from anthropogenic sources within the range of detection by electroreceptors have the potential to impact these species through alteration of their behaviour (attraction or repulsion) or disorientation, leading to interference in migration and movement patterns (Gill et al., 2005; Gill and Taylor, 2005). As electric fields diminish in strength with increasing distance from the source, elasmobranchs are likely to be initially attracted to the electric field, but as the individual approaches and the electric field strength increases there will be a point where the animal will turn and swim away. Gill and Taylor (2005) observed the repulsion of elasmobranchs from electric fields >10 µV/cm (Gill and Taylor, 2005). Therefore, when considering the result of the modelling presented in the draft EIS/ERD it is likely that fish may be repulsed by the electric field from the DEH system within a least 75m of the source. However, such impacts are predicted to be behavioural only with no physical impacts likely as a result of the likely avoidance of the source (Walker, 2001).

Marine turtles

Marine turtles are able to detect magnetic fields and note electric fields; however, they do not appear to be as sensitive to magnetic fields as elasmobranchs (Courtillotl et al., 1997; Normandeau et al., 2011; Walker, 2001) and furthermore the potential for behavioural disturbance or displacement is considered low as they are unlikely to be in proximity to the sources of EMF given the depth of water (>400 m) that the subsea infrastructure will be installed in.

Marine mammals

Marine mammals have been observed to be affected to varying degrees by magnetic fields but not electric fields (Fisher and Slater, 2010). Whales and dolphins appear to rely on geomagnetic contours for navigation, and magnetic fields generated by cables may result in disorientation and disruption to navigation and therefore negatively affect migratory behaviour (Meißner et al., 2006). However, the magnetic field strength emitted from the active heating of the flowlines will be indistinguishable from the earth's field beyond 1 m from the source (Table 6-28 of the draft EIS/ERD). In addition, given the depth of water (>400 m) that the majority of the EMF will be in, the significance level is predicted to be slight as it is not anticipated that marine mammals will be in close enough proximity to the source to elicit any lasting effects.

Summary

In summary, EMF can be detected at various levels of sensitivity by a number of marine fauna, with some behaviour responses evident from studies outlined above. However, EMF associated with DEH of the flowlines and risers are predicted to attenuate rapidly from the source, with the magnetic field predicted to be below the earth's natural geomagnetic level within 1 m and the electric field predicted to dissipate to 46 µV/cm within 75 m (Table 6-28 of the draft EIS/ERD). Given the depth of water (>400 m) that the majority of the EMF will be in and the predicted attenuation distances of the electric and magnetic fields, impacts on marine fauna are not predicted to be significant. If marine fauna are temporarily within the area of influence of EMF, effects are expected to be limited to short-term behavioural impacts.

8.4.4.4 Atmospheric emissions: offshore activities

Potential impacts relating the EPA Environmental Factor – Air Quality are addressed in Section 8.5. This assessment concluded that given the low emissions levels it is not anticipated emissions from the Proposal will result in lasting adverse impacts to air quality in the State Proposal Area.

Atmospheric emissions can cause direct impacts to fauna if they are present in the immediate vicinity of significant releases. Birds, for example, have been shown to suffer respiratory distress and illness when subjected to extended duration exposure to air pollutants (Sanderfoot and Holloway, 2017). Given that no lasting adverse impacts to air quality are predicted, it is highly unlikely that seabirds or migratory shorebirds will be exposed to air pollutants for an extended duration of time. As such, adverse impacts to seabirds or migratory shorebirds as a result of atmospheric emission are not predicted.

8.4.4.5 Atmospheric noise

Atmospheric noise emissions are expected to be generated in the State Proposal Area as a result of helicopter flyover during crew transfer, MODU flaring, pile driving and the operation of project vessels and the MODU. Predicted atmospheric noise levels and potential impacts relating to the proposed Browse to NWS Project are described in Section 6.3.7 of the draft EIS/ERD, which concluded that potential impacts to marine fauna from atmospheric noise emissions are expected to be limited to temporary behavioural responses.

Potential behavioural impacts for fauna that are present on the surface during a helicopter flyover (either in State waters near Broome during crew transfer, or in the State Proposal Area near the MODU during crew transfer) may include temporary 'startle' responses (e.g. diving). Such responses typically occur at relatively short ranges (tens of metres) (Hazel et al., 2007) and behavioural impacts during a typical helicopter flight are highly unlikely due to the altitude and distance between the helicopter and the potential receptor.

Atmospheric noise emissions from flaring on the MODU during well unloading will be intermittent and short in duration and are not expected to result in impacts to fauna beyond avoidance behaviour of individual fauna near the MODU at the time of flaring.

Some atmospheric noise emissions will occur during pile driving (if pile driving is required for the MODU mooring during the construction phase) and from project vessels and the MODU (particularly while on DP). The atmospheric noise emissions associated with these sources are expected to be relatively minor and are not expected to result in impacts to fauna beyond avoidance behaviour of individual fauna.

Seabirds and migratory shorebirds

Seabirds and migratory shorebirds may be affected by atmospheric noise emissions from helicopters transiting between Broome Heliport and the Browse Development Area. In particular, bird species present around Roebuck Bay and Cable Beach (<1 km from the Broome Heliport) and roosting birds at Scott Reef may be affected. Anthropogenic disturbance is identified in the Wildlife Conservation Plan for Migratory Shorebirds as a threat to the conservation of migratory shorebirds (Commonwealth of Australia, 2015c).

Given the high visibility and noise levels associated with helicopter movements, bird species are expected to actively avoid interaction. Any disturbance from helicopters in transit will be of limited duration as they pass by.

Impacts to bird species in the area surrounding Broome are expected to be negligible as helicopters passing by bird aggregation areas will be at significant altitude.

Impacts to bird species at Scott Reef are also expected to be negligible given the area does not represent a significant aggregation, nesting or roosting area for seabirds and migratory shorebirds; and flight paths will actively avoid roosting areas (Sandy Islet).

Bird species along the remainder of the flight path are expected to occur in low numbers. Given the altitude the helicopters will be flying at, impacts are not considered credible.

Cetaceans, marine turtles and fish

Underwater noise monitoring by McCauley (2008) at Scott Reef during a drilling program in 2008 demonstrated that noise emissions from helicopters operating from the MODU were not detectable at a noise logger set 4.6 km away (McCauley, 2008). Given this, and the typical characteristics of helicopter flights from Broome Heliport to the Project Area (i.e. duration, frequency, altitude and air speed), the predicted environmental impact of helicopter generated atmospheric levels that may result in behavioural disturbance to cetaceans, marine turtles and fish is not expected to have any lasting effect.

8.4.4.6 Underwater noise

Key underwater noise emissions that may occur within the State Proposal Area may include pile driving for mooring of the MODU, the MODU on DP, VSP and DAS and the operation of the wellhead. Other noise sources such as vessel operation, helicopter movements and seabed preparation are expected to be minor in comparison and are not considered further here. A detailed assessment of the potential impacts to marine fauna resulting from underwater noise emissions relating to the proposed Browse to NWS Project is presented in Section 6.3.8 of the draft EIS/ERD.

Modelling

Underwater noise emissions in the State Proposal Area are likely to be greatest during drilling, installation and decommissioning phases when activities such as pile driving may be occurring and vessel activity within the State Proposal Area is at its highest. Nevertheless, given the overall scale of the Proposal and activity phasing, noise emissions during these phases are expected to be limited and of relatively short duration. The results of the underwater noise modelling undertaken for the proposed Browse to NWS Project, including simulated animal movement and exposure modelling, are presented in **Section 6.3.8.3** of the draft EIS/ERD. The representative modelling undertaken for activities represent the State Proposal Area include driven piling modelling, the MODU on DP, well VSP and wellhead noise modelling. Modelling for MODU piling noise was based on results for the larger FPSO anchor piles using the IHC S-600 hammer. These estimated ranges of potential impact are considered a representative analogue for potential pile driving for mooring of the MODU, due to the expected smaller diameter and reduced loading requirements of the MODU mooring piles.

Marine mammals

The assessment presented in **Section 6.3.8** of the draft EIS/ERD concluded that predicted underwater noise emissions associated with key activities within the State Proposal Area may result in localised avoidance and/or behavioural disturbance of marine mammals within the vicinity of the proposed activities. Humpback and pygmy blue whales are known to occur within the State Proposal Area during their annual migrations, however, studies indicate these species occur in relatively low numbers within the area.

Injury/Mortality

As discussed in **Section 6.3.8.3** of the draft EIS/ERD, acoustic modelling of piling activities at Torosa (which incorporates animal behaviour and exposure), indicates that with exclusion zones in place, exposures to sounds levels where permanent injury could occur for pygmy blue whales is reduced to zero. Modelling also indicates that for other activities including the MODU on DP, it is highly unlikely that marine mammals would be exposed to underwater noise levels where injury would occur and as such injury or mortality to marine fauna is not expected.

Behavioural impacts

Modelling of the FPSO anchor piling activities estimated that only 0.32 migrating individual pygmy blue whales and 0.43 foraging pygmy blue whale individuals would exposed to behavioural response per pile. These estimates are based on the larger FPSO piles and does not include industry standard pre-start observations or soft starts and, as such, the actual number of individuals for MODU piling is likely to be less. Impacts are expected to be limited to temporary avoidance behaviour for the duration of the piling.

Modelling indicates that behavioural impacts may result from the MODU DP to a distance of 10.5 km. As with the piling noise, these impacts are expected to be limited to temporary avoidance behaviour and would only occur during MODU activities (in the order of 75 days per well).

Noise levels predicted from well evaluation using VSP demonstrate that potential behaviour impacts may occur within 1.6-1.7 km from the well; however, these would be limited to a very short duration as this type of activity will only occur for up to 10 hours per well.

Underwater noise levels from subsea wellheads will likely fall below the 120 dB re 1 µPa (SPL) cetacean behavioural response threshold within approximately 500 m of the wellheads at the TRD and TRE drill centres and are not predicted to reach the top 100 m of the water column, even directly above the wellheads. Potential impacts to whales and other cetaceans from increased noise levels in the vicinity of the wellheads are therefore expected to be minor and highly localised and are not expected to deter passage through Scott Reef Channel.

Potential impacts to whales and other cetaceans from increased noise levels in the vicinity of the wellheads are, therefore, expected to be localised and are not expected to cause significant impact at a population level.

Given the above, impacts to marine mammals resulting from underwater noise emissions are expected to be limited to occasional temporary behavioural/avoidance impacts to a relatively low numbers of transient marine mammals expected to seasonally occur within the State Proposal Area.

Marine turtles

A detailed assessment of the potential impacts to marine turtles resulting from underwater noise emissions relating to the proposed Browse to NWS Project is presented in **Section 6.3.8** of the draft EIS/ERD.

The underwater noise and animal exposure modelling (**Section 6.3.8.3** of the draft EIS/ERD) shows when representative animal movement and behaviour for both migratory and internesting turtles is incorporated into the impact piling propagation model for piling at the Torosa location in the State Proposal Area, no individual turtles would be exposed to injury levels. Additionally, when incorporating representative migratory green turtle animal movement and behaviour, the 95th percentile exposure ranges to the recoverable auditory fatigue (TTS) threshold are approximately 1.65 km for the IHC S-600 hammer. It should be noted these results do not incorporate incorporated potential shutdowns and soft starts.

Further, the modelling shows for other key activities the turtle injury PTS threshold is either not reached, or only extends a distance in the order of 130 m. Given these results do not incorporate animal movement and behaviour is based on the assumption the marine turtle is stationary within this distance for a 24 hour period (which is highly unlikely to occur), it is considered highly unlikely marine turtles will be exposed to underwater noise levels above the PTS threshold as a result of activities associated with the Proposal.

Modelling also indicates that the recoverable TTS threshold for marine turtles extends in the order of 50 – 160 m for other modelled activities, including the MODU on DP and VSP. It should be noted again that these results do not incorporate animal movement and behaviour and based on the assumption the marine turtle is stationary within this distance for the duration of VSP or 24 hour period for continuous sources (which is highly unlikely to occur). Given this, the planned mitigation measures (including exclusion zones and shut downs), the small exposure area, the temporary nature of the piling activities and the likely avoidance behaviour of marine turtles, it is considered that these impacts will be limited to behavioural (avoidance) impacts and would not result in any lasting effect. Given the temporary nature of the piling and drilling activities, these behavioural impacts are not expected to result in any reduction in nesting success or long terms impacts to internesting or migrating marine turtles in the State Proposal Area.

Fish

The modelling indicates that for the most sensitive fish groups (fish with swim bladder involved in hearing) sounds levels from the piling activities could exceed mortality levels within 200-210 m of the noise source. For fish species, including sharks, sound levels exceeding the recoverable TTS threshold are predicted to within in the order of 9 km at Torosa, assuming fish are stationary and do not avoid the sound source. Given the mobility of fish species and the likely avoidance behaviour, it is considered unlikely that such an exposure would occur.

For the other modelled activities, including the MODU on DP and VSP activities, the modelling indicates that fish would not be exposed to sound levels that could cause permanent injury or mortality. Recoverable injury to some fish species could occur, but only if the animals were in very close proximity to the sound sources (within a planar distance of 60 m) for a 48-hour period. As discussed above, this is considered highly improbable. Temporary impairment due to TTS could occur at similar short distances if fish remain at the same point within the sound field for long periods of time (12 hours), which is also considered highly improbable.

As such, it is considered that any impacts to fish from underwater noise emissions will be limited to temporary avoidance behaviour.

Sea snakes

As discussed in **Section 6.3.8** of the draft EIS/ERD, there is limited information available on hearing in sea snakes, but they are known to be capable of detecting pressure changes (Mick Guinea pers. comm.). Due to this and the fact that quantifiable distances for assessing impacts from continuous sounds only exist for fish, fish have been used as a surrogate for this assessment. As discussed, any impacts to fish from underwater noise emissions will be limited to temporary avoidance behaviour.

8.4.4.7 Marine discharges: sewage and sullage

An assessment of the potential impact on marine environmental quality from the discharge of sewage and sullage from project vessels, installation vessels and the MODU is presented in **Section 8.2.4**. This assessment concluded that changes to the physical and chemical properties of the marine water will be temporary and highly localised (discharge diluted to 1% of its original concentration with 50 m). Given the relatively small volume of treated sewage and sullage to be discharged and the expected rapid dilution of the discharge, the temporary and highly localised changes to water quality are not expected to have any lasting impacts to marine fauna within the State Proposal Area.

8.4.4.8 Marine discharges: treated utility water, chemical and deck drainage

An assessment of the potential impact on marine environmental quality from the discharge of treated utility water, chemical and deck drainage from project vessels, installation vessels and the MODU is presented in **Section 8.2.4**. This assessment concluded that treated utility water, chemical and deck discharges would result in temporary change water quality in the immediate vicinity of the discharge. Marine fauna such as fish, marine mammals and marine turtles may come into contact with these discharges. However, the discharges are expected to be rapidly diluted in the prevailing currents. Given this, the small volume of any discharge and the short, intermittent nature of these discharges, any contact with the discharge with marine fauna would be of extremely short duration. As such, it is not considered credible that toxic affects to marine fauna will occur as a result of the discharge of treated utility water, chemical and deck drainage within the State Proposal Area.

8.4.4.9 Marine discharges: produced water

As detailed in **Section 8.2.4**, given the small percentage that the PW component makes of the overall discharge from the MODU during well unloading, this discharge is addressed as part of the assessment of discharges during drill cuttings and fluids.

8.4.4.10 Marine discharges: cooling water

An assessment of the potential impact on marine environmental quality from the discharge of cooling water from project vessels, installation vessels and the MODU is presented in **Section 8.2.4**. This assessment concluded that cooling water discharges would result in temporary changes in water quality in the immediate vicinity of the discharge. While marine fauna such as fish, marine mammals and marine turtles may come into contact with these discharges, given that the discharges will disperse rapidly close to the discharge point and that any contact with the discharge with marine fauna will be of extremely short duration, it is not considered credible that toxic affects to marine fauna will occur as a result of the discharge of cooling water within the State Proposal Area.

8.4.4.11 Marine discharges: drill cuttings and fluids

An assessment of the potential impact on marine environmental quality from the discharge of drill cuttings and fluids from the MODU during drilling activities is presented in **Section 8.2.4**. This assessment concluded that change in to water quality (through elevated TSS and the introduction of contaminants) would be temporary and localised with no subsequent impacts to biota predicted.

This reduction in water quality would be temporary (limited to the duration of the activity) and subject to rapid dispersion and dilution by prevailing currents, due to the open oceanic waters of the State Proposal Area. There is a large body of knowledge indicating a discharge of cuttings with adhered fluids dilutes rapidly. These studies found that that within 100 m of the discharge point, a drilling cuttings and fluid plume released at the surface diluted by a factor of at least 10,000, while J.M. Neff (2005) stated that, in well-mixed oceans waters (as is likely to be the case within the drilling area), drilling fluid was diluted by more than 100-fold within 10 m of the discharge. While marine fauna such as fish, marine mammals and marine turtles may come into contact with these discharges, given that the discharges will disperse rapidly close to the discharge point and that any contact with the discharge with mobile marine fauna will be of extremely short duration, it is not considered credible that toxic affects to marine fauna will occur as a result of changes in water quality resulting from the discharge of drilling cuttings and fluids within the State Proposal Area.

The assessment presented in **Section 8.2.4** also found that impacts to benthic biota from sedimentation (discharged drill cuttings and fluids depositing on the seabed) are expected to be confined to sessile biota, such as sediment burrowing infauna and epifauna, where present in or on the seabed in immediate proximity to the well location (in the order of 200 m from each well). Away from this immediate area, sedimentation over the course of the drilling program would be low, equating to a thin veneer of settled drill cuttings which would likely be naturally reworked into surficial sediment through processes such as bioturbation (US EPA (2002). Ecological impacts are not expected for mobile benthic fauna such as crabs and shrimps or pelagic and demersal fish, given their mobility (IOGP, 2016).

As detailed in **Section 8.2.4.8**, modelling indicated that the sea surface discharge of drill cuttings from the bottom-hole sections generated at the previously proposed TRE and TRD drill centre locations would potentially result in incursions of sediment plumes and associated increased sedimentation to portions of North and South Scott Reef including within the lagoons.

Given the potential sensitivities of Scott Reef shallow water benthic communities and habitats (and associated marine fauna) to sedimentation from drilling discharges, Woodside has committed to managing the drilling discharges (in particular bottom hole discharges) at drill centre locations in the State Proposal Area (i.e. TRA, TRD, TRE and TRF) in such a manner to avoid impacts to Scott Reef shallow water benthic communities and habitats (<75 m water depth). This approach is outlined in **Section 8.2.6**.

Given that impacts to marine fauna will be limited to highly localised smothering of biota associated the deepwater habitats that are well represented both in the State Proposal Area and regionally, is not predicted to result in any reduction of biological diversity and ecological integrity at local and regional scales will occur.

8.4.4.12 Marine discharges: subsea control fluids

An assessment of the potential impact on marine environmental quality from the discharge of subsea control fluids during operation of the subsea infrastructure is presented in **Section 8.2.4**. This assessment concluded that the intermittent discharge of small volumes of subsea control fluid may result in a temporary reduction in water quality (limited to the duration of the activity), restricted to deep water and subject to rapid dispersion and dilution by prevailing currents, due to the open oceanic waters of the State Proposal Area.

Given the volume of the discharges and the location (at the seabed in water depths exceeding 300 m), it is not considered credible that impacts to marine fauna will occur as a result of the discharge of subsea control fluids within the State Proposal Area.

8.4.4.13 Marine discharges: hydrotest fluid

A description and assessment of the potential impact on marine environmental quality from the discharge of hydrotest fluid during integrity testing of the subsea infrastructure and the temporary production system on the MODU is presented in **Section 8.2.4**. Modelling (**Section 6.3.17.3** of the draft EIS/ERD) indicates that the hydrotest plume would be expected to travel in close proximity to the seabed at depths greater than 300 m. As such, fauna exposed to the discharge plume would be limited to pelagic fish and benthic biota in the deep waters of the State Proposal Area. The assessment presented in **Section 8.2.4** concluded that given the low volume of hydrotest fluid to be discharged, the low toxicity of the fluid, and the water depth at which the discharge would occur, hydrotest discharges within the State Proposal Area are not expected to result in any lasting impacts to benthic biota.

Impacts to pelagic fish from the discharge of hydrotest fluid is expected to be highly localised. Highly motile fish and other marine fauna have the capacity to adapt their behaviour in response to changes in environmental conditions and can be expected to move away from the discharge if exposed. The depth of the plume will also limit the number of fish that may potentially be affected.

Given the above, it is not expected that hydrotest fluid discharge in the State Proposal Area will result in a reduction in biological diversity or ecological integrity.

8.4.4.14 Unplanned marine discharges: hazardous and non-hazardous waste inorganic waste

A description and assessment of the potential impact on marine environmental quality from unplanned discharge of hazardous and non-hazardous inorganic wastes is presented in **Section 8.2.4**. This assessment concluded that in the unlikely event of an unplanned discharge, discharged materials in liquid or sludge form would be subject to rapid dispersion and dilution by prevailing currents, due to the open oceanic waters of the State Proposal Area. This would result in a temporary and highly localised change in water quality. Given this, it is not considered credible marine fauna will be exposed to sufficient concentrations or durations of the discharge constituents to elicit a toxic response.

Accidentally discharged non-buoyant waste has the potential to sink to the seabed and impact epifauna, however, given the sparse nature of deepwater habitats that are well represented both in the State Proposal Area and regionally, any impacts are highly unlikely to reduce biodiversity or ecological integrity within the State Proposal Area.

8.4.4.15 Physical presence (unplanned): vessel interactions with fauna

Vessel movements during all phases of the Proposal have the potential to cause injury or mortality to marine fauna as a result of accidental collisions (**Section 6.3.18** of the draft EIS/ERD). These movements include within the State Proposal Area, and within State coastal waters near the potential logistics supply bases (for example, FCTVs transiting between Broome and the FPSO facilities).

The type and number of vessels in the Project Area (and transiting to and from the Project Area) at any one time, and the duration of presence, will differ depending on the project phase. Vessel presence is expected to be greatest for short term project phases (e.g. drilling and completions, subsea installation including BTL, and commissioning), with the longer-term operational phase requiring fewer vessels.

In addition, in the instance flowlines are installed as towed bundles up to 10 km in length, the movement of these towed bundles have the potential to result in accidental collisions due to their length and limitations in manoeuvrability. Although it is noted that there will be far fewer movements of towed bundles (when compared with traditional installation techniques such as pipelay vessels) which are only required during construction. Towed bundle movements will occur at a significantly slower speed than regular vessel movements.

Vessel speed has been demonstrated as a key factor in collisions with marine fauna (Commonwealth of Australia, 2017b; Laist et al., 2001). Large (>80 m), fast moving vessels pose the highest risk, collisions are difficult to avoid as the vessels are potentially not able to slow down or evade marine fauna upon sighting (Laist et al., 2001). All project vessels will not travel at speeds greater than 12 knots with the State Proposal Area, or 6 knots in the Scott Reef channel, which will reduce the risk of accidental collisions (Laist et al., 2001).

Fast Crew Transfer Vessel (FCTV)

Fast crew transfer vessels (FCTVs) may be used for crew transfer. These FCTVs are capable of travelling at 50 – 55 knots. It is anticipated that one transfer per day would occur during normal operations, with additional transfers during shut downs and major maintenance. FCTVs will not travel at speeds in excess of 12 knots in the State Proposal Area.

If a FCTV is utilised, Woodside would select a FCTV design which inherently minimises the risk of unplanned interaction with marine fauna. The vessel has no propeller, has a shallow draught (<1 m) and can rapidly slow down, for example reaching dead stop within approximately 150 m from a cruising speed of 30 knots.

Figure 6-46 of the draft EIS/ERD provides an indicative route from Broome to the Browse Development Area. Recognising that interactions are most likely to coincide with increased fauna presence particularly within BIAs, consideration has been given to control measures beyond standard practice to specifically manage the risk of vessel strike within sensitive areas at sensitive times. The Proposed Management Approach for the FCTV is outlined in detail in Section 6.3.18.2 of the draft EIS/ERD.

Fauna that are highly unlikely to co-occur with project vessels

Fish

As described in Section 6.3.18 of the draft EIS/ERD, in the context of unplanned vessel collisions with fauna, the type of fish most likely to be impacted are larger pelagic species, particularly large sharks. Whale sharks are at particular risk due to their slow swimming behaviour and propensity to spend significant portions of time at the surface. Studies have indicated that whale sharks spend approximately 25% of their time less than 2 m from the surface and greater than 40% in the upper 15 m of the water column (Gleiss et al., 2013; Wilson et al., 2006). Conservation advice for the whale shark (Threatened Species Scientific Committee, 2015f) identifies vessel strike from large vessels as a key threat. However, based on the available information, it is expected that while whale sharks may occur within the Project Area, they are likely to occur in low numbers and as vagrant individuals (Meekan and Radford, 2010; Wilson et al., 2006). Whale sharks are not expected to occur in State waters near the potential logistic base locations. As such, it is considered highly unlikely that a vessel strike on a whale shark will occur in these areas. Given this, and the proposed vessel speed restrictions, it is considered highly unlikely that a vessel strike on a whale shark will occur.

Other fish are thought to be generally less vulnerable to vessel strike due to size, natural flee responses and preferred habitat use. Smaller fish may be at risk of mortality through being caught in vessel thrusters during station keeping operations. However, the noise emissions generated by the operation of dynamic positioning thrusters will generally deter fish from the vicinity of these operations.

Marine mammals – cetaceans (other than humpback whales)

As described in Section 6.3.18 of the draft EIS/ERD, large whales are more vulnerable to vessel collisions, particularly those species whose behaviour includes extended surface ‘milling’ time (Laist et al., 2001) and which demonstrate a lack of avoidance behaviour to approaching vessels (Nowacek et al., 2004). Cetacean calves and juveniles also have a higher risk of impact (Stevick, 1999), possibly due to less frequent and shorter dives (Szabo and Duffus, 2008).

Pygmy blue whales demonstrate limited behavioural responses to avoiding vessel collisions, with some undertaking slow shallow dives; however, active flee responses from vessels have not been observed (McKenna et al., 2015). While it is acknowledged that pygmy blue whales are vulnerable to vessel collisions, they are not expected to occur in high densities within the State Proposal Area or within State waters along the route that vessels will traverse when transiting to and from the Project Area. It is noted that the Conservation Management Plan for the Blue Whale (Commonwealth of Australia, 2015a) documents a possible foraging area within the vicinity of the Scott Reef. The plan also recognises vessel disturbance as a key threat to blue whales.

However, while studies indicate that pygmy blue whales pass through the Scott Reef area and that this area represents a potential foraging area for the species (as outlined in Conservation Management Plan for the Blue Whale (Commonwealth of Australia, 2015c)), multiple surveys, have failed to observe significant numbers of individuals present or evidence of foraging.

Therefore, co-occurrence of project vessels with pygmy blue whales is considered to be highly unlikely.

With respect to the other large cetacean species that may occur in the State Proposal Area, neither the Bryde's whale, sei whale or fin whale are expected to occur in large numbers in the State Proposal Area or in the State waters along the route project vessels would take when transiting to and from the Project Area.

Although spinner dolphins are very agile in the water and often display positive behaviours to the presence of vessels (e.g. bow-riding), there are a significant numbers of recorded vessel collisions with dolphins across Australia (DoEE, 2017). However, it is likely that the majority of such occurrences occur within more confined coastal areas subject to high vessel-traffic, significantly increasing the chance of vessel collision. It is thought that the risk of collision within deeper offshore waters with less vessel traffic, is significantly reduced (DoEE, 2017).

Given the low likelihood of co-occurrence of vessels with these species and the proposed speed restrictions within sensitive areas at sensitive times (**Table 6-139** of the draft EIS/ERD), the likelihood of vessel interaction with these species resulting in injury or mortality to fauna is considered highly unlikely, with the subsequent risk rated as low.

Fauna that may co-occur with project vessels

Humpback whales

As described in **Section 6.3.18** of the draft EIS/ERD, considering the densities, distributions and migratory pathways of the key marine fauna within the Project Area, humpback whales are considered to be the main species at risk from vessel interactions related to the proposed project activities, and in particular the possible use of FCTVs to transfer personnel from Broome to the offshore facilities during operations. A comprehensive review of ship strikes on large whales by Jensen and Silber (2004) revealed that humpback whales were the second highest reported species struck (44 records).

During their annual migration, humpback whales occur in relatively high densities between the Project Area and the Western Australian coast, include State waters adjacent to the mainland, which represents a migratory BIA for the species (see **Section 5.3** of the draft EIS/ERD for a detailed discussion on humpback whale distribution). Project vessels including FCTVs will traverse this BIA during transit from logistic bases (in Broome and Dampier) and the Project Area (**Figure 6-46** of the draft EIS/ERD). The risk of collision is likely to be higher during the southern migration given the broader migratory corridor and the presence of cow and calf pairs travelling at slower speeds with a higher proportion of time spent at the surface (Bejder et al., 2019; Zoidis and Lomac-MacNair, 2017). Vessel disturbance and strike is identified as a threat to humpback whales within the Conservation advice *Megaptera novaeangliae*, Humpback Whale (Threatened Species Scientific Committee, 2015e).

Given this risk to high value fauna, Woodside has developed a mitigation measures to reduce the likelihood and severity of potential vessel collision with humpback whales. These measures have been developed in consideration of the National Strategy for Reducing Vessel Strike on Cetaceans and other Marine Megafauna (Commonwealth of Australia, 2017b).

While research into these potential methods to reduce the risk of vessel collisions is limited in the existing scientific literature, a key action of the National Strategy for Reducing Vessel Strike is to identify and adopt best-practice mitigation measures and emerging technologies and encourage the development of new mitigation measures. It is therefore considered emerging technologies may offer an equivalent reduction in risk to speed reductions and may in future eliminate the need for speed reductions in sensitive areas at sensitive times.

The proposed management approach (outlined in **Section 6.3.18** of the draft EIS/ERD) including engineering controls and speed restrictions, is considered sufficient to manage the risk of unplanned vessel interaction with humpback whales.

Dugongs

As described in **Section 5.3.2.5** of the draft EIS/ERD, dugongs are known to inhabit the coastal regions of the Dampier Peninsula, with high concentrations noted at Roebuck Bay adjacent to Broome (RPS, 2010). Dugongs typically spend the majority of their time submerged, surfacing on average every 1-4 minutes (Anderson and Birtles, 1978; (De longh et al., 1997; and Cox, 2002) and typically spending less than 5% of the time resting on the surface (Hodgson, 2004). Because of their size, dugongs are susceptible to injury or mortality resulting from interaction with vessels, particularly when they rise to the surface to breathe, rest or forage in shallow waters. One of the primary responses of dugongs to approaching vessels is to move towards deeper water (Hodgson, 2004).

Similarly, dugongs are susceptible to injury or mortality resulting from interaction with vessels, particularly when they rise to the surface to breathe, rest or forage in shallow coastal waters as opposed to deeper offshore waters.

The proposed management approach (outlined in **Section 6.3.18.2** of the draft EIS/ERD) including engineering controls and speed restrictions, is considered sufficient to manage the risk of unplanned vessel interaction with dugongs, particularly given the likely lower densities of individuals within the proposed FCTV route and the minimal overlap between the proposed route and dugong foraging BIA.

Turtles

Turtles that are known to occur in the North West Marine Region are described in **Section 5.3.2.6** of the draft EIS/ERD). The Recovery Plan for Marine Turtles in Australia (2017-2027) (Commonwealth of Australia, 2017a) recognises vessel strikes as a moderate threat to the Scott Reef – Browse Island green turtle genetic stock. It also defines the area around Scott Reef as habitat critical to the survival of green turtles, and the area around the Lacepede Islands as an important nesting location for green turtles and flatback turtles.

Turtles may be particularly vulnerable to vessel strike while surfacing to rest or breathe. However, it has been reported that turtles spend a comparatively limited amount of time (3–6%) at the surface, with dives lasting between 15 and 60 minutes in general (Milton and Lutz, 2003). Turtles have been observed to avoid approaching vessels by moving away from the vessel's track (Hazel et al., 2007). Hazel et al. (2007) suggest that this avoidance behaviour is based primarily on visual cues (although the authors acknowledge vessel noise is within range of turtle hearing), and the success of this behaviour in avoiding a vessel strike largely depends on the speed of the approaching vessel and the prevailing water clarity. It's also likely that the propagation characteristics of underwater noise, particularly in high-use areas, would make it difficult for turtles to determine the direction of an oncoming vessel to elicit an appropriate flee response (Hazel et al., 2007). In the event of a collision, a turtle's carapace provides a level of protection from serious injury, although the type and severity of the injuries would depend on the force of the collision and structure and size of the vessel.

Turtles generally aggregate in shallow coastal areas adjacent to nesting beaches or in areas where sufficient food is available. Therefore, vessel interactions with turtles will be primarily restricted to coastal areas and in proximity to offshore nesting beaches (e.g. Scott Reef) where vessel movements would be limited, significantly reducing the likelihood of vessel collision.

The proposed management approach (outlined in **Section 6.3.18** of the draft EIS/ERD), including engineering controls and speed restrictions, is sufficient to manage the risk of unplanned vessel interaction with marine turtles.

8.4.4.16 Production activities: seabed subsidence

A detailed description of the subsea subsidence that may manifest as a result of production activities and as an assessment of the potential impacts that may result is provided in **Section 6.3.20** of the draft EIS/ERD. This includes peer reviewed modelling (**Section 6.3.20.3** of the draft EIS/ERD) which estimated that the average vertical seafloor movement is a total of approximately 5.4 cm (range 2.6 – 8.9 cm) over 40 years based on modelling; this is equivalent to 0.06-0.22 cm/year.

AIMS, (2012) assessed the impact of net sea level rise (from subsidence and climate change induced sea level rise) and its predicted impacts on reef flat habitat (0 to 5 m depth), shallow water coral habitats (5 to 30 m), deepwater coral habitat (30 to 70 m) and Sandy Islet, for three scenarios (worse case, intermediate case and best case).

Overall the study concluded that minor seabed subsidence over the life of the Torosa reservoir affecting a part of Scott Reef and Sandy Islet is not predicted to significantly contribute to sea level changes and predicted associated impacts.

Seabed subsidence has the potential to impact marine fauna by reducing the available land which comprises Sandy Islet. A reduction in the area of Sandy Islet could impact marine turtles, which use the landform for nesting, by reducing available or suitable nesting locations, which could impact nesting success rates. Scott Reef and Sandy Islet have experienced considerable natural variability in sea level over different time scales. For example, the tidal regime at Scott Reef is semi-diurnal with a maximum daily range of approximately 4 m. Similarly, sea levels can temporarily vary by tens of centimetres in response to large-scale oceanographic and atmospheric processes, such as the passage of mesoscale ocean eddies and inverse barometer effects with the passing of cyclonic and anticyclonic pressure systems. During El Nino years, up to 20 to 30 cm increases in sea levels occurred from the eastern Pacific Ocean to the eastern Indian ocean. Satellite data (ToPEX/Poseidon) from 1992 to 2009 showed intra and inter-annual sea level variability in the vicinity of Scott Reef to be from 30 cm below to 40 cm above MSL (Cooper et al., 2010). Given the natural variability in sea level at Scott Reef described above, nesting turtles (primarily green turtles) demonstrate the ability to cope with variability in the sea level at Sandy Islet.

The AIMS (2012) study concluded that with worst-case net sea level rises there is potential for wave action at high tide to reduce the height of the islet. This could affect the stability of Sandy Islet due to erosional processes associated with increased wave height, and thus impact on the availability of turtle nesting habitat. These impacts would still occur in the absence of subsidence, albeit over a slightly longer time period, with the most important factor influencing the persistence of the islet being the frequency of Category five cyclones. The study concluded for the worst-case scenario, given the highly variable nature of sea level rise, cyclone occurrence and sediment dynamics, that it is not possible to reliably predict the timing or just how much earlier any major changes to Sandy Islet might occur. The AIMS (2012) study concluded impact to Sandy Islet from the intermediate and bestcase scenarios would be negligible.

Given the above, no change is predicted in terms of available turtle nesting locations or nesting success as a result of seabed subsidence.

Likewise, no material reduction in the land available for seabirds that may roost on Sandy Islet is expected.

8.4.4.17 Physical presences (unplanned): invasive marine species (IMS)

A detailed assessment of the potential risks associated with unplanned introduction of IMS is provided in **Section 6.3.17** of the draft EIS/ERD.

While the primary receptors with respect to IMS within the State Proposal Area are the benthic communities and habitats of the Scott Reef system (refer to **Section 8.3.4.14**), once an IMS is established, it has the potential to impact on native species diversity and abundance in a variety of ways which may result in changes to ecosystem dynamics. This can occur via competition for or reduction of natural resources, predation, changes to nutrient cycling processes, habitat change and the spread of disease.

As described in **Section 6.3.17** of the draft EIS/ERD, given the existing legislative and management controls in place to prevent translocation and establishment of IMS within State waters, it is considered that the likelihood of IMS being introduced, establish a self-sustaining population and subsequently cause environmental impacts to the ecological communities within Scott Reef is remote and, as such, biological diversity and ecological integrity will be maintained.

8.4.4.18 Unplanned hydrocarbon releases

A detailed assessment of the potential risks associated with unplanned hydrocarbon releases is provided in **Section 6.3.19** of the draft EIS/ERD. Quantitative hydrocarbon spill modelling of various worst-case hydrocarbon release scenarios is presented in **Section 6.3.21.3** of the draft EIS/ERD. This included modelling of a loss of well integrity scenario at the TRA-C well (Scenario 1) which represents the worst case impacts to Scott Reef. The results of the modelling of Scenario 1 are summarised in **Table 6-158** and **Figure 6-51** of the draft EIS/ERD.

Based on the outcomes of quantitative spill modelling, hydrocarbon spills resulting from the proposed Browse to NWS Project have the potential to significantly impact marine fauna within the State Proposal Area and other State waters in the region such as at Rowley Shoals and the Kimberly coastline. Potential impacts to marine fauna exposed to hydrocarbons are described in **Section 6.3.21** of the draft EIS/ERD. Given the existing legislative and management controls, the occurrence of hydrocarbon spills is considered highly unlikely.

8.4.4.19 Cumulative impacts

Given the distance of the State Proposal Area from other operating developments in the region, it is not considered credible that cumulative impacts from the proposed Browse to NWS Project and other development will occur.

Cumulative impacts to marine fauna from exposure to multiple aspects resulting from the proposed Browse to NWS Project (both State and Commonwealth Waters components) are discussed in **Section 9.2.2** of the draft EIS/ERD. The following provides an assessment of the potential cumulative impacts to marine fauna located in the State Proposal Area.

Seabirds and migratory shorebirds

Atmospheric noise from helicopters and flaring from the MODU, and light emissions from vessels and the MODU, may have slight and temporary behavioural impacts on seabirds and migratory shorebirds. The low magnitude of these light impacts and the infrequent nature of the noise emissions means that exposure to multiple impact sources is unlikely, with cumulative impact to seabirds and migratory shorebirds expected to be limited to slight and temporary behavioural changes.

Fish

With respect to the Commonwealth waters component of the proposed Browse to NWS Project, it is not expected that planned marine discharges to Commonwealth waters will contribute to impacts on marine fauna within the State Proposal Area (**Chapter 6** of the draft EIS/ERD). Operational discharges (i.e. PW and cooling water) from the FPSO will be managed in Commonwealth waters to ensure the defined threshold values (e.g. 99% species protection or no effect concentrations) at the State waters 3 nm boundary are met 95% of the time based on dispersion modelling results.

Operational discharges within the State Proposal Area from project vessels and the MODU (such as cooling water and PW) are predicted to rapidly disperse and dilute within the receiving environment and therefore impacts to fish, if any, will be limited to a localised area within the associated mixing zone. In addition, the relatively low toxicity of these discharges, and short exposure time, means that a toxic response by fish is considered unlikely.

Likewise, modelling has indicated impacts to fish (including whale sharks) from underwater noise emissions are expected to be limited to behavioural impacts.

Given no lasting impacts to fish from marine discharges are predicted and impacts from underwater noise emissions are expected to be limited to behavioural impacts, cumulative impacts on fish as a result of the Proposal are not expected.

Marine mammals
The primary source of potential impacts to marine mammals such as pygmy blue whales in the State Proposal Area is from underwater noise emissions during construction (e.g. piling, VSP and DAS, and MODU on DP) and operations (e.g. subsea infrastructure operations). As described in **Section 6.3.8** of the draft EIS/ERD, modelling has indicated that although no injury or mortality to cetaceans is predicted to occur, there is potential for some degree of behavioural disturbance to cetaceans as a result of underwater noise emissions resulting from activities in the State Proposal Area. Potential impacts to whales and other cetaceans from increased noise levels in the vicinity of the wellheads are expected to be limited to behavioural/avoidance impacts to a relatively low numbers of transient marine mammals expected to seasonally occur within the State Proposal Area which is not recognised as habitat key to any life cycle stage (breeding, calving) or marked aggregations for marine mammals.

No other aspect is predicted to have any lasting effect on marine mammals and, as such, cumulative impact from multiple aspects is not expected.

Marine reptiles
The primary sources of potential impacts to marine turtles are artificial light emissions from the MODU and underwater noise emissions resulting from potential pile driving activities, drilling and the MODU DP.

As described above, it is considered that these impacts can be managed to an acceptable level through the implementation of mitigation measures. Cumulative impacts may occur as a result of simultaneous exposure to these sources. For example, nesting turtles or hatchlings attracted by light emissions from the MODU would subsequently be exposed to noise emissions from the MODU (e.g. DP noise). These cumulative impacts would be limited to behavioural responses for a small number of adult marine turtles.

Cumulative impacts to marine turtles may also occur as a result of attraction resulting from light emissions and concurrent exposure to other temporary, higher intensity noise emissions such as pile driving and VSP noise emissions. However, with the implementation of a proposed 500 m shut down zone during pile driving and VSP operations, as well as pre-start up visual observations, soft starts, operational, and shut-down procedures; cumulative impacts resulting from light and noise emission from pilling and VSP operations are not expected to occur.

Cumulative impacts could also occur as a result of non-simultaneous exposure to light and noise emissions. For example, decreased nesting success as a result of behavioural impacts from noise emissions (i.e. females avoiding nesting habitat at Sandy Islet) combined with decreased hatchling survival rates due to disorientation from light emissions would have a combined impact on the overall population success of green turtles. However, as described above, light and noise emissions are not expected to significantly impact the breeding cycle of marine turtles at Sandy Islet (predominately green turtles) and given the temporary nature of pile driving activities and the MODU's presence at a single location, no cumulative impacts on the nesting success or hatchling survival rates are expected as a result of the Proposal.

Potential impacts may also potentially occur to sea snakes as a result of marine discharges and underwater noise emissions resulting from the proposed Browse to NWS Project. As described in **Section 8.2.4**, impacts to water quality will be temporary and localised and impacts to sea snakes from noise emissions are expected to be limited to slight behavioural/avoidance impacts. As such, no cumulative impacts to sea snakes from the Proposal are predicted.

8.4.5 Assessment of Impacts

With the implementation of management measures such as shut down zones during activities such as piling and VSP, impacts to marine fauna are predicted to be restricted to temporary and localised behavioural impacts to a small number of individual seabirds and migratory shorebird, cetaceans, fish and marine turtles, primarily resulting from underwater noise and light emissions. These emissions will potentially occur from piling activities, VSP, project vessels and the MODU operating in the State Proposal Area, primarily during the construction phase of the project. There is no proposed permanent vessel or facilities presence in the State Proposal Area.

These behavioural impacts are not expected to impact foraging or nesting success and are not expected to reduce biological diversity or ecological integrity.

There is a risk of injury or mortality to a small number of individual animals resulting from collision with project vessels, particularly FCTVs. As described above, however, an adaptive management strategy will be implemented to ensure the risk of vessel strike is not significantly increased above the risk presented by existing marine traffic.

8.4.6 Mitigation

Chapter 8 of the draft EIS/ERD presents the overarching HSE management approach Woodside will implement for the proposed Browse to NWS Project.

Specific proposed measures to mitigate and manage unavoidable impacts from planned activities and reduce the environmental risk associated with unplanned events and incidents are presented in **Chapter 6** of the draft EIS/ERD.

Note that the measures presented in this draft EIS/ERD will be incorporated into activity-specific Environment Plans to be submitted for acceptance by DMIRS prior to the activity commencing within the State Proposal Area.

8.4.7 Predicted Outcome

Taking proposed mitigation and management measures into account; and considering the limited scope and scale of the Proposal (with no permanent facility or vessel presence) and the overall phasing of Proposal development, impacts to marine fauna within the State Proposal Area as a result of the proposed Browse to NWS Project are expected to be limited to temporary behavioural impacts to a small number of individual fauna.

Potential impacts to marine fauna that use the shallow water and emergent habitats of Scott Reef will be reduced by locating the FPSO facilities, BTL and inter-field spur line outside of the State Proposal Area and siting infrastructure within the State Proposal Area in deep waters off Scott Reef. As the State Proposal Area is not known to provide significant aggregation areas for birds or marine mammals, any impacts associated with Proposal activities on fauna are likely to be limited to transient individuals. Similarly, given the small scale of Proposal activities in the State Proposal Area, the temporary nature of the surface activities (restricted to the construction phase and intermittent IMR activities) and the distance from nesting and internesting sites for marine turtles, only a small portion of the turtle nesting population could be temporarily disturbed with no adverse impact on nesting success or hatchling survival rates predicted.

Impacts will be further reduced via the implementation of mitigation and management measures, the majority of which are standard maritime and offshore oil and gas industry practice. Implementation of these mitigation and management measures to ensure impacts are acceptable and ALARP will be assured through activity specific Environment Plans under other regulatory processes.

As such, the WA EPA environmental objective *"To protect marine fauna so that biological diversity and ecological integrity are maintained"* will be achieved for the proposed Browse to NWS Project; and the predicted impacts on marine fauna within the State Proposal Area are considered **Acceptable**.

8.5 Key Environmental Factor – Air Quality

8.5.1 EPA Objective

The EPA objective for air quality is *"To maintain air quality and minimise emissions so that environmental values are protected"* (EPA, 2016e).

8.5.2 Policy and Guidance

The following policy and guidance have been considered in relation to the EPA environmental factor - air quality.

EPA Policy and Guidance

- Statement of Environmental Principles, Factors and Objectives (EPA, 2016b)
- Environmental Factor Guideline – Air Quality (EPA, 2016e).

The Western Australia Government released a GHG Emissions Policy for Major Projects on 28 August 2019. The Policy includes an aspirational target of net zero GHG emissions by 2050. The Minister for Environment will consider how the Policy relates to major proposals assessed under Part IV of the EP Act (Government of Western Australia, 2019).

Public consultation on the WA EPA's draft Environmental Factor Guideline and Technical Guidance relating specifically to GHG emissions closed on 2 September 2019.

8.5.2.1 Receiving Environment

Air quality within the State Proposal Area is described in detail in **Chapter 5** of the draft EIS/ERD. The State Proposal Area is located approximately 260 km the WA coastline and is thus remote from urban and/or industrial air pollutants. Given this, air quality at the State Proposal Area is expected to be of high quality. Air quality of the receiving environment in relation to the atmospheric emissions resulting from the third party processing of Browse gas are described within the ERD associated with the North West Shelf Project Extension Proposal (EPA 2186, EPBC 2018/8335).

8.5.3 Potential Impacts

Summary of identified impacts and risks

Table 8-9 summarises the sources of potential impact to air quality from the Proposal. **Table 8-9** is followed by a detailed description of the potential direct, indirect and cumulative impacts. An assessment of the significance of these impacts on air quality and a conclusion on the acceptability of the impacts in relation to the EPA environmental objective is presented in **Section 8.5.4**.

Table 8-9 Sources of Potential Impact to Air Quality from the Proposal

Aspect	Proposal Phase[1]					Source (in State jurisdiction)
	Dr	I	C	O	De	
Planned (routine and non-routine activities)						
Atmospheric emissions: offshore activities	✓	✓	✓	✓	✓	Power generation on project vessels and the MODU. Intermittent flaring from the MODU Venting of gas from the MODU (during well kick)
Atmospheric emissions: third party processing of Browse gas			✓	✓		Emissions anticipated to result from third party processing of Browse gas

1 Dr = Drilling; I = Installation; C = Commissioning; O = Operation; De = Decommissioning

Atmospheric emissions: offshore activities
Atmospheric emissions will occur from activities within the State Proposal Area. Sources will include the combustion of fuel for power generation, intermittent flaring from the MODU during drilling and completions and the venting of reservoir gas in the event of a well kick (where there is an influx of gas into the wellbore while drilling). These emissions will occur mainly during the construction phase, with emissions during operations limited to vessel emissions during infrequent IMR activities. Atmospheric emissions generated may include carbon monoxide (CO), oxides of nitrogen (NOx), sulphur dioxide (SO_2), particulate matter less than 10 microns (PM10), mercury and non-methane volatile organic compounds (VOCs), such as BTEX (benzene, toluene, ethylbenzene and xylenes).

A detailed description of the planned atmospheric emissions (non GHG) from the offshore activities associated with the proposed Browse to NWS Project is provided in Section 6.3.5 of the draft EIS/ERD, which concluded that no material impact to local air quality or sensitive receptors would occur. Given the majority of emissions from the proposed Browse to NWS Project will occur during operations from the FPSO facilities in Commonwealth waters, the emissions planned within the State Proposal Area represent a small portion of the planned emissions. As such, it can be concluded impacts to air quality and sensitive receptors from these emissions are likely to negligible.

GHG emissions expected to occur within State jurisdiction are described in Section 7.4.4 of the draft EIS/ERD. GHG emissions occurring within State jurisdiction associated with the proposed Browse to NWS Project relate to activities in the State Proposal Area associated with the Torosa field. Total installation emissions across the life of the proposed Browse to NWS Project occurring within the State Proposal Area are estimated to be ~0.4 MT CO2-e (total over field life).

Atmospheric emissions: third party processing of Browse gas
The assessment of any potential impacts on the national heritage values, including aboriginal heritage values, of the listed National Heritage Place on the Dampier Archipelago that may be associated with the onshore processing of the Browse gas by the NWS JV, is addressed within the ERD associated with the North West Shelf Project Extension Proposal (EPA 2186, EPBC 2018/8335).

As described in Section 7.4.4 of the draft EIS/ERD, downstream GHG emissions have been apportioned based on the proportion of NWS processing plant capacity that Browse gas utilises, relative to the GHG footprint currently approved for the facility as per Ministerial Statement 536. Table 7-5 in Section 7.4.4 of the draft EIS/ERD details the reservoir emissions estimated to occur in each jurisdiction under the range of expected export gas specification outcomes. This is dependent on the outcome of final commercial arrangements between the Browse JV and NWS JV.

8.5.4 Assessment of Impacts

Air quality
While a slight reduction in air quality on a local scale will occur for the duration of the activities, given the low emissions levels and the very low background levels of contaminants, it is not anticipated emissions from the Proposal will have a lasting impact on air quality within the State Proposal Area.

8.5.5 Mitigation

Chapter 8 of the draft EIS/ERD presents the overarching HSE management approach Woodside will implement for the proposed Browse to NWS Project. Specific proposed measures to mitigate and manage air quality impacts from planned activities and reduce the environmental risk associated with unplanned events and incidents are presented in Chapter 6 of the draft EIS/ERD. Note the measures presented in this draft EIS/ERD will be incorporated into activity-specific Environment Plans to be submitted for acceptance by DMIRS prior to the activity commencing within the State Proposal Area.

Specific measures to manage and mitigate GHG emissions are presented in Section 7.7 of the draft EIS/ERD. The proposed Browse to NWS Project has proposed a GHG Abatement Plan to continuously review mechanisms to mitigate and manage GHG emissions and compliance with NGER/SGM baseline requirements through use of offsets, at this stage anticipated to be in the form of Australian Carbon Credit Units (ACCUs).

8.5.6 Predicted Outcome

Given the low emissions levels and distance of the emissions sources from the nearest sensitive environmental receptors, it is not anticipated emissions from the Proposal will have an impact on any sensitive receptors. The Proposal is expected to result in a localised, temporary and negligible reduction in air quality in the immediate vicinity of the release point with overall contributions to the atmosphere not expected to be significant. No impact to the environmental values of the State Proposal Area are expected.

As such, the WA EPA environmental objective *"To maintain air quality and minimise emissions so that environmental values are protected"* will be achieved for the Proposal; and the predicted impacts on air quality within the State Proposal Area around Scott Reef are considered **Acceptable**.

9. OTHER ENVIRONMENTAL FACTORS OR MATTERS

No other environmental factors or matters against the environmental objectives/s have been identified in the ESD and/or during stakeholder engagement.

10. MATTERS OF NATIONAL ENVIRONMENTAL SIGNIFICANCE

As detailed in Section 2.9 of the draft EIS/ERD (and Section 5.1), the proposed Browse to NWS Project was referred to the DoEE under the EPBC Act in October 2018 and subsequently determined to be a controlled action. The following Matters of National Environmental Significance (MNES) were identified as controlled action provisions for the proposed Browse to NWS Project:

- National heritage values of a National Heritage Place
- Listed threatened species and communities
- Listed migratory species
- the Commonwealth marine area, the protected matter being the environment generally.

Chapter 5 of the draft EIS/ERD summarises the specific MNES/existing environmental values identified as relevant to the proposed Browse to NWS Project. Potential impacts to these MNES (e.g. atmospheric emissions, marine discharges), and an assessment of the level of significance of these impacts to MNES are detailed in Chapter 6 and Chapter 9 of the draft EIS/ERD respectively. Proposed mitigation and management of these impacts are outlined within the respective impact and risk assessment for each aspect in Chapter 6 of the draft EIS/ERD.

WA State Legislation and policy relevant to the MNES listed above are detailed in Section 2.11.4 and Section 2.11.5 of the draft EIS/ERD, including the EP Act and BC Act.

In the event impacts to MNES cannot be avoided or mitigated to an acceptable level, an environmental offset plan will be developed, as described in Chapter 8 of the draft EIS/ERD. This excludes GHG emissions offsets, which have been considered separately in Chapter 7 of the draft EIS/ERD.

11. HOLISTIC IMPACT ASSESSMENT

An assessment of the Proposal against the relevant WA EPA's Environmental Objectives (as determined by the WA EPA) is provided in **Section 9.5** of the draft EIS/ERD.

This section assesses holistically the potential impacts of the Proposal on the whole environment. In accordance with 'Instructions on how to prepare an environmental review document' (EPA, 2018a) this section describes the connections and interactions between the environmental factors relevant to the Proposal and discusses the predicted outcomes of the Proposal in relation to the environmental principles and the EPA's environmental objectives.

The receiving environment relevant to the Proposal is characterised by relatively pristine offshore environment, largely unaffected by anthropogenic sources and of high marine and air quality. The Proposal's activities have the potential to affect various elements of the environment (as defined by the EPA's environmental factors). Where the receiving environment of environmental factors overlaps, the draft EIS/ERD has considered the receiving environment from the perspective of each relevant environmental factor.

The air quality and marine fauna environmental factors overlap in relation to potential impacts to seabirds and migratory shorebirds. However, as described in **Section 8.4.4**, no lasting effect on seabirds and migratory shorebirds from air emissions is predicted.

Significant overlaps exist between the other relevant factors (marine environmental quality, benthic communities and habits; and marine fauna), where impacts to components of one or more of these factors would potentially impact the other factors. For example, changes to marine environmental quality (e.g. water quality reduction) would potentially impact benthic communities and habitats (e.g. Scott Reef corals) and marine fauna (e.g. green turtles). This is one of the primary drivers in the setting of a level of ecological protection (no detectable change from natural background) for all of Scott Reef (<75 m water depth) and a high level of ecological protection (99% species protection) for the majority of the remainder of the State Proposal Area during steady state operations.

As described in **Section 8.2.6**, it is expected a maximum LEP will be achieved in the majority of the State Proposal Area during construction and operations. A high LEP will be achieved for the deep waters of the State Proposal Area where subsea infrastructure will be located, except where a moderate LEP is proposed within a 1000 m radius of each drill centre during construction and operations; and 500 m around subsea infrastructure during construction. Further, an area of moderate LEP is proposed during construction where the potential discharge of hydrotest fluid from the BTL (in Commonwealth waters), may incur into the State Proposal Area. An EQMP will be prepared and implemented to achieve this outcome.

No disturbance to Scott Reef shallow water benthic communities and habitats (<75 m water depth) will occur, with impacts to benthic habitats limited to the disturbance of approximately 4.15 km^2 (0.31 km^2 permanent and 3.84 km^2 reversible loss) of deepwater habitats that are well represented both in the State Proposal Area and regionally. Feasible mitigation measures (e.g. discharge at depth and/or skip and ship) exist to achieve the stated objective of avoiding impact on Scott Reef coral habitat. Impacts to other fauna such as seabirds and migratory shorebird, fish, marine mammals and marine turtles from marine discharges, light emissions and noise emissions are expected to be restricted to temporary behavioral impacts such as avoidance or attraction.

As such, in consideration of the interconnection between these environmental factors, and the detailed environmental assessment undertaken in the draft EIS/ERD, it is expected the environmental values of the State Proposal Area including marine environmental quality, biological diversity and ecological integrity, and air quality will be maintained, and the Proposal is **Acceptable**.

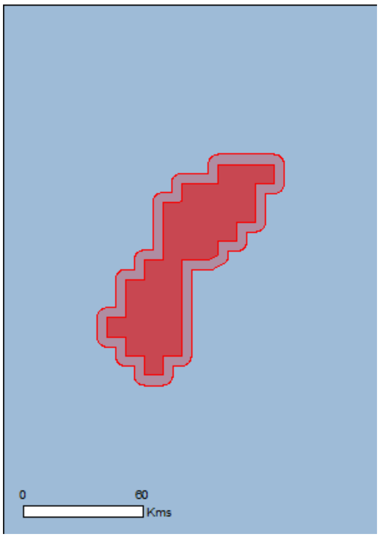
EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected.

Information on the coverage of this report and qualifications on data supporting this report are contained in the caveat at the end of the report.

Information is available about Environment Assessments and the EPBC Act including significance guidelines, forms and application process details.

Report created: 18/03/19 19:20:20



This map may contain data which are ©Commonwealth of Australia (Geoscience Australia), ©PSMA 2010

Coordinates
Buffer: 5.0Km

Summary

Matters of National Environmental Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	None
National Heritage Places:	None
Wetlands of International Importance:	None
Great Barrier Reef Marine Park:	None
Commonwealth Marine Area:	1
Listed Threatened Ecological Communities:	None
Listed Threatened Species:	19
Listed Migratory Species:	37

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at http://www.environment.gov.au/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Land:	None
Commonwealth Heritage Places:	1
Listed Marine Species:	67
Whales and Other Cetaceans:	25
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Australian Marine Parks:	None

Extra Information

This part of the report provides information that may also be relevant to the area you have nominated.

State and Territory Reserves:	None
Regional Forest Agreements:	None
Invasive Species:	None
Nationally Important Wetlands:	None
Key Ecological Features (Marine)	2

Details

Matters of National Environmental Significance

Commonwealth Marine Area [Resource Information]

Approval is required for a proposed activity that is located within the Commonwealth Marine Area which has, will have, or is likely to have a significant impact on the environment. Approval may be required for a proposed action taken outside the Commonwealth Marine Area but which has, may have or is likely to have a significant impact on the environment in the Commonwealth Marine Area. Generally the Commonwealth Marine Area stretches from three nautical miles to two hundred nautical miles from the coast.

Name
EEZ and Territorial Sea

Marine Regions [Resource Information]

If you are planning to undertake action in an area in or close to the Commonwealth Marine Area, and a marine bioregional plan has been prepared for the Commonwealth Marine Area in that area, the marine bioregional plan may inform your decision as to whether to refer your proposed action under the EPBC Act.

Name
North-west

Listed Threatened Species [Resource Information]

Name	Status	Type of Presence
Birds		
Anous tenuirostris melanops Australian Lesser Noddy [26000]	Vulnerable	Species or species habitat may occur within area
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat may occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area
Papasula abbotti Abbott's Booby [59297]	Endangered	Species or species habitat may occur within area
Mammals		
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Migration route known to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat likely to occur

Name	Status	Type of Presence within area
Reptiles		
Aipysurus apraefrontalis Short-nosed Seasnake [1115]	Critically Endangered	Species or species habitat likely to occur within area
Caretta caretta Loggerhead Turtle [1763]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Eretmochelys imbricata Hawksbill Turtle [1766]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Lepidochelys olivacea Olive Ridley Turtle, Pacific Ridley Turtle [1767]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Natator depressus Flatback Turtle [59257]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Sharks		
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat may occur within area
Glyphis garricki Northern River Shark, New Guinea River Shark [82454]	Endangered	Species or species habitat may occur within area
Rhincodon typus Whale Shark [66680]	Vulnerable	Species or species habitat may occur within area

Listed Migratory Species [Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Migratory Marine Birds		
Anous stolidus Common Noddy [825]		Species or species habitat likely to occur within area
Calonectris leucomelas Streaked Shearwater [1077]		Species or species habitat known to occur within area
Fregata ariel Lesser Frigatebird, Least Frigatebird [1012]		Species or species habitat known to occur within area
Fregata minor Great Frigatebird, Greater Frigatebird [1013]		Species or species habitat may occur within area
Sternula albifrons Little Tern [82849]		Congregation or aggregation known to occur within area
Migratory Marine Species		
Anoxypristis cuspidata Narrow Sawfish, Knifetooth Sawfish [68448]		Species or species habitat may occur within

Name	Threatened	Type of Presence
		area
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera edeni Bryde's Whale [35]		Species or species habitat likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Migration route known to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat may occur within area
Caretta caretta Loggerhead Turtle [1763]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Eretmochelys imbricata Hawksbill Turtle [1766]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Isurus oxyrinchus Shortfin Mako, Mako Shark [79073]		Species or species habitat likely to occur within area
Isurus paucus Longfin Mako [82947]		Species or species habitat likely to occur within area
Lepidochelys olivacea Olive Ridley Turtle, Pacific Ridley Turtle [1767]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Manta alfredi Reef Manta Ray, Coastal Manta Ray, Inshore Manta Ray, Prince Alfred's Ray, Resident Manta Ray [84994]		Species or species habitat known to occur within area
Manta birostris Giant Manta Ray, Chevron Manta Ray, Pacific Manta Ray, Pelagic Manta Ray, Oceanic Manta Ray [84995]		Species or species habitat likely to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat likely to occur within area
Natator depressus Flatback Turtle [59257]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Orcaella heinsohni Australian Snubfin Dolphin [81322]		Species or species habitat may occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
Physeter macrocephalus Sperm Whale [59]		Species or species habitat may occur within area
Rhincodon typus Whale Shark [66680]	Vulnerable	Species or species habitat may occur within area
Tursiops aduncus (Arafura/Timor Sea populations) Spotted Bottlenose Dolphin (Arafura/Timor Sea populations) [78900]		Species or species habitat may occur within area
Migratory Terrestrial Species		
Cecropis daurica Red-rumped Swallow [80610]		Species or species habitat may occur within area
Hirundo rustica Barn Swallow [662]		Species or species habitat known to occur within area
Motacilla cinerea Grey Wagtail [642]		Species or species habitat may occur within area
Motacilla flava Yellow Wagtail [644]		Species or species habitat may occur within area
Migratory Wetlands Species		
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat known to occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]		Species or species habitat may occur within area
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat may occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat may occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area

Fish		
Bhanotia fasciolata Corrugated Pipefish, Barbed Pipefish [66188]		Species or species habitat may occur within area
Campichthys tricarinatus Three-keel Pipefish [66192]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
Choeroichthys brachysoma Pacific Short-bodied Pipefish, Short-bodied Pipefish [66194]		Species or species habitat may occur within area
Choeroichthys suillus Pig-snouted Pipefish [66198]		Species or species habitat may occur within area
Corythoichthys amplexus Fijian Banded Pipefish, Brown-banded Pipefish [66199]		Species or species habitat may occur within area
Corythoichthys flavofasciatus Reticulate Pipefish, Yellow-banded Pipefish, Network Pipefish [66200]		Species or species habitat may occur within area
Corythoichthys intestinalis Australian Messmate Pipefish, Banded Pipefish [66202]		Species or species habitat may occur within area
Corythoichthys schultzi Schultz's Pipefish [66205]		Species or species habitat may occur within area
Cosmocampus banneri Roughridge Pipefish [66206]		Species or species habitat may occur within area
Doryrhamphus dactyliophorus Banded Pipefish, Ringed Pipefish [66210]		Species or species habitat may occur within area
Doryrhamphus excisus Bluestripe Pipefish, Indian Blue-stripe Pipefish, Pacific Blue-stripe Pipefish [66211]		Species or species habitat may occur within area
Doryrhamphus janssi Cleaner Pipefish, Janss' Pipefish [66212]		Species or species habitat may occur within area
Filicampus tigris Tiger Pipefish [66217]		Species or species habitat may occur within area
Halicampus brocki Brock's Pipefish [66219]		Species or species habitat may occur within area
Halicampus dunckeri Red-hair Pipefish, Duncker's Pipefish [66220]		Species or species habitat may occur within area
Halicampus grayi Mud Pipefish, Gray's Pipefish [66221]		Species or species habitat may occur within area
Halicampus spinirostris Spiny-snout Pipefish [66225]		Species or species habitat may occur within area
Haliichthys taeniophorus Ribboned Pipehorse, Ribboned Seadragon [66226]		Species or species habitat may occur within area
Hippichthys penicillus Beady Pipefish, Steep-nosed Pipefish [66231]		Species or species habitat may occur within area
Hippocampus histrix Spiny Seahorse, Thorny Seahorse [66236]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
Hippocampus kuda Spotted Seahorse, Yellow Seahorse [66237]		Species or species habitat may occur within area
Hippocampus planifrons Flat-face Seahorse [66238]		Species or species habitat may occur within area
Hippocampus spinosissimus Hedgehog Seahorse [66239]		Species or species habitat may occur within area
Micrognathus micronotopterus Tidepool Pipefish [66255]		Species or species habitat may occur within area
Solegnathus hardwickii Pallid Pipehorse, Hardwick's Pipehorse [66272]		Species or species habitat may occur within area
Solegnathus lettiensis Gunther's Pipehorse, Indonesian Pipefish [66273]		Species or species habitat may occur within area
Solenostomus cyanopterus Robust Ghostpipefish, Blue-finned Ghost Pipefish, [66183]		Species or species habitat may occur within area
Syngnathoides biaculeatus Double-end Pipehorse, Double-ended Pipehorse, Alligator Pipefish [66279]		Species or species habitat may occur within area
Trachyrhamphus bicoarctatus Bentstick Pipefish, Bend Stick Pipefish, Short-tailed Pipefish [66280]		Species or species habitat may occur within area
Trachyrhamphus longirostris Straightstick Pipefish, Long-nosed Pipefish, Straight Stick Pipefish [66281]		Species or species habitat may occur within area
Reptiles		
Acalyptophis peronii Horned Seasnake [1114]		Species or species habitat may occur within area
Aipysurus apraefrontalis Short-nosed Seasnake [1115]	Critically Endangered	Species or species habitat likely to occur within area
Aipysurus duboisii Dubois' Seasnake [1116]		Species or species habitat may occur within area
Aipysurus fuscus Dusky Seasnake [1119]		Species or species habitat known to occur within area
Aipysurus laevis Olive Seasnake [1120]		Species or species habitat may occur within area
Astrotia stokesii Stokes' Seasnake [1122]		Species or species habitat may occur within area
Caretta caretta Loggerhead Turtle [1763]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Foraging, feeding or related behaviour known to occur within area

Name	Threatened	Type of Presence
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Disteira kingii Spectacled Seasnake [1123]		Species or species habitat may occur within area
Disteira major Olive-headed Seasnake [1124]		Species or species habitat may occur within area
Emydocephalus annulatus Turtle-headed Seasnake [1125]		Species or species habitat may occur within area
Eretmochelys imbricata Hawksbill Turtle [1766]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Hydrophis coggeri Slender-necked Seasnake [25925]		Species or species habitat may occur within area
Hydrophis elegans Elegant Seasnake [1104]		Species or species habitat may occur within area
Hydrophis ornatus Spotted Seasnake, Ornate Reef Seasnake [1111]		Species or species habitat may occur within area
Lapemis hardwickii Spine-bellied Seasnake [1113]		Species or species habitat may occur within area
Lepidochelys olivacea Olive Ridley Turtle, Pacific Ridley Turtle [1767]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Natator depressus Flatback Turtle [59257]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Pelamis platurus Yellow-bellied Seasnake [1091]		Species or species habitat may occur within area

Whales and other Cetaceans [Resource Information]

Name	Status	Type of Presence
Mammals		
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera edeni Bryde's Whale [35]		Species or species habitat likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Migration route known to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Delphinus delphis Common Dophin, Short-beaked Common Dolphin [60]		Species or species habitat may occur within area
Feresa attenuata Pygmy Killer Whale [61]		Species or species

Name	Status	Type of Presence
		habitat may occur within area
Globicephala macrorhynchus Short-finned Pilot Whale [62]		Species or species habitat may occur within area
Grampus griseus Risso's Dolphin, Grampus [64]		Species or species habitat may occur within area
Kogia breviceps Pygmy Sperm Whale [57]		Species or species habitat may occur within area
Kogia simus Dwarf Sperm Whale [58]		Species or species habitat may occur within area
Lagenodelphis hosei Fraser's Dolphin, Sarawak Dolphin [41]		Species or species habitat may occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat likely to occur within area
Mesoplodon densirostris Blainville's Beaked Whale, Dense-beaked Whale [74]		Species or species habitat may occur within area
Orcaella brevirostris Irrawaddy Dolphin [45]		Species or species habitat may occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat may occur within area
Peponocephala electra Melon-headed Whale [47]		Species or species habitat may occur within area
Physeter macrocephalus Sperm Whale [59]		Species or species habitat may occur within area
Pseudorca crassidens False Killer Whale [48]		Species or species habitat likely to occur within area
Stenella attenuata Spotted Dolphin, Pantropical Spotted Dolphin [51]		Species or species habitat may occur within area
Stenella coeruleoalba Striped Dolphin, Euphrosyne Dolphin [52]		Species or species habitat may occur within area
Stenella longirostris Long-snouted Spinner Dolphin [29]		Species or species habitat may occur within area
Steno bredanensis Rough-toothed Dolphin [30]		Species or species habitat may occur within area
Tursiops aduncus (Arafura/Timor Sea populations) Spotted Bottlenose Dolphin (Arafura/Timor Sea populations) [78900]		Species or species habitat may occur within area
Tursiops truncatus s. str. Bottlenose Dolphin [68417]		Species or species habitat may occur within

Extra Information

Key Ecological Features (Marine)

[Resource Information]

Key Ecological Features are the parts of the marine ecosystem that are considered to be important for the biodiversity or ecosystem functioning and integrity of the Commonwealth Marine Area.

Name	Region
Continental Slope Demersal Fish Communities	North-west
Seringapatam Reef and Commonwealth waters in	North-west

Caveat

The information presented in this report has been provided by a range of data sources as acknowledged at the end of the report.

This report is designed to assist in identifying the locations of places which may be relevant in determining obligations under the Environment Protection and Biodiversity Conservation Act 1999. It holds mapped locations of World and National Heritage properties, Wetlands of International and National Importance, Commonwealth and State/Territory reserves, listed threatened, migratory and marine species and listed threatened ecological communities. Mapping of Commonwealth land is not complete at this stage. Maps have been collated from a range of sources at various resolutions.

Not all species listed under the EPBC Act have been mapped (see below) and therefore a report is a general guide only. Where available data supports mapping, the type of presence that can be determined from the data is indicated in general terms. People using this information in making a referral may need to consider the qualifications below and may need to seek and consider other information sources.

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Threatened, migratory and marine species distributions have been derived through a variety of methods. Where distributions are well known and if time permits, maps are derived using either thematic spatial data (i.e. vegetation, soils, geology, elevation, aspect, terrain, etc) together with point locations and described habitat; or environmental modelling (MAXENT or BIOCLIM habitat modelling) using point locations and environmental data layers.

Where very little information is available for species or large number of maps are required in a short time-frame, maps are derived either from 0.04 or 0.02 decimal degree cells; by an automated process using polygon capture techniques (static two kilometre grid cells, alpha-hull and convex hull); or captured manually or by using topographic features (national park boundaries, islands, etc). In the early stages of the distribution mapping process (1999-early 2000s) distributions were defined by degree blocks, 100K or 250K map sheets to rapidly create distribution maps. More reliable distribution mapping methods are used to update these distributions as time permits.

Only selected species covered by the following provisions of the EPBC Act have been mapped:

- migratory and
- marine

The following species and ecological communities have not been mapped and do not appear in reports produced from this database:

- threatened species listed as extinct or considered as vagrants
- some species and ecological communities that have only recently been listed
- some terrestrial species that overfly the Commonwealth marine area
- migratory species that are very widespread, vagrant, or only occur in small numbers

The following groups have been mapped, but may not cover the complete distribution of the species:

- non-threatened seabirds which have only been mapped for recorded breeding sites
- seals which have only been mapped for breeding sites near the Australian continent

Such breeding sites may be important for the protection of the Commonwealth Marine environment.

EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected.

Information on the coverage of this report and qualifications on data supporting this report are contained in the caveat at the end of the report.

Information is available about Environment Assessments and the EPBC Act including significance guidelines, forms and application process details.

Report created: 18/03/19 18:57:07

This map may contain data which are ©Commonwealth of Australia (Geoscience Australia), ©PSMA 2010

Coordinates
Buffer: 5.0Km

Summary

Matters of National Environmental Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	None
National Heritage Places:	None
Wetlands of International Importance:	None
Great Barrier Reef Marine Park:	None
Commonwealth Marine Area:	1
Listed Threatened Ecological Communities:	None
Listed Threatened Species:	20
Listed Migratory Species:	38

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at http://www.environment.gov.au/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Land:	None
Commonwealth Heritage Places:	None
Listed Marine Species:	73
Whales and Other Cetaceans:	25
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Australian Marine Parks:	3

Extra Information

This part of the report provides information that may also be relevant to the area you have nominated.

State and Territory Reserves:	None
Regional Forest Agreements:	None
Invasive Species:	None
Nationally Important Wetlands:	None
Key Ecological Features (Marine)	4

Details

Matters of National Environmental Significance

Commonwealth Marine Area [Resource Information]

Approval is required for a proposed activity that is located within the Commonwealth Marine Area which has, will have, or is likely to have a significant impact on the environment. Approval may be required for a proposed action taken outside the Commonwealth Marine Area but which has, may have or is likely to have a significant impact on the environment in the Commonwealth Marine Area. Generally the Commonwealth Marine Area stretches from three nautical miles to two hundred nautical miles from the coast.

Name
EEZ and Territorial Sea

Marine Regions [Resource Information]

If you are planning to undertake action in an area in or close to the Commonwealth Marine Area, and a marine bioregional plan has been prepared for the Commonwealth Marine Area in that area, the marine bioregional plan may inform your decision as to whether to refer your proposed action under the EPBC Act.

Name
North-west

Listed Threatened Species [Resource Information]

Name	Status	Type of Presence
Birds		
Anous tenuirostris melanops Australian Lesser Noddy [26000]	Vulnerable	Species or species habitat may occur within area
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat may occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area
Papasula abbotti Abbott's Booby [59297]	Endangered	Species or species habitat may occur within area
Mammals		
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Migration route known to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur

Name	Status	Type of Presence
		within area
Reptiles		
Aipysurus apraefrontalis Short-nosed Seasnake [1115]	Critically Endangered	Species or species habitat likely to occur within area
Caretta caretta Loggerhead Turtle [1763]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Eretmochelys imbricata Hawksbill Turtle [1766]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Lepidochelys olivacea Olive Ridley Turtle, Pacific Ridley Turtle [1767]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Natator depressus Flatback Turtle [59257]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Sharks		
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat may occur within area
Glyphis garricki Northern River Shark, New Guinea River Shark [82454]	Endangered	Species or species habitat may occur within area
Pristis zijsron Green Sawfish, Dindagubba, Narrowsnout Sawfish [68442]	Vulnerable	Species or species habitat known to occur within area
Rhincodon typus Whale Shark [66680]	Vulnerable	Foraging, feeding or related behaviour known to occur within area

Listed Migratory Species [Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Migratory Marine Birds		
Anous stolidus Common Noddy [825]		Species or species habitat likely to occur within area
Calonectris leucomelas Streaked Shearwater [1077]		Species or species habitat known to occur within area
Fregata ariel Lesser Frigatebird, Least Frigatebird [1012]		Species or species habitat likely to occur within area
Fregata minor Great Frigatebird, Greater Frigatebird [1013]		Species or species habitat may occur within area
Phaethon lepturus White-tailed Tropicbird [1014]		Foraging, feeding or related behaviour likely to occur within area

Name	Threatened	Type of Presence
Sternula albifrons Little Tern [82849]		Congregation or aggregation known to occur within area
Migratory Marine Species		
Anoxypristis cuspidata Narrow Sawfish, Knifetooth Sawfish [68448]		Species or species habitat known to occur within area
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera edeni Bryde's Whale [35]		Species or species habitat likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Migration route known to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat may occur within area
Caretta caretta Loggerhead Turtle [1763]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Eretmochelys imbricata Hawksbill Turtle [1766]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Isurus oxyrinchus Shortfin Mako, Mako Shark [79073]		Species or species habitat likely to occur within area
Isurus paucus Longfin Mako [82947]		Species or species habitat likely to occur within area
Lepidochelys olivacea Olive Ridley Turtle, Pacific Ridley Turtle [1767]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Manta alfredi Reef Manta Ray, Coastal Manta Ray, Inshore Manta Ray, Prince Alfred's Ray, Resident Manta Ray [84994]		Species or species habitat known to occur within area
Manta birostris Giant Manta Ray, Chevron Manta Ray, Pacific Manta Ray, Pelagic Manta Ray, Oceanic Manta Ray [84995]		Species or species habitat likely to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Natator depressus Flatback Turtle [59257]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area

Name	Threatened	Type of Presence
Orcinus orca Killer Whale, Orca [46]		Species or species habitat may occur within area
Physeter macrocephalus Sperm Whale [59]		Species or species habitat may occur within area
Pristis zijsron Green Sawfish, Dindagubba, Narrowsnout Sawfish [68442]	Vulnerable	Species or species habitat known to occur within area
Rhincodon typus Whale Shark [66680]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Tursiops aduncus (Arafura/Timor Sea populations) Spotted Bottlenose Dolphin (Arafura/Timor Sea populations) [78900]		Species or species habitat may occur within area
Migratory Terrestrial Species		
Cecropis daurica Red-rumped Swallow [80610]		Species or species habitat may occur within area
Hirundo rustica Barn Swallow [662]		Species or species habitat may occur within area
Motacilla cinerea Grey Wagtail [642]		Species or species habitat may occur within area
Motacilla flava Yellow Wagtail [644]		Species or species habitat may occur within area
Migratory Wetlands Species		
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat known to occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]		Species or species habitat may occur within area
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat may occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat may occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat may occur within area

Aipysurus eydouxii Spine-tailed Seasnake [1117]		Species or species habitat may occur within area
Aipysurus fuscus Dusky Seasnake [1119]		Species or species habitat known to occur within area
Aipysurus laevis Olive Seasnake [1120]		Species or species habitat may occur within area
Astrotia stokesii Stokes' Seasnake [1122]		Species or species habitat may occur within area
Caretta caretta Loggerhead Turtle [1763]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Disteira kingii Spectacled Seasnake [1123]		Species or species habitat may occur within area
Disteira major Olive-headed Seasnake [1124]		Species or species habitat may occur within area
Emydocephalus annulatus Turtle-headed Seasnake [1125]		Species or species habitat may occur within area
Ephalophis greyi North-western Mangrove Seasnake [1127]		Species or species habitat may occur within area
Eretmochelys imbricata Hawksbill Turtle [1766]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Hydrophis coggeri Slender-necked Seasnake [25925]		Species or species habitat may occur within area
Hydrophis czeblukovi Fine-spined Seasnake [59233]		Species or species habitat may occur within area
Hydrophis elegans Elegant Seasnake [1104]		Species or species habitat may occur within area
Hydrophis mcdowelli null [25926]		Species or species habitat may occur within area
Hydrophis ornatus Spotted Seasnake, Ornate Reef Seasnake [1111]		Species or species habitat may occur within area
Lapemis hardwickii Spine-bellied Seasnake [1113]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
Lepidochelys olivacea Olive Ridley Turtle, Pacific Ridley Turtle [1767]	Endangered	Foraging, feeding or related behaviour likely to occur within area
Natator depressus Flatback Turtle [59257]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Pelamis platurus Yellow-bellied Seasnake [1091]		Species or species habitat may occur within area

Whales and other Cetaceans [Resource Information]

Name	Status	Type of Presence
Mammals		
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera edeni Bryde's Whale [35]		Species or species habitat likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Migration route known to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Delphinus delphis Common Dophin, Short-beaked Common Dolphin [60]		Species or species habitat may occur within area
Feresa attenuata Pygmy Killer Whale [61]		Species or species habitat may occur within area
Globicephala macrorhynchus Short-finned Pilot Whale [62]		Species or species habitat may occur within area
Grampus griseus Risso's Dolphin, Grampus [64]		Species or species habitat may occur within area
Kogia breviceps Pygmy Sperm Whale [57]		Species or species habitat may occur within area
Kogia simus Dwarf Sperm Whale [58]		Species or species habitat may occur within area
Lagenodelphis hosei Fraser's Dolphin, Sarawak Dolphin [41]		Species or species habitat may occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Mesoplodon densirostris Blainville's Beaked Whale, Dense-beaked Whale [74]		Species or species habitat may occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat may occur within area
Peponocephala electra Melon-headed Whale [47]		Species or species

Name	Status	Type of Presence
		habitat may occur within area
Physeter macrocephalus Sperm Whale [59]		Species or species habitat may occur within area
Pseudorca crassidens False Killer Whale [48]		Species or species habitat likely to occur within area
Stenella attenuata Spotted Dolphin, Pantropical Spotted Dolphin [51]		Species or species habitat may occur within area
Stenella coeruleoalba Striped Dolphin, Euphrosyne Dolphin [52]		Species or species habitat may occur within area
Stenella longirostris Long-snouted Spinner Dolphin [29]		Species or species habitat may occur within area
Steno bredanensis Rough-toothed Dolphin [30]		Species or species habitat may occur within area
Tursiops aduncus Indian Ocean Bottlenose Dolphin, Spotted Bottlenose Dolphin [68418]		Species or species habitat may occur within area
Tursiops aduncus (Arafura/Timor Sea populations) Spotted Bottlenose Dolphin (Arafura/Timor Sea populations) [78900]		Species or species habitat may occur within area
Tursiops truncatus s. str. Bottlenose Dolphin [68417]		Species or species habitat may occur within area
Ziphius cavirostris Cuvier's Beaked Whale, Goose-beaked Whale [56]		Species or species habitat may occur within area

Australian Marine Parks

Name	Label
Argo-Rowley Terrace	Multiple Use Zone (IUCN VI)
Kimberley	Multiple Use Zone (IUCN VI)
Mermaid Reef	National Park Zone (IUCN II)

Extra Information

Key Ecological Features (Marine)

[Resource Information]

Key Ecological Features are the parts of the marine ecosystem that are considered to be important for the biodiversity or ecosystem functioning and integrity of the Commonwealth Marine Area.

Name	Region
Ancient coastline at 125 m depth contour	North-west
Continental Slope Demersal Fish Communities	North-west

Name	Region
Mermaid Reef and Commonwealth waters	North-west
Seringapatam Reef and Commonwealth waters in	North-west

Caveat

The information presented in this report has been provided by a range of data sources as acknowledged at the end of the report.

This report is designed to assist in identifying the locations of places which may be relevant in determining obligations under the Environment Protection and Biodiversity Conservation Act 1999. It holds mapped locations of World and National Heritage properties, Wetlands of International and National Importance, Commonwealth and State/Territory reserves, listed threatened, migratory and marine species and listed threatened ecological communities. Mapping of Commonwealth land is not complete at this stage. Maps have been collated from a range of sources at various resolutions.

Not all species listed under the EPBC Act have been mapped (see below) and therefore a report is a general guide only. Where available data supports mapping, the type of presence that can be determined from the data is indicated in general terms. People using this information in making a referral may need to consider the qualifications below and may need to seek and consider other information sources.

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Threatened, migratory and marine species distributions have been derived through a variety of methods. Where distributions are well known and if time permits, maps are derived using either thematic spatial data (i.e. vegetation, soils, geology, elevation, aspect, terrain, etc) together with point locations and described habitat; or environmental modelling (MAXENT or BIOCLIM habitat modelling) using point locations and environmental data layers.

Where very little information is available for species or large number of maps are required in a short time-frame, maps are derived either from 0.04 or 0.02 decimal degree cells; by an automated process using polygon capture techniques (static two kilometre grid cells, alpha-hull and convex hull); or captured manually or by using topographic features (national park boundaries, islands, etc). In the early stages of the distribution mapping process (1999-early 2000s) distributions were defined by degree blocks, 100K or 250K map sheets to rapidly create distribution maps. More reliable distribution mapping methods are used to update these distributions as time permits.

Only selected species covered by the following provisions of the EPBC Act have been mapped:

- migratory and
- marine

The following species and ecological communities have not been mapped and do not appear in reports produced from this database:

- threatened species listed as extinct or considered as vagrants
- some species and ecological communities that have only recently been listed
- some terrestrial species that overfly the Commonwealth marine area
- migratory species that are very widespread, vagrant, or only occur in small numbers

The following groups have been mapped, but may not cover the complete distribution of the species:

- non-threatened seabirds which have only been mapped for recorded breeding sites
- seals which have only been mapped for breeding sites near the Australian continent

Such breeding sites may be important for the protection of the Commonwealth Marine environment.

Chapter 10 C.3 PMST EMBA

Australian Government

Department of the Environment and Energy

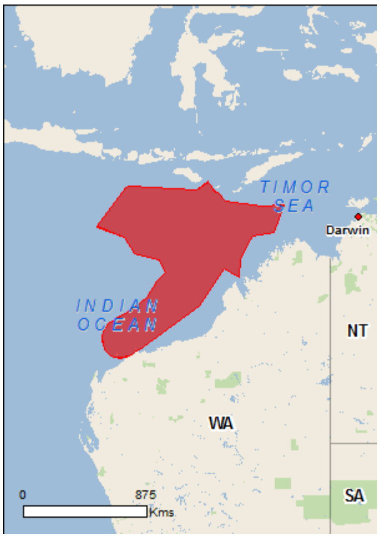
EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected.

Information on the coverage of this report and qualifications on data supporting this report are contained in the caveat at the end of the report.

Information is available about Environment Assessments and the EPBC Act including significance guidelines, forms and application process details.

Report created: 19/11/19 14:03:59



This map may contain data which are ©Commonwealth of Australia (Geoscience Australia), ©PSMA 2010

Coordinates

Buffer: 1.0Km

Summary

Matters of National Environmental Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	None
National Heritage Places:	2
Wetlands of International Importance:	1
Great Barrier Reef Marine Park:	None
Commonwealth Marine Area:	2
Listed Threatened Ecological Communities:	None
Listed Threatened Species:	44
Listed Migratory Species:	64

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at http://www.environment.gov.au/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Land:	1
Commonwealth Heritage Places:	3
Listed Marine Species:	118
Whales and Other Cetaceans:	32
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Australian Marine Parks:	14

Extra Information

This part of the report provides information that may also be relevant to the area you have nominated.

State and Territory Reserves:	15
Regional Forest Agreements:	None
Invasive Species:	13
Nationally Important Wetlands:	2
Key Ecological Features (Marine)	8

Details

Matters of National Environmental Significance

National Heritage Properties [Resource Information]

Name	State	Status
Natural		
The West Kimberley	WA	Listed place
Indigenous		
Dampier Archipelago (including Burrup Peninsula)	WA	Listed place

Wetlands of International Importance (Ramsar) [Resource Information]

Name	Proximity
Ashmore reef national nature reserve	Within Ramsar site

Commonwealth Marine Area [Resource Information]

Approval is required for a proposed activity that is located within the Commonwealth Marine Area which has, will have, or is likely to have a significant impact on the environment. Approval may be required for a proposed action taken outside the Commonwealth Marine Area but which has, may have or is likely to have a significant impact on the environment in the Commonwealth Marine Area. Generally the Commonwealth Marine Area stretches from three nautical miles to two hundred nautical miles from the coast.

Name
EEZ and Territorial Sea
Extended Continental Shelf

Marine Regions [Resource Information]

If you are planning to undertake action in an area in or close to the Commonwealth Marine Area, and a marine bioregional plan has been prepared for the Commonwealth Marine Area in that area, the marine bioregional plan may inform your decision as to whether to refer your proposed action under the EPBC Act.

Name
North-west

Listed Threatened Species [Resource Information]

Name	Status	Type of Presence
Birds		
Anous tenuirostris melanops Australian Lesser Noddy [26000]	Vulnerable	Breeding known to occur within area
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat known to occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat known to occur within area
Limosa lapponica baueri Bar-tailed Godwit (baueri), Western Alaskan Bar-tailed Godwit [86380]	Vulnerable	Species or species habitat known to occur within area
Limosa lapponica menzbieri Northern Siberian Bar-tailed Godwit, Bar-tailed Godwit (menzbieri) [86432]	Critically Endangered	Species or species habitat may occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Malurus leucopterus edouardi White-winged Fairy-wren (Barrow Island), Barrow Island Black-and-white Fairy-wren [26194]	Vulnerable	Species or species habitat likely to occur

Name	Status	Type of Presence
		within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat known to occur within area
Papasula abbotti Abbott's Booby [59297]	Endangered	Species or species habitat may occur within area
Pezoporus occidentalis Night Parrot [59350]	Endangered	Species or species habitat may occur within area
Rostratula australis Australian Painted Snipe [77037]	Endangered	Species or species habitat may occur within area
Sternula nereis nereis Australian Fairy Tern [82950]	Vulnerable	Breeding known to occur within area
Fish		
Milyeringa veritas Blind Gudgeon [66676]	Vulnerable	Species or species habitat may occur within area
Mammals		
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Migration route known to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Bettongia lesueur Barrow and Boodie Islands subspecies Boodie, Burrowing Bettong (Barrow and Boodie Islands) [88021]	Vulnerable	Species or species habitat known to occur within area
Dasyurus hallucatus Northern Quoll, Digul [Gogo-Yimidir], Wijingadda [Dambimangari], Wiminji [Martu] [331]	Endangered	Species or species habitat known to occur within area
Eubalaena australis Southern Right Whale [40]	Endangered	Species or species habitat may occur within area
Isoodon auratus barrowensis Golden Bandicoot (Barrow Island) [66666]	Vulnerable	Species or species habitat known to occur within area
Lagorchestes conspicillatus conspicillatus Spectacled Hare-wallaby (Barrow Island) [66661]	Vulnerable	Species or species habitat known to occur within area
Lagorchestes hirsutus Central Australian subspecies Mala, Rufous Hare-Wallaby (Central Australia) [88019]	Endangered	Translocated population known to occur within area
Macroderma gigas Ghost Bat [174]	Vulnerable	Species or species habitat likely to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Breeding known to occur within area
Osphranter robustus isabellinus Barrow Island Wallaroo, Barrow Island Euro [89262]	Vulnerable	Species or species habitat likely to occur within area

Name	Status	Type of Presence
Petrogale lateralis lateralis		
Black-flanked Rock-wallaby, Moororong, Black-footed Rock Wallaby [66647]	Endangered	Species or species habitat known to occur within area
Rhinonicteris aurantia (Pilbara form)		
Pilbara Leaf-nosed Bat [82790]	Vulnerable	Species or species habitat known to occur within area
Reptiles		
Aipysurus apraefrontalis		
Short-nosed Seasnake [1115]	Critically Endangered	Species or species habitat known to occur within area
Aipysurus foliosquama		
Leaf-scaled Seasnake [1118]	Critically Endangered	Species or species habitat known to occur within area
Caretta caretta		
Loggerhead Turtle [1763]	Endangered	Breeding known to occur within area
Chelonia mydas		
Green Turtle [1765]	Vulnerable	Breeding known to occur within area
Ctenotus zastictus		
Hamelin Ctenotus [25570]	Vulnerable	Species or species habitat known to occur within area
Dermochelys coriacea		
Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Breeding likely to occur within area
Eretmochelys imbricata		
Hawksbill Turtle [1766]	Vulnerable	Breeding known to occur within area
Lepidochelys olivacea		
Olive Ridley Turtle, Pacific Ridley Turtle [1767]	Endangered	Species or species habitat known to occur within area
Liasis olivaceus barroni		
Olive Python (Pilbara subspecies) [66699]	Vulnerable	Species or species habitat known to occur within area
Natator depressus		
Flatback Turtle [59257]	Vulnerable	Breeding known to occur within area
Sharks		
Carcharias taurus (west coast population)		
Grey Nurse Shark (west coast population) [68752]	Vulnerable	Species or species habitat known to occur within area
Carcharodon carcharias		
White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat may occur within area
Glyphis garricki		
Northern River Shark, New Guinea River Shark [82454]	Endangered	Species or species habitat may occur within area
Pristis clavata		
Dwarf Sawfish, Queensland Sawfish [68447]	Vulnerable	Species or species habitat known to occur within area
Pristis pristis		
Freshwater Sawfish, Largetooth Sawfish, River Sawfish, Leichhardt's Sawfish, Northern Sawfish [60756]	Vulnerable	Species or species habitat known to occur within area
Pristis zijsron		
Green Sawfish, Dindagubba, Narrowsnout Sawfish [68442]	Vulnerable	Species or species habitat known to occur within area
Rhincodon typus		
Whale Shark [66680]	Vulnerable	Foraging, feeding or related behaviour known to occur within area

Listed Migratory Species		[Resource Information]
* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.		
Name	Threatened	Type of Presence
Migratory Marine Birds		
Anous stolidus Common Noddy [825]		Breeding known to occur within area
Apus pacificus Fork-tailed Swift [678]		Species or species habitat likely to occur within area
Ardenna pacifica Wedge-tailed Shearwater [84292]		Breeding known to occur within area
Calonectris leucomelas Streaked Shearwater [1077]		Species or species habitat known to occur within area
Fregata ariel Lesser Frigatebird, Least Frigatebird [1012]		Breeding known to occur within area
Fregata minor Great Frigatebird, Greater Frigatebird [1013]		Breeding known to occur within area
Hydroprogne caspia Caspian Tern [808]		Breeding known to occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Onychoprion anaethetus Bridled Tern [82845]		Breeding known to occur within area
Phaethon lepturus White-tailed Tropicbird [1014]		Breeding known to occur within area
Phaethon rubricauda Red-tailed Tropicbird [994]		Breeding known to occur within area
Sterna dougallii Roseate Tern [817]		Breeding known to occur within area
Sternula albifrons Little Tern [82849]		Congregation or aggregation known to occur within area
Sula dactylatra Masked Booby [1021]		Breeding known to occur within area
Sula leucogaster Brown Booby [1022]		Breeding known to occur within area
Sula sula Red-footed Booby [1023]		Breeding known to occur within area
Migratory Marine Species		
Anoxypristis cuspidata Narrow Sawfish, Knifetooth Sawfish [68448]		Species or species habitat known to occur within area
Balaena glacialis australis Southern Right Whale [75529]	Endangered*	Species or species habitat may occur within area
Balaenoptera bonaerensis Antarctic Minke Whale, Dark-shoulder Minke Whale [67812]		Species or species habitat likely to occur within area
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area

Name	Threatened	Type of Presence
Balaenoptera edeni Bryde's Whale [35]		Species or species habitat likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Migration route known to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat may occur within area
Caretta caretta Loggerhead Turtle [1763]	Endangered	Breeding known to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Breeding known to occur within area
Crocodylus porosus Salt-water Crocodile, Estuarine Crocodile [1774]		Species or species habitat likely to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Breeding likely to occur within area
Dugong dugon Dugong [28]		Breeding known to occur within area
Eretmochelys imbricata Hawksbill Turtle [1766]	Vulnerable	Breeding known to occur within area
Isurus oxyrinchus Shortfin Mako, Mako Shark [79073]		Species or species habitat likely to occur within area
Isurus paucus Longfin Mako [82947]		Species or species habitat likely to occur within area
Lepidochelys olivacea Olive Ridley Turtle, Pacific Ridley Turtle [1767]	Endangered	Species or species habitat known to occur within area
Manta alfredi Reef Manta Ray, Coastal Manta Ray, Inshore Manta Ray, Prince Alfred's Ray, Resident Manta Ray [84994]		Species or species habitat known to occur within area
Manta birostris Giant Manta Ray, Chevron Manta Ray, Pacific Manta Ray, Pelagic Manta Ray, Oceanic Manta Ray [84995]		Species or species habitat likely to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Breeding known to occur within area
Natator depressus Flatback Turtle [59257]	Vulnerable	Breeding known to occur within area
Orcaella heinsohni Australian Snubfin Dolphin [81322]		Species or species habitat may occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat may occur within area
Physeter macrocephalus Sperm Whale [59]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
Pristis clavata Dwarf Sawfish, Queensland Sawfish [68447]	Vulnerable	Species or species habitat known to occur within area
Pristis pristis Freshwater Sawfish, Largetooth Sawfish, River Sawfish, Leichhardt's Sawfish, Northern Sawfish [60756]	Vulnerable	Species or species habitat known to occur within area
Pristis zijsron Green Sawfish, Dindagubba, Narrowsnout Sawfish [68442]	Vulnerable	Species or species habitat known to occur within area
Rhincodon typus Whale Shark [66680]	Vulnerable	Foraging, feeding or related behaviour known to occur within area
Sousa chinensis Indo-Pacific Humpback Dolphin [50]		Breeding known to occur within area
Tursiops aduncus (Arafura/Timor Sea populations) Spotted Bottlenose Dolphin (Arafura/Timor Sea populations) [78900]		Species or species habitat known to occur within area
Migratory Terrestrial Species		
Cecropis daurica Red-rumped Swallow [80610]		Species or species habitat may occur within area
Cuculus optatus Oriental Cuckoo, Horsfield's Cuckoo [86651]		Species or species habitat known to occur within area
Hirundo rustica Barn Swallow [662]		Species or species habitat known to occur within area
Motacilla cinerea Grey Wagtail [642]		Species or species habitat known to occur within area
Motacilla flava Yellow Wagtail [644]		Species or species habitat known to occur within area
Migratory Wetlands Species		
Acrocephalus orientalis Oriental Reed-Warbler [59570]		Species or species habitat known to occur within area
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat known to occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]		Species or species habitat known to occur within area
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat known to occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat known to occur within area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat known to occur within area
Charadrius veredus Oriental Plover, Oriental Dotterel [882]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
Glareola maldivarum Oriental Pratincole [840]		Species or species habitat may occur within area
Limosa lapponica Bar-tailed Godwit [844]		Species or species habitat known to occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat known to occur within area
Pandion haliaetus Osprey [952]		Breeding known to occur within area
Thalasseus bergii Crested Tern [83000]		Breeding known to occur within area
Tringa nebularia Common Greenshank, Greenshank [832]		Species or species habitat likely to occur within area

Other Matters Protected by the EPBC Act

Commonwealth Land

[Resource Information]

The Commonwealth area listed below may indicate the presence of Commonwealth land in this vicinity. Due to the unreliability of the data source, all proposals should be checked as to whether it impacts on a Commonwealth area, before making a definitive decision. Contact the State or Territory government land department for further information.

Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat known to occur within area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat known to occur within area
Calonectris leucomelas Streaked Shearwater [1077]		Species or species habitat known to occur within area
Charadrius veredus Oriental Plover, Oriental Dotterel [882]		Species or species habitat may occur within area
Chrysococcyx osculans Black-eared Cuckoo [705]		Species or species habitat likely to occur within area
Fregata ariel Lesser Frigatebird, Least Frigatebird [1012]		Breeding known to occur within area
Fregata minor Great Frigatebird, Greater Frigatebird [1013]		Breeding known to occur within area
Glareola maldivarum Oriental Pratincole [840]		Species or species habitat may occur within area
Haliaeetus leucogaster White-bellied Sea-Eagle [943]		Species or species habitat known to occur within area
Hirundo daurica Red-rumped Swallow [59480]		Species or species habitat may occur within area
Hirundo rustica Barn Swallow [662]		Species or species habitat known to occur within area
Larus novaehollandiae Silver Gull [810]		Breeding known to occur within area
Limosa lapponica Bar-tailed Godwit [844]		Species or species habitat known to occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Merops ornatus Rainbow Bee-eater [670]		Species or species habitat may occur within area
Motacilla cinerea Grey Wagtail [642]		Species or species habitat known to occur within area
Motacilla flava Yellow Wagtail [644]		Species or species

Name	Threatened	Type of Presence
		habitat known to occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat known to occur within area
Pandion haliaetus Osprey [952]		Breeding known to occur within area
Papasula abbotti Abbott's Booby [59297]	Endangered	Species or species habitat may occur within area
Phaethon lepturus White-tailed Tropicbird [1014]		Breeding known to occur within area
Phaethon rubricauda Red-tailed Tropicbird [994]		Breeding known to occur within area
Puffinus pacificus Wedge-tailed Shearwater [1027]		Breeding known to occur within area
Rostratula benghalensis (sensu lato) Painted Snipe [889]	Endangered*	Species or species habitat may occur within area
Sterna albifrons Little Tern [813]		Congregation or aggregation known to occur within area
Sterna anaethetus Bridled Tern [814]		Breeding known to occur within area
Sterna bengalensis Lesser Crested Tern [815]		Breeding known to occur within area
Sterna bergii Crested Tern [816]		Breeding known to occur within area
Sterna caspia Caspian Tern [59467]		Breeding known to occur within area
Sterna dougallii Roseate Tern [817]		Breeding known to occur within area
Sterna fuscata Sooty Tern [794]		Breeding known to occur within area
Sterna nereis Fairy Tern [796]		Breeding known to occur within area
Sula dactylatra Masked Booby [1021]		Breeding known to occur within area
Sula leucogaster Brown Booby [1022]		Breeding known to occur within area
Sula sula Red-footed Booby [1023]		Breeding known to occur within area
Thinornis rubricollis Hooded Plover [59510]		Species or species habitat known to occur within area
Tringa nebularia Common Greenshank, Greenshank [832]		Species or species habitat likely to occur within area
Fish		
Acentronura larsonae Helen's Pygmy Pipehorse [66186]		Species or species habitat may occur within

Name	Threatened	Type of Presence
		area
Bhanotia fasciolata Corrugated Pipefish, Barbed Pipefish [66188]		Species or species habitat may occur within area
Bulbonaricus brauni Braun's Pughead Pipefish, Pug-headed Pipefish [66189]		Species or species habitat may occur within area
Campichthys tricarinatus Three-keel Pipefish [66192]		Species or species habitat may occur within area
Choeroichthys brachysoma Pacific Short-bodied Pipefish, Short-bodied Pipefish [66194]		Species or species habitat may occur within area
Choeroichthys latispinosus Muiron Island Pipefish [66196]		Species or species habitat may occur within area
Choeroichthys suillus Pig-snouted Pipefish [66198]		Species or species habitat may occur within area
Corythoichthys amplexus Fijian Banded Pipefish, Brown-banded Pipefish [66199]		Species or species habitat may occur within area
Corythoichthys flavofasciatus Reticulate Pipefish, Yellow-banded Pipefish, Network Pipefish [66200]		Species or species habitat may occur within area
Corythoichthys intestinalis Australian Messmate Pipefish, Banded Pipefish [66202]		Species or species habitat may occur within area
Corythoichthys schultzi Schultz's Pipefish [66205]		Species or species habitat may occur within area
Cosmocampus banneri Roughridge Pipefish [66206]		Species or species habitat may occur within area
Doryrhamphus dactyliophorus Banded Pipefish, Ringed Pipefish [66210]		Species or species habitat may occur within area
Doryrhamphus excisus Bluestripe Pipefish, Indian Blue-stripe Pipefish, Pacific Blue-stripe Pipefish [66211]		Species or species habitat may occur within area
Doryrhamphus janssi Cleaner Pipefish, Janss' Pipefish [66212]		Species or species habitat may occur within area
Doryrhamphus multiannulatus Many-banded Pipefish [66717]		Species or species habitat may occur within area
Doryrhamphus negrosensis Flagtail Pipefish, Masthead Island Pipefish [66213]		Species or species habitat may occur within area
Festucalex scalaris Ladder Pipefish [66216]		Species or species habitat may occur within area
Filicampus tigris Tiger Pipefish [66217]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
Halicampus brocki Brock's Pipefish [66219]		Species or species habitat may occur within area
Halicampus dunckeri Red-hair Pipefish, Duncker's Pipefish [66220]		Species or species habitat may occur within area
Halicampus grayi Mud Pipefish, Gray's Pipefish [66221]		Species or species habitat may occur within area
Halicampus nitidus Glittering Pipefish [66224]		Species or species habitat may occur within area
Halicampus spinirostris Spiny-snout Pipefish [66225]		Species or species habitat may occur within area
Haliichthys taeniophorus Ribboned Pipehorse, Ribboned Seadragon [66226]		Species or species habitat may occur within area
Hippichthys penicillus Beady Pipefish, Steep-nosed Pipefish [66231]		Species or species habitat may occur within area
Hippocampus angustus Western Spiny Seahorse, Narrow-bellied Seahorse [66234]		Species or species habitat may occur within area
Hippocampus histrix Spiny Seahorse, Thorny Seahorse [66236]		Species or species habitat may occur within area
Hippocampus kuda Spotted Seahorse, Yellow Seahorse [66237]		Species or species habitat may occur within area
Hippocampus planifrons Flat-face Seahorse [66238]		Species or species habitat may occur within area
Hippocampus spinosissimus Hedgehog Seahorse [66239]		Species or species habitat may occur within area
Hippocampus trimaculatus Three-spot Seahorse, Low-crowned Seahorse, Flat-faced Seahorse [66720]		Species or species habitat may occur within area
Micrognathus micronotopterus Tidepool Pipefish [66255]		Species or species habitat may occur within area
Phoxocampus belcheri Black Rock Pipefish [66719]		Species or species habitat may occur within area
Solegnathus hardwickii Pallid Pipehorse, Hardwick's Pipehorse [66272]		Species or species habitat may occur within area
Solegnathus lettiensis Gunther's Pipehorse, Indonesian Pipefish [66273]		Species or species habitat may occur within area
Solenostomus cyanopterus Robust Ghostpipefish, Blue-finned Ghost Pipefish, [66183]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
Syngnathoides biaculeatus Double-end Pipehorse, Double-ended Pipehorse, Alligator Pipefish [66279]		Species or species habitat may occur within area
Trachyrhamphus bicoarctatus Bentstick Pipefish, Bend Stick Pipefish, Short-tailed Pipefish [66280]		Species or species habitat may occur within area
Trachyrhamphus longirostris Straightstick Pipefish, Long-nosed Pipefish, Straight Stick Pipefish [66281]		Species or species habitat may occur within area
Mammals		
Dugong dugon Dugong [28]		Breeding known to occur within area
Reptiles		
Acalyptophis peronii Horned Seasnake [1114]		Species or species habitat may occur within area
Aipysurus apraefrontalis Short-nosed Seasnake [1115]	Critically Endangered	Species or species habitat known to occur within area
Aipysurus duboisii Dubois' Seasnake [1116]		Species or species habitat may occur within area
Aipysurus eydouxii Spine-tailed Seasnake [1117]		Species or species habitat may occur within area
Aipysurus foliosquama Leaf-scaled Seasnake [1118]	Critically Endangered	Species or species habitat known to occur within area
Aipysurus fuscus Dusky Seasnake [1119]		Species or species habitat known to occur within area
Aipysurus laevis Olive Seasnake [1120]		Species or species habitat may occur within area
Aipysurus tenuis Brown-lined Seasnake [1121]		Species or species habitat may occur within area
Astrotia stokesii Stokes' Seasnake [1122]		Species or species habitat may occur within area
Caretta caretta Loggerhead Turtle [1763]	Endangered	Breeding known to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Breeding known to occur within area
Crocodylus porosus Salt-water Crocodile, Estuarine Crocodile [1774]		Species or species habitat likely to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Breeding likely to occur within area
Disteira kingii Spectacled Seasnake [1123]		Species or species habitat may occur within area
Disteira major Olive-headed Seasnake [1124]		Species or species habitat may occur within

Name	Threatened	Type of Presence
		area
Emydocephalus annulatus Turtle-headed Seasnake [1125]		Species or species habitat may occur within area
Enhydrina schistosa Beaked Seasnake [1126]		Species or species habitat may occur within area
Ephalophis greyi North-western Mangrove Seasnake [1127]		Species or species habitat may occur within area
Eretmochelys imbricata Hawksbill Turtle [1766]	Vulnerable	Breeding known to occur within area
Hydrelaps darwiniensis Black-ringed Seasnake [1100]		Species or species habitat may occur within area
Hydrophis atriceps Black-headed Seasnake [1101]		Species or species habitat may occur within area
Hydrophis coggeri Slender-necked Seasnake [25925]		Species or species habitat may occur within area
Hydrophis czeblukovi Fine-spined Seasnake [59233]		Species or species habitat may occur within area
Hydrophis elegans Elegant Seasnake [1104]		Species or species habitat may occur within area
Hydrophis mcdowelli null [25926]		Species or species habitat may occur within area
Hydrophis ornatus Spotted Seasnake, Ornate Reef Seasnake [1111]		Species or species habitat may occur within area
Lapemis hardwickii Spine-bellied Seasnake [1113]		Species or species habitat may occur within area
Lepidochelys olivacea Olive Ridley Turtle, Pacific Ridley Turtle [1767]	Endangered	Species or species habitat known to occur within area
Natator depressus Flatback Turtle [59257]	Vulnerable	Breeding known to occur within area
Pelamis platurus Yellow-bellied Seasnake [1091]		Species or species habitat may occur within area

Whales and other Cetaceans

[Resource Information]

Name	Status	Type of Presence
Mammals		
Balaenoptera acutorostrata Minke Whale [33]		Species or species habitat may occur within area
Balaenoptera bonaerensis Antarctic Minke Whale, Dark-shoulder Minke Whale [67812]		Species or species habitat likely to occur within area

Name	Status	Type of Presence
Balaenoptera borealis Sei Whale [34]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Balaenoptera edeni Bryde's Whale [35]		Species or species habitat likely to occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Migration route known to occur within area
Balaenoptera physalus Fin Whale [37]	Vulnerable	Foraging, feeding or related behaviour likely to occur within area
Delphinus delphis Common Dophin, Short-beaked Common Dolphin [60]		Species or species habitat may occur within area
Eubalaena australis Southern Right Whale [40]	Endangered	Species or species habitat may occur within area
Feresa attenuata Pygmy Killer Whale [61]		Species or species habitat may occur within area
Globicephala macrorhynchus Short-finned Pilot Whale [62]		Species or species habitat may occur within area
Grampus griseus Risso's Dolphin, Grampus [64]		Species or species habitat may occur within area
Indopacetus pacificus Longman's Beaked Whale [72]		Species or species habitat may occur within area
Kogia breviceps Pygmy Sperm Whale [57]		Species or species habitat may occur within area
Kogia simus Dwarf Sperm Whale [58]		Species or species habitat may occur within area
Lagenodelphis hosei Fraser's Dolphin, Sarawak Dolphin [41]		Species or species habitat may occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Breeding known to occur within area
Mesoplodon densirostris Blainville's Beaked Whale, Dense-beaked Whale [74]		Species or species habitat may occur within area
Mesoplodon ginkgodens Gingko-toothed Beaked Whale, Gingko-toothed Whale, Gingko Beaked Whale [59564]		Species or species habitat may occur within area
Orcaella brevirostris Irrawaddy Dolphin [45]		Species or species habitat may occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat may occur within area
Peponocephala electra Melon-headed Whale [47]		Species or species habitat may occur within

Name	Status	Type of Presence
		area
Physeter macrocephalus Sperm Whale [59]		Species or species habitat may occur within area
Pseudorca crassidens False Killer Whale [48]		Species or species habitat likely to occur within area
Sousa chinensis Indo-Pacific Humpback Dolphin [50]		Breeding known to occur within area
Stenella attenuata Spotted Dolphin, Pantropical Spotted Dolphin [51]		Species or species habitat may occur within area
Stenella coeruleoalba Striped Dolphin, Euphrosyne Dolphin [52]		Species or species habitat may occur within area
Stenella longirostris Long-snouted Spinner Dolphin [29]		Species or species habitat may occur within area
Steno bredanensis Rough-toothed Dolphin [30]		Species or species habitat may occur within area
Tursiops aduncus Indian Ocean Bottlenose Dolphin, Spotted Bottlenose Dolphin [68418]		Species or species habitat likely to occur within area
Tursiops aduncus (Arafura/Timor Sea populations) Spotted Bottlenose Dolphin (Arafura/Timor Sea populations) [78900]		Species or species habitat known to occur within area
Tursiops truncatus s. str. Bottlenose Dolphin [68417]		Species or species habitat may occur within area
Ziphius cavirostris Cuvier's Beaked Whale, Goose-beaked Whale [56]		Species or species habitat may occur within area

Invasive Species

[Resource Information]

Weeds reported here are the 20 species of national significance (WoNS), along with other introduced plants that are considered by the States and Territories to pose a particularly significant threat to biodiversity. The following feral animals are reported: Goat, Red Fox, Cat, Rabbit, Pig, Water Buffalo and Cane Toad. Maps from Landscape Health Project, National Land and Water Resouces Audit, 2001.

Name	Status	Type of Presence
Mammals		
Canis lupus familiaris Domestic Dog [82654]		Species or species habitat likely to occur within area
Felis catus Cat, House Cat, Domestic Cat [19]		Species or species habitat likely to occur within area
Mus musculus House Mouse [120]		Species or species habitat likely to occur within area
Oryctolagus cuniculus Rabbit, European Rabbit [128]		Species or species habitat likely to occur within area
Rattus exulans Pacific Rat, Polynesian Rat [79]		Species or species habitat likely to occur within area
Rattus rattus Black Rat, Ship Rat [84]		Species or species habitat likely to occur within area
Vulpes vulpes Red Fox, Fox [18]		Species or species habitat likely to occur within area
Plants		
Cenchrus ciliaris Buffel-grass, Black Buffel-grass [20213]		Species or species habitat likely to occur within area
Jatropha gossypifolia Cotton-leaved Physic-Nut, Bellyache Bush, Cotton-leaf Physic Nut, Cotton-leaf Jatropha, Black Physic Nut [7507]		Species or species habitat likely to occur within area
Opuntia spp. Prickly Pears [82753]		Species or species habitat likely to occur within area

Name	Status	Type of Presence
Parkinsonia aculeata		
Parkinsonia, Jerusalem Thorn, Jelly Bean Tree, Horse Bean [12301]		Species or species habitat likely to occur within area
Prosopis spp.		
Mesquite, Algaroba [68407]		Species or species habitat likely to occur within area
Reptiles		
Ramphotyphlops braminus		
Flowerpot Blind Snake, Brahminy Blind Snake, Cacing Besi [1258]		Species or species habitat likely to occur within area

Nationally Important Wetlands

[Resource Information]

Name	State
Ashmore Reef	EXT
Mermaid Reef	EXT

Key Ecological Features (Marine)

[Resource Information]

Key Ecological Features are the parts of the marine ecosystem that are considered to be important for the biodiversity or ecosystem functioning and integrity of the Commonwealth Marine Area.

Name	Region
Ancient coastline at 125 m depth contour	North-west
Ashmore Reef and Cartier Island and surrounding	North-west
Canyons linking the Argo Abyssal Plain with the	North-west
Carbonate bank and terrace system of the Sahul	North-west
Continental Slope Demersal Fish Communities	North-west
Glomar Shoals	North-west
Mermaid Reef and Commonwealth waters	North-west
Seringapatam Reef and Commonwealth waters in	North-west

Caveat

The information presented in this report has been provided by a range of data sources as acknowledged at the end of the report.

This report is designed to assist in identifying the locations of places which may be relevant in determining obligations under the Environment Protection and Biodiversity Conservation Act 1999. It holds mapped locations of World and National Heritage properties, Wetlands of International and National Importance, Commonwealth and State/Territory reserves, listed threatened, migratory and marine species and listed threatened ecological communities. Mapping of Commonwealth land is not complete at this stage. Maps have been collated from a range of sources at various resolutions.

Not all species listed under the EPBC Act have been mapped (see below) and therefore a report is a general guide only. Where available data supports mapping, the type of presence that can be determined from the data is indicated in general terms. People using this information in making a referral may need to consider the qualifications below and may need to seek and consider other information sources.

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Threatened, migratory and marine species distributions have been derived through a variety of methods. Where distributions are well known and if time permits, maps are derived using either thematic spatial data (i.e. vegetation, soils, geology, elevation, aspect, terrain, etc) together with point locations and described habitat; or environmental modelling (MAXENT or BIOCLIM habitat modelling) using point locations and environmental data layers.

Where very little information is available for species or large number of maps are required in a short time-frame, maps are derived either from 0.04 or 0.02 decimal degree cells; by an automated process using polygon capture techniques (static two kilometre grid cells, alpha-hull and convex hull); or captured manually or by using topographic features (national park boundaries, islands, etc). In the early stages of the distribution mapping process (1999-early 2000s) distributions were defined by degree blocks, 100K or 250K map sheets to rapidly create distribution maps. More reliable distribution mapping methods are used to update these distributions as time permits.

Only selected species covered by the following provisions of the EPBC Act have been mapped:

- migratory and
- marine

The following species and ecological communities have not been mapped and do not appear in reports produced from this database:

- threatened species listed as extinct or considered as vagrants
- some species and ecological communities that have only recently been listed
- some terrestrial species that overfly the Commonwealth marine area
- migratory species that are very widespread, vagrant, or only occur in small numbers

The following groups have been mapped, but may not cover the complete distribution of the species:

- non-threatened seabirds which have only been mapped for recorded breeding sites
- seals which have only been mapped for breeding sites near the Australian continent

Such breeding sites may be important for the protection of the Commonwealth Marine environment.

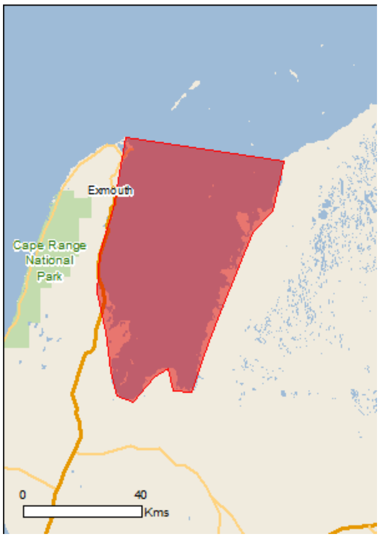
EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected.

Information on the coverage of this report and qualifications on data supporting this report are contained in the caveat at the end of the report.

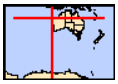
Information is available about Environment Assessments and the EPBC Act including significance guidelines, forms and application process details.

Report created: 16/07/19 09:55:21



This map may contain data which are ©Commonwealth of Australia (Geoscience Australia), ©PSMA 2010

Coordinates
Buffer: 1.0Km



Summary

Matters of National Environmental Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	1
National Heritage Places:	1
Wetlands of International Importance:	None
Great Barrier Reef Marine Park:	None
Commonwealth Marine Area:	None
Listed Threatened Ecological Communities:	None
Listed Threatened Species:	29
Listed Migratory Species:	42

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at http://www.environment.gov.au/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Land:	5
Commonwealth Heritage Places:	None
Listed Marine Species:	79
Whales and Other Cetaceans:	13
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Australian Marine Parks:	None

Extra Information

This part of the report provides information that may also be relevant to the area you have nominated.

State and Territory Reserves:	9
Regional Forest Agreements:	None
Invasive Species:	15
Nationally Important Wetlands:	2
Key Ecological Features (Marine)	None

Mammals		
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Dasyurus hallucatus Northern Quoll, Digul [Gogo-Yimidir], Wijingadda [Dambimangari], Wiminji [Martu] [331]	Endangered	Species or species habitat likely to occur within area
Eubalaena australis Southern Right Whale [40]	Endangered	Species or species habitat likely to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Congregation or aggregation known to occur within area
Petrogale lateralis lateralis Black-flanked Rock-wallaby, Moororong, Black-footed Rock Wallaby [66647]	Endangered	Species or species habitat known to occur within area
Pseudomys fieldi Shark Bay Mouse, Djoongari, Alice Springs Mouse [113]	Vulnerable	Species or species habitat likely to occur within area
Rhinonicteris aurantia (Pilbara form) Pilbara Leaf-nosed Bat [82790]	Vulnerable	Species or species habitat may occur within area
Reptiles		
Aipysurus apraefrontalis Short-nosed Seasnake [1115]	Critically Endangered	Species or species habitat known to occur within area
Caretta caretta Loggerhead Turtle [1763]	Endangered	Breeding known to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Breeding known to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Foraging, feeding or related behaviour known to occur within area
Eretmochelys imbricata Hawksbill Turtle [1766]	Vulnerable	Breeding known to occur within area
Natator depressus Flatback Turtle [59257]	Vulnerable	Breeding known to occur within area
Sharks		
Carcharias taurus (west coast population) Grey Nurse Shark (west coast population) [68752]	Vulnerable	Species or species habitat known to occur within area
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat known to occur within area
Pristis clavata Dwarf Sawfish, Queensland Sawfish [68447]	Vulnerable	Species or species habitat known to occur within area
Pristis zijsron Green Sawfish, Dindagubba, Narrowsnout Sawfish [68442]	Vulnerable	Species or species habitat known to occur within area
Rhincodon typus Whale Shark [66680]	Vulnerable	Species or species habitat may occur within area

Listed Migratory Species [Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Migratory Marine Birds		
Anous stolidus Common Noddy [825]		Species or species habitat likely to occur within area
Apus pacificus Fork-tailed Swift [678]		Species or species habitat likely to occur within area
Ardenna carneipes Flesh-footed Shearwater, Fleshy-footed Shearwater [82404]		Species or species habitat likely to occur within area
Calonectris leucomelas Streaked Shearwater [1077]		Species or species habitat likely to occur within area
Fregata ariel Lesser Frigatebird, Least Frigatebird [1012]		Species or species habitat likely to occur within area
Hydroprogne caspia Caspian Tern [808]		Breeding known to occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Thalassarche impavida Campbell Albatross, Campbell Black-browed Albatross [64459]	Vulnerable	Species or species habitat may occur within area
Migratory Marine Species		
Anoxypristis cuspidata Narrow Sawfish, Knifetooth Sawfish [68448]		Species or species habitat likely to occur within area
Balaena glacialis australis Southern Right Whale [75529]	Endangered*	Species or species habitat likely to occur within area
Balaenoptera edeni Bryde's Whale [35]		Species or species habitat may occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat known to occur within area
Caretta caretta Loggerhead Turtle [1763]	Endangered	Breeding known to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Breeding known to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Foraging, feeding or related behaviour known to occur within area
Dugong dugon Dugong [28]		Breeding known to occur within area
Eretmochelys imbricata Hawksbill Turtle [1766]	Vulnerable	Breeding known to occur within area

Name	Threatened	Type of Presence
Manta alfredi Reef Manta Ray, Coastal Manta Ray, Inshore Manta Ray, Prince Alfred's Ray, Resident Manta Ray [84994]		Species or species habitat known to occur within area
Manta birostris Giant Manta Ray, Chevron Manta Ray, Pacific Manta Ray, Pelagic Manta Ray, Oceanic Manta Ray [84995]		Species or species habitat known to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Congregation or aggregation known to occur within area
Natator depressus Flatback Turtle [59257]	Vulnerable	Breeding known to occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat may occur within area
Pristis clavata Dwarf Sawfish, Queensland Sawfish [68447]	Vulnerable	Species or species habitat known to occur within area
Pristis zijsron Green Sawfish, Dindagubba, Narrowsnout Sawfish [68442]	Vulnerable	Species or species habitat known to occur within area
Rhincodon typus Whale Shark [66680]	Vulnerable	Species or species habitat may occur within area
Sousa chinensis Indo-Pacific Humpback Dolphin [50]		Species or species habitat known to occur within area
Tursiops aduncus (Arafura/Timor Sea populations) Spotted Bottlenose Dolphin (Arafura/Timor Sea populations) [78900]		Species or species habitat known to occur within area
Migratory Terrestrial Species		
Hirundo rustica Barn Swallow [662]		Species or species habitat may occur within area
Motacilla cinerea Grey Wagtail [642]		Species or species habitat may occur within area
Motacilla flava Yellow Wagtail [644]		Species or species habitat may occur within area
Migratory Wetlands Species		
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat known to occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]		Species or species habitat known to occur within area
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat may occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
Charadrius veredus Oriental Plover, Oriental Dotterel [882]		Species or species habitat may occur within area
Glareola maldivarum Oriental Pratincole [840]		Species or species habitat may occur within area
Limosa lapponica Bar-tailed Godwit [844]		Species or species habitat known to occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat known to occur within area
Pandion haliaetus Osprey [952]		Breeding known to occur within area
Tringa nebularia Common Greenshank, Greenshank [832]		Species or species habitat likely to occur within area

Other Matters Protected by the EPBC Act

Commonwealth Land [Resource Information]

The Commonwealth area listed below may indicate the presence of Commonwealth land in this vicinity. Due to the unreliability of the data source, all proposals should be checked as to whether it impacts on a Commonwealth area, before making a definitive decision. Contact the State or Territory government land department for further information.

Filicampus tigris Tiger Pipefish [66217]		Species or species habitat may occur within area
Halicampus brocki Brock's Pipefish [66219]		Species or species habitat may occur within area
Halicampus grayi Mud Pipefish, Gray's Pipefish [66221]		Species or species habitat may occur within area
Halicampus nitidus Glittering Pipefish [66224]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
Halicampus spinirostris Spiny-snout Pipefish [66225]		Species or species habitat may occur within area
Haliichthys taeniophorus Ribboned Pipehorse, Ribboned Seadragon [66226]		Species or species habitat may occur within area
Hippichthys penicillus Beady Pipefish, Steep-nosed Pipefish [66231]		Species or species habitat may occur within area
Hippocampus angustus Western Spiny Seahorse, Narrow-bellied Seahorse [66234]		Species or species habitat may occur within area
Hippocampus histrix Spiny Seahorse, Thorny Seahorse [66236]		Species or species habitat may occur within area
Hippocampus kuda Spotted Seahorse, Yellow Seahorse [66237]		Species or species habitat may occur within area
Hippocampus planifrons Flat-face Seahorse [66238]		Species or species habitat may occur within area
Hippocampus trimaculatus Three-spot Seahorse, Low-crowned Seahorse, Flat-faced Seahorse [66720]		Species or species habitat may occur within area
Micrognathus micronotopterus Tidepool Pipefish [66255]		Species or species habitat may occur within area
Phoxocampus belcheri Black Rock Pipefish [66719]		Species or species habitat may occur within area
Solegnathus hardwickii Pallid Pipehorse, Hardwick's Pipehorse [66272]		Species or species habitat may occur within area
Solegnathus lettiensis Gunther's Pipehorse, Indonesian Pipefish [66273]		Species or species habitat may occur within area
Solenostomus cyanopterus Robust Ghostpipefish, Blue-finned Ghost Pipefish, [66183]		Species or species habitat may occur within area
Syngnathoides biaculeatus Double-end Pipehorse, Double-ended Pipehorse, Alligator Pipefish [66279]		Species or species habitat may occur within area
Trachyrhamphus bicoarctatus Bentstick Pipefish, Bend Stick Pipefish, Short-tailed Pipefish [66280]		Species or species habitat may occur within area
Trachyrhamphus longirostris Straightstick Pipefish, Long-nosed Pipefish, Straight Stick Pipefish [66281]		Species or species habitat may occur within area
Mammals		
Dugong dugon Dugong [28]		Breeding known to occur within area
Reptiles		
Acalyptophis peronii Horned Seasnake [1114]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
Aipysurus apraefrontalis Short-nosed Seasnake [1115]	Critically Endangered	Species or species habitat known to occur within area
Aipysurus duboisii Dubois' Seasnake [1116]		Species or species habitat may occur within area
Aipysurus eydouxii Spine-tailed Seasnake [1117]		Species or species habitat may occur within area
Aipysurus laevis Olive Seasnake [1120]		Species or species habitat may occur within area
Astrotia stokesii Stokes' Seasnake [1122]		Species or species habitat may occur within area
Caretta caretta Loggerhead Turtle [1763]	Endangered	Breeding known to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Breeding known to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Foraging, feeding or related behaviour known to occur within area
Disteira kingii Spectacled Seasnake [1123]		Species or species habitat may occur within area
Disteira major Olive-headed Seasnake [1124]		Species or species habitat may occur within area
Emydocephalus annulatus Turtle-headed Seasnake [1125]		Species or species habitat may occur within area
Ephalophis greyi North-western Mangrove Seasnake [1127]		Species or species habitat may occur within area
Eretmochelys imbricata Hawksbill Turtle [1766]	Vulnerable	Breeding known to occur within area
Hydrophis elegans Elegant Seasnake [1104]		Species or species habitat may occur within area
Hydrophis ornatus Spotted Seasnake, Ornate Reef Seasnake [1111]		Species or species habitat may occur within area
Natator depressus Flatback Turtle [59257]	Vulnerable	Breeding known to occur within area
Pelamis platurus Yellow-bellied Seasnake [1091]		Species or species habitat may occur within area

Whales and other Cetaceans

[Resource Information]

Name	Status	Type of Presence
Mammals		
Balaenoptera acutorostrata Minke Whale [33]		Species or species habitat may occur within area

Name	Status	Type of Presence
Balaenoptera edeni Bryde's Whale [35]		Species or species habitat may occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Delphinus delphis Common Dophin, Short-beaked Common Dolphin [60]		Species or species habitat may occur within area
Eubalaena australis Southern Right Whale [40]	Endangered	Species or species habitat likely to occur within area
Grampus griseus Risso's Dolphin, Grampus [64]		Species or species habitat may occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Congregation or aggregation known to occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat may occur within area
Sousa chinensis Indo-Pacific Humpback Dolphin [50]		Species or species habitat known to occur within area
Stenella attenuata Spotted Dolphin, Pantropical Spotted Dolphin [51]		Species or species habitat may occur within area
Tursiops aduncus Indian Ocean Bottlenose Dolphin, Spotted Bottlenose Dolphin [68418]		Species or species habitat likely to occur within area
Tursiops aduncus (Arafura/Timor Sea populations) Spotted Bottlenose Dolphin (Arafura/Timor Sea populations) [78900]		Species or species habitat known to occur within area
Tursiops truncatus s. str. Bottlenose Dolphin [68417]		Species or species habitat may occur within area

Y Island	WA

Invasive Species

[Resource Information]

Weeds reported here are the 20 species of national significance (WoNS), along with other introduced plants that are considered by the States and Territories to pose a particularly significant threat to biodiversity. The following feral animals are reported: Goat, Red Fox, Cat, Rabbit, Pig, Water Buffalo and Cane Toad. Maps from Landscape Health Project, National Land and Water Resouces Audit, 2001.

Name	Status	Type of Presence
Birds		
Columba livia Rock Pigeon, Rock Dove, Domestic Pigeon [803]		Species or species habitat likely to occur within area
Mammals		
Canis lupus familiaris Domestic Dog [82654]		Species or species habitat likely to occur within area
Capra hircus Goat [2]		Species or species habitat likely to occur within area
Equus asinus Donkey, Ass [4]		Species or species habitat likely to occur within area
Equus caballus Horse [5]		Species or species habitat likely to occur within area
Felis catus Cat, House Cat, Domestic Cat [19]		Species or species habitat likely to occur within area
Mus musculus House Mouse [120]		Species or species habitat likely to occur within area
Oryctolagus cuniculus Rabbit, European Rabbit [128]		Species or species habitat likely to occur within area
Rattus rattus Black Rat, Ship Rat [84]		Species or species habitat likely to occur within area
Vulpes vulpes Red Fox, Fox [18]		Species or species habitat likely to occur within area
Plants		
Cenchrus ciliaris Buffel-grass, Black Buffel-grass [20213]		Species or species habitat likely to occur within area
Parkinsonia aculeata Parkinsonia, Jerusalem Thorn, Jelly Bean Tree, Horse Bean [12301]		Species or species habitat likely to occur within area
Prosopis spp. Mesquite, Algaroba [68407]		Species or species habitat likely to occur within area
Reptiles		
Hemidactylus frenatus Asian House Gecko [1708]		Species or species habitat likely to occur within area
Ramphotyphlops braminus Flowerpot Blind Snake, Brahminy Blind Snake, Cacing Besi [1258]		Species or species habitat may occur within area

Caveat

The information presented in this report has been provided by a range of data sources as acknowledged at the end of the report.

This report is designed to assist in identifying the locations of places which may be relevant in determining obligations under the Environment Protection and Biodiversity Conservation Act 1999. It holds mapped locations of World and National Heritage properties, Wetlands of International and National Importance, Commonwealth and State/Territory reserves, listed threatened, migratory and marine species and listed threatened ecological communities. Mapping of Commonwealth land is not complete at this stage. Maps have been collated from a range of sources at various resolutions.

Not all species listed under the EPBC Act have been mapped (see below) and therefore a report is a general guide only. Where available data supports mapping, the type of presence that can be determined from the data is indicated in general terms. People using this information in making a referral may need to consider the qualifications below and may need to seek and consider other information sources.

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Threatened, migratory and marine species distributions have been derived through a variety of methods. Where distributions are well known and if time permits, maps are derived using either thematic spatial data (i.e. vegetation, soils, geology, elevation, aspect, terrain, etc) together with point locations and described habitat; or environmental modelling (MAXENT or BIOCLIM habitat modelling) using point locations and environmental data layers.

Where very little information is available for species or large number of maps are required in a short time-frame, maps are derived either from 0.04 or 0.02 decimal degree cells; by an automated process using polygon capture techniques (static two kilometre grid cells, alpha-hull and convex hull); or captured manually or by using topographic features (national park boundaries, islands, etc). In the early stages of the distribution mapping process (1999-early 2000s) distributions were defined by degree blocks, 100K or 250K map sheets to rapidly create distribution maps. More reliable distribution mapping methods are used to update these distributions as time permits.

Only selected species covered by the following provisions of the EPBC Act have been mapped:

- migratory and
- marine

The following species and ecological communities have not been mapped and do not appear in reports produced from this database:

- threatened species listed as extinct or considered as vagrants
- some species and ecological communities that have only recently been listed
- some terrestrial species that overfly the Commonwealth marine area
- migratory species that are very widespread, vagrant, or only occur in small numbers

The following groups have been mapped, but may not cover the complete distribution of the species:

- non-threatened seabirds which have only been mapped for recorded breeding sites
- seals which have only been mapped for breeding sites near the Australian continent

Such breeding sites may be important for the protection of the Commonwealth Marine environment.

EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected.

Information on the coverage of this report and qualifications on data supporting this report are contained in the caveat at the end of the report.

Information is available about Environment Assessments and the EPBC Act including significance guidelines, forms and application process details.

Report created: 02/05/19 18:52:55

Summary

Matters of National Environmental Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	None
National Heritage Places:	1
Wetlands of International Importance:	1
Great Barrier Reef Marine Park:	None
Commonwealth Marine Area:	1
Listed Threatened Ecological Communities:	1
Listed Threatened Species:	31
Listed Migratory Species:	65

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at http://www.environment.gov.au/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Land:	2
Commonwealth Heritage Places:	None
Listed Marine Species:	104
Whales and Other Cetaceans:	12
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Australian Marine Parks:	1

Extra Information

This part of the report provides information that may also be relevant to the area you have nominated.

State and Territory Reserves:	3
Regional Forest Agreements:	None
Invasive Species:	12
Nationally Important Wetlands:	1
Key Ecological Features (Marine)	None

Details

Matters of National Environmental Significance

National Heritage Properties [Resource Information]

Name	State	Status
Natural		
The West Kimberley	WA	Listed place

Wetlands of International Importance (Ramsar) [Resource Information]

Name	Proximity
Roebuck bay	Within Ramsar site

Commonwealth Marine Area [Resource Information]

Approval is required for a proposed activity that is located within the Commonwealth Marine Area which has, will have, or is likely to have a significant impact on the environment. Approval may be required for a proposed action taken outside the Commonwealth Marine Area but which has, may have or is likely to have a significant impact on the environment in the Commonwealth Marine Area. Generally the Commonwealth Marine Area stretches from three nautical miles to two hundred nautical miles from the coast.

Name
EEZ and Territorial Sea

Marine Regions [Resource Information]

If you are planning to undertake action in an area in or close to the Commonwealth Marine Area, and a marine bioregional plan has been prepared for the Commonwealth Marine Area in that area, the marine bioregional plan may inform your decision as to whether to refer your proposed action under the EPBC Act.

Name
North-west

Listed Threatened Ecological Communities [Resource Information]

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Name	Status	Type of Presence
Monsoon vine thickets on the coastal sand dunes of Dampier Peninsula	Endangered	Community likely to occur within area

Listed Threatened Species [Resource Information]

Name	Status	Type of Presence
Birds		
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat known to occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat known to occur within area
Calidris tenuirostris Great Knot [862]	Critically Endangered	Roosting known to occur within area
Charadrius leschenaultii Greater Sand Plover, Large Sand Plover [877]	Vulnerable	Roosting known to occur within area
Charadrius mongolus Lesser Sand Plover, Mongolian Plover [879]	Endangered	Roosting known to occur within area
Erythrura gouldiae Gouldian Finch [413]	Endangered	Species or species habitat may occur within area

Name	Status	Type of Presence
Limosa lapponica baueri Bar-tailed Godwit (baueri), Western Alaskan Bar-tailed Godwit [86380]	Vulnerable	Species or species habitat known to occur within area
Limosa lapponica menzbieri Northern Siberian Bar-tailed Godwit, Bar-tailed Godwit (menzbieri) [86432]	Critically Endangered	Species or species habitat known to occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat known to occur within area
Papasula abbotti Abbott's Booby [59297]	Endangered	Species or species habitat may occur within area
Polytelis alexandrae Princess Parrot, Alexandra's Parrot [758]	Vulnerable	Species or species habitat likely to occur within area
Rostratula australis Australian Painted-snipe, Australian Painted Snipe [77037]	Endangered	Species or species habitat likely to occur within area
Tyto novaehollandiae kimberli Masked Owl (northern) [26048]	Vulnerable	Species or species habitat may occur within area
Mammals		
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Macrotis lagotis Greater Bilby [282]	Vulnerable	Species or species habitat known to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Saccolaimus saccolaimus nudicluniatus Bare-rumped Sheath-tailed Bat, Bare-rumped Sheathtail Bat [66889]	Vulnerable	Species or species habitat likely to occur within area
Xeromys myoides Water Mouse, False Water Rat, Yirrkoo [66]	Vulnerable	Species or species habitat may occur within area
Plants		
Keraudrenia exastia Fringed Keraudrenia [66301]	Critically Endangered	Species or species habitat known to occur within area
Reptiles		
Aipysurus apraefrontalis Short-nosed Seasnake [1115]	Critically Endangered	Species or species habitat likely to occur within area
Caretta caretta Loggerhead Turtle [1763]	Endangered	Foraging, feeding or related behaviour known to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Breeding known to occur within area
Ctenotus angusticeps Northwestern Coastal Ctenotus, Airlie Island Ctenotus [25937]	Vulnerable	Species or species habitat likely to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Breeding likely to occur within area

Name	Status	Type of Presence
Eretmochelys imbricata Hawksbill Turtle [1766]	Vulnerable	Breeding likely to occur within area
Natator depressus Flatback Turtle [59257]	Vulnerable	Breeding known to occur within area
Sharks		
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat may occur within area
Pristis clavata Dwarf Sawfish, Queensland Sawfish [68447]	Vulnerable	Species or species habitat known to occur within area
Pristis pristis Freshwater Sawfish, Largetooth Sawfish, River Sawfish, Leichhardt's Sawfish, Northern Sawfish [60756]	Vulnerable	Species or species habitat known to occur within area
Pristis zijsron Green Sawfish, Dindagubba, Narrowsnout Sawfish [68442]	Vulnerable	Breeding known to occur within area
Rhincodon typus Whale Shark [66680]	Vulnerable	Species or species habitat may occur within area

Listed Migratory Species [Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Migratory Marine Birds		
Anous stolidus Common Noddy [825]		Species or species habitat likely to occur within area
Apus pacificus Fork-tailed Swift [678]		Species or species habitat likely to occur within area
Calonectris leucomelas Streaked Shearwater [1077]		Species or species habitat known to occur within area
Fregata ariel Lesser Frigatebird, Least Frigatebird [1012]		Species or species habitat known to occur within area
Fregata minor Great Frigatebird, Greater Frigatebird [1013]		Species or species habitat known to occur within area
Sternula albifrons Little Tern [82849]		Breeding known to occur within area
Migratory Marine Species		
Anoxypristis cuspidata Narrow Sawfish, Knifetooth Sawfish [68448]		Species or species habitat likely to occur within area
Balaenoptera edeni Bryde's Whale [35]		Species or species habitat may occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat may occur within area

Name	Threatened	Type of Presence
Caretta caretta Loggerhead Turtle [1763]	Endangered	Foraging, feeding or related behaviour known to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Breeding known to occur within area
Crocodylus porosus Salt-water Crocodile, Estuarine Crocodile [1774]		Species or species habitat likely to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Breeding likely to occur within area
Dugong dugon Dugong [28]		Foraging, feeding or related behaviour known to occur within area
Eretmochelys imbricata Hawksbill Turtle [1766]	Vulnerable	Breeding likely to occur within area
Manta alfredi Reef Manta Ray, Coastal Manta Ray, Inshore Manta Ray, Prince Alfred's Ray, Resident Manta Ray [84994]		Species or species habitat may occur within area
Manta birostris Giant Manta Ray, Chevron Manta Ray, Pacific Manta Ray, Pelagic Manta Ray, Oceanic Manta Ray [84995]		Species or species habitat may occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Natator depressus Flatback Turtle [59257]	Vulnerable	Breeding known to occur within area
Orcaella heinsohni Australian Snubfin Dolphin [81322]		Species or species habitat known to occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat may occur within area
Pristis clavata Dwarf Sawfish, Queensland Sawfish [68447]	Vulnerable	Species or species habitat known to occur within area
Pristis pristis Freshwater Sawfish, Largetooth Sawfish, River Sawfish, Leichhardt's Sawfish, Northern Sawfish [60756]	Vulnerable	Species or species habitat known to occur within area
Pristis zijsron Green Sawfish, Dindagubba, Narrowsnout Sawfish [68442]	Vulnerable	Breeding known to occur within area
Rhincodon typus Whale Shark [66680]	Vulnerable	Species or species habitat may occur within area
Sousa chinensis Indo-Pacific Humpback Dolphin [50]		Breeding known to occur within area
Tursiops aduncus (Arafura/Timor Sea populations) Spotted Bottlenose Dolphin (Arafura/Timor Sea populations) [78900]		Species or species habitat known to occur within area
Migratory Terrestrial Species		
Cecropis daurica Red-rumped Swallow [80610]		Species or species habitat known to occur within area
Cuculus optatus Oriental Cuckoo, Horsfield's Cuckoo [86651]		Species or species

Name	Threatened	Type of Presence
		habitat known to occur within area
Hirundo rustica Barn Swallow [662]		Species or species habitat known to occur within area
Motacilla cinerea Grey Wagtail [642]		Species or species habitat may occur within area
Motacilla flava Yellow Wagtail [644]		Species or species habitat known to occur within area
Migratory Wetlands Species		
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat known to occur within area
Arenaria interpres Ruddy Turnstone [872]		Roosting known to occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]		Roosting known to occur within area
Calidris alba Sanderling [875]		Roosting known to occur within area
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat known to occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat known to occur within area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat known to occur within area
Calidris ruficollis Red-necked Stint [860]		Roosting known to occur within area
Calidris tenuirostris Great Knot [862]	Critically Endangered	Roosting known to occur within area
Charadrius bicinctus Double-banded Plover [895]		Roosting known to occur within area
Charadrius leschenaultii Greater Sand Plover, Large Sand Plover [877]	Vulnerable	Roosting known to occur within area
Charadrius mongolus Lesser Sand Plover, Mongolian Plover [879]	Endangered	Roosting known to occur within area
Charadrius veredus Oriental Plover, Oriental Dotterel [882]		Roosting known to occur within area
Gallinago megala Swinhoe's Snipe [864]		Roosting likely to occur within area
Gallinago stenura Pin-tailed Snipe [841]		Roosting likely to occur within area
Glareola maldivarum Oriental Pratincole [840]		Roosting known to occur within area
Limicola falcinellus Broad-billed Sandpiper [842]		Roosting known to occur within area
Limnodromus semipalmatus Asian Dowitcher [843]		Roosting known to occur

Name	Threatened	Type of Presence
		within area
Limosa lapponica Bar-tailed Godwit [844]		Species or species habitat known to occur within area
Limosa limosa Black-tailed Godwit [845]		Roosting known to occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat known to occur within area
Numenius minutus Little Curlew, Little Whimbrel [848]		Roosting known to occur within area
Numenius phaeopus Whimbrel [849]		Roosting known to occur within area
Pandion haliaetus Osprey [952]		Breeding known to occur within area
Pluvialis fulva Pacific Golden Plover [25545]		Roosting known to occur within area
Pluvialis squatarola Grey Plover [865]		Roosting known to occur within area
Tringa brevipes Grey-tailed Tattler [851]		Roosting known to occur within area
Tringa glareola Wood Sandpiper [829]		Roosting known to occur within area
Tringa nebularia Common Greenshank, Greenshank [832]		Species or species habitat known to occur within area
Tringa stagnatilis Marsh Sandpiper, Little Greenshank [833]		Roosting known to occur within area
Tringa totanus Common Redshank, Redshank [835]		Roosting known to occur within area
Xenus cinereus Terek Sandpiper [59300]		Roosting known to occur within area

Other Matters Protected by the EPBC Act

Commonwealth Land [Resource Information]

The Commonwealth area listed below may indicate the presence of Commonwealth land in this vicinity. Due to the unreliability of the data source, all proposals should be checked as to whether it impacts on a Commonwealth area, before making a definitive decision. Contact the State or Territory government land department for further information.

Name
Commonwealth Land - Defence - BROOME TRAINING DEPOT

Listed Marine Species [Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Birds		
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat known to occur within area
Anous stolidus Common Noddy [825]		Species or species habitat likely to occur

Name	Threatened	Type of Presence
		within area
Anseranas semipalmata Magpie Goose [978]		Species or species habitat may occur within area
Apus pacificus Fork-tailed Swift [678]		Species or species habitat likely to occur within area
Ardea alba Great Egret, White Egret [59541]		Species or species habitat known to occur within area
Ardea ibis Cattle Egret [59542]		Species or species habitat may occur within area
Arenaria interpres Ruddy Turnstone [872]		Roosting known to occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]		Roosting known to occur within area
Calidris alba Sanderling [875]		Roosting known to occur within area
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat known to occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat known to occur within area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat known to occur within area
Calidris ruficollis Red-necked Stint [860]		Roosting known to occur within area
Calidris tenuirostris Great Knot [862]	Critically Endangered	Roosting known to occur within area
Calonectris leucomelas Streaked Shearwater [1077]		Species or species habitat known to occur within area

Gallinago stenura Pin-tailed Snipe [841]		Roosting likely to occur within area
Glareola maldivarum Oriental Pratincole [840]		Roosting known to occur within area
Haliaeetus leucogaster White-bellied Sea-Eagle [943]		Species or species habitat known to occur within area
Heteroscelus brevipes Grey-tailed Tattler [59311]		Roosting known to occur within area
Himantopus himantopus Pied Stilt, Black-winged Stilt [870]		Roosting known to occur within area
Hirundo daurica Red-rumped Swallow [59480]		Species or species habitat known to occur within area
Hirundo rustica Barn Swallow [662]		Species or species habitat known to occur within area
Limicola falcinellus Broad-billed Sandpiper [842]		Roosting known to occur within area
Limnodromus semipalmatus Asian Dowitcher [843]		Roosting known to occur within area
Limosa lapponica Bar-tailed Godwit [844]		Species or species habitat known to occur within area
Limosa limosa Black-tailed Godwit [845]		Roosting known to occur within area
Merops ornatus Rainbow Bee-eater [670]		Species or species habitat may occur within area
Motacilla cinerea Grey Wagtail [642]		Species or species habitat may occur within area
Motacilla flava Yellow Wagtail [644]		Species or species habitat known to occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat known to occur within area
Numenius minutus Little Curlew, Little Whimbrel [848]		Roosting known to occur within area
Numenius phaeopus Whimbrel [849]		Roosting known to occur within area
Pandion haliaetus Osprey [952]		Breeding known to occur within area
Papasula abbotti Abbott's Booby [59297]	Endangered	Species or species habitat may occur within area

Name	Threatened	Type of Presence
Pluvialis fulva Pacific Golden Plover [25545]		Roosting known to occur within area
Pluvialis squatarola Grey Plover [865]		Roosting known to occur within area
Recurvirostra novaehollandiae Red-necked Avocet [871]		Roosting known to occur within area
Rostratula benghalensis (sensu lato) Painted Snipe [889]	Endangered*	Species or species habitat likely to occur within area
Sterna albifrons Little Tern [813]		Breeding known to occur within area
Tringa glareola Wood Sandpiper [829]		Roosting known to occur within area
Tringa nebularia Common Greenshank, Greenshank [832]		Species or species habitat known to occur within area
Tringa stagnatilis Marsh Sandpiper, Little Greenshank [833]		Roosting known to occur within area
Tringa totanus Common Redshank, Redshank [835]		Roosting known to occur within area
Xenus cinereus Terek Sandpiper [59300]		Roosting known to occur within area
Fish		
Campichthys tricarinatus Three-keel Pipefish [66192]		Species or species habitat may occur within area
Choeroichthys brachysoma Pacific Short-bodied Pipefish, Short-bodied Pipefish [66194]		Species or species habitat may occur within area
Choeroichthys suillus Pig-snouted Pipefish [66198]		Species or species habitat may occur within area
Corythoichthys flavofasciatus Reticulate Pipefish, Yellow-banded Pipefish, Network Pipefish [66200]		Species or species habitat may occur within area
Cosmocampus banneri Roughridge Pipefish [66206]		Species or species habitat may occur within area
Doryrhamphus excisus Bluestripe Pipefish, Indian Blue-stripe Pipefish, Pacific Blue-stripe Pipefish [66211]		Species or species habitat may occur within area
Doryrhamphus janssi Cleaner Pipefish, Janss' Pipefish [66212]		Species or species habitat may occur within area
Filicampus tigris Tiger Pipefish [66217]		Species or species habitat may occur within area
Halicampus brocki Brock's Pipefish [66219]		Species or species habitat may occur within area
Halicampus grayi Mud Pipefish, Gray's Pipefish [66221]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
Halicampus nitidus Glittering Pipefish [66224]		Species or species habitat may occur within area
Halicampus spinirostris Spiny-snout Pipefish [66225]		Species or species habitat may occur within area
Haliichthys taeniophorus Ribboned Pipehorse, Ribboned Seadragon [66226]		Species or species habitat may occur within area
Hippichthys penicillus Beady Pipefish, Steep-nosed Pipefish [66231]		Species or species habitat may occur within area
Hippocampus histrix Spiny Seahorse, Thorny Seahorse [66236]		Species or species habitat may occur within area
Hippocampus kuda Spotted Seahorse, Yellow Seahorse [66237]		Species or species habitat may occur within area
Hippocampus planifrons Flat-face Seahorse [66238]		Species or species habitat may occur within area
Hippocampus spinosissimus Hedgehog Seahorse [66239]		Species or species habitat may occur within area
Hippocampus trimaculatus Three-spot Seahorse, Low-crowned Seahorse, Flat-faced Seahorse [66720]		Species or species habitat may occur within area
Micrognathus micronotopterus Tidepool Pipefish [66255]		Species or species habitat may occur within area
Solegnathus hardwickii Pallid Pipehorse, Hardwick's Pipehorse [66272]		Species or species habitat may occur within area
Solegnathus lettiensis Gunther's Pipehorse, Indonesian Pipefish [66273]		Species or species habitat may occur within area
Solenostomus cyanopterus Robust Ghostpipefish, Blue-finned Ghost Pipefish, [66183]		Species or species habitat may occur within area
Syngnathoides biaculeatus Double-end Pipehorse, Double-ended Pipehorse, Alligator Pipefish [66279]		Species or species habitat may occur within area
Trachyrhamphus bicoarctatus Bentstick Pipefish, Bend Stick Pipefish, Short-tailed Pipefish [66280]		Species or species habitat may occur within area
Trachyrhamphus longirostris Straightstick Pipefish, Long-nosed Pipefish, Straight Stick Pipefish [66281]		Species or species habitat may occur within area
Mammals		
Dugong dugon Dugong [28]		Foraging, feeding or related behaviour known to occur within area
Reptiles		
Acalyptophis peronii Horned Seasnake [1114]		Species or species habitat may occur within

Name	Threatened	Type of Presence
		area
Aipysurus apraefrontalis Short-nosed Seasnake [1115]	Critically Endangered	Species or species habitat likely to occur within area
Aipysurus duboisii Dubois' Seasnake [1116]		Species or species habitat may occur within area
Aipysurus eydouxii Spine-tailed Seasnake [1117]		Species or species habitat may occur within area
Aipysurus laevis Olive Seasnake [1120]		Species or species habitat may occur within area
Aipysurus tenuis Brown-lined Seasnake [1121]		Species or species habitat may occur within area
Astrotia stokesii Stokes' Seasnake [1122]		Species or species habitat may occur within area
Caretta caretta Loggerhead Turtle [1763]	Endangered	Foraging, feeding or related behaviour known to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Breeding known to occur within area
Crocodylus johnstoni Freshwater Crocodile, Johnston's Crocodile, Johnston's River Crocodile [1773]		Species or species habitat may occur within area
Crocodylus porosus Salt-water Crocodile, Estuarine Crocodile [1774]		Species or species habitat likely to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Breeding likely to occur within area
Disteira kingii Spectacled Seasnake [1123]		Species or species habitat may occur within area
Disteira major Olive-headed Seasnake [1124]		Species or species habitat may occur within area
Emydocephalus annulatus Turtle-headed Seasnake [1125]		Species or species habitat may occur within area
Ephalophis greyi North-western Mangrove Seasnake [1127]		Species or species habitat may occur within area
Eretmochelys imbricata Hawksbill Turtle [1766]	Vulnerable	Breeding likely to occur within area
Hydrelaps darwiniensis Black-ringed Seasnake [1100]		Species or species habitat may occur within area
Hydrophis elegans Elegant Seasnake [1104]		Species or species habitat may occur within area
Hydrophis mcdowelli null [25926]		Species or species habitat may occur within

Name	Threatened	Type of Presence
		area
Hydrophis ornatus Spotted Seasnake, Ornate Reef Seasnake [1111]		Species or species habitat may occur within area
Lapemis hardwickii Spine-bellied Seasnake [1113]		Species or species habitat may occur within area
Natator depressus Flatback Turtle [59257]	Vulnerable	Breeding known to occur within area
Pelamis platurus Yellow-bellied Seasnake [1091]		Species or species habitat may occur within area

Whales and other Cetaceans [Resource Information]

Name	Status	Type of Presence
Mammals		
Balaenoptera edeni Bryde's Whale [35]		Species or species habitat may occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Delphinus delphis Common Dophin, Short-beaked Common Dolphin [60]		Species or species habitat may occur within area
Grampus griseus Risso's Dolphin, Grampus [64]		Species or species habitat may occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Orcaella brevirostris Irrawaddy Dolphin [45]		Species or species habitat known to occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat may occur within area
Sousa chinensis Indo-Pacific Humpback Dolphin [50]		Breeding known to occur within area
Stenella attenuata Spotted Dolphin, Pantropical Spotted Dolphin [51]		Species or species habitat may occur within area
Tursiops aduncus Indian Ocean Bottlenose Dolphin, Spotted Bottlenose Dolphin [68418]		Species or species habitat likely to occur within area
Tursiops aduncus (Arafura/Timor Sea populations) Spotted Bottlenose Dolphin (Arafura/Timor Sea populations) [78900]		Species or species habitat known to occur within area
Tursiops truncatus s. str. Bottlenose Dolphin [68417]		Species or species habitat may occur within area

Invasive Species [Resource Information]

Weeds reported here are the 20 species of national significance (WoNS), along with other introduced plants that are considered by the States and Territories to pose a particularly significant threat to biodiversity. The following feral animals are reported: Goat, Red Fox, Cat, Rabbit, Pig, Water Buffalo and Cane Toad. Maps from Landscape Health Project, National Land and Water Resouces Audit, 2001.

Name	Status	Type of Presence
Birds		
Columba livia Rock Pigeon, Rock Dove, Domestic Pigeon [803]		Species or species habitat likely to occur within area
Sturnus vulgaris Common Starling [389]		Species or species habitat likely to occur within area
Frogs		
Rhinella marina Cane Toad [83218]		Species or species habitat may occur within area
Mammals		
Canis lupus familiaris Domestic Dog [82654]		Species or species habitat likely to occur within area
Felis catus Cat, House Cat, Domestic Cat [19]		Species or species habitat likely to occur within area
Mus musculus House Mouse [120]		Species or species habitat likely to occur within area
Rattus rattus Black Rat, Ship Rat [84]		Species or species habitat likely to occur within area
Plants		
Cenchrus ciliaris Buffel-grass, Black Buffel-grass [20213]		Species or species habitat likely to occur within area
Dolichandra unguis-cati Cat's Claw Vine, Yellow Trumpet Vine, Cat's Claw		Species or species

Name	Status	Type of Presence
Creeper, Funnel Creeper [85119]		habitat likely to occur within area
Jatropha gossypifolia		
Cotton-leaved Physic-Nut, Bellyache Bush, Cotton-leaf Physic Nut, Cotton-leaf Jatropha, Black Physic Nut [7507]		Species or species habitat likely to occur within area
Reptiles		
Hemidactylus frenatus		
Asian House Gecko [1708]		Species or species habitat likely to occur within area
Ramphotyphlops braminus		
Flowerpot Blind Snake, Brahminy Blind Snake, Cacing Besi [1258]		Species or species habitat known to occur within area

Nationally Important Wetlands

[Resource Information]

Name	State
Roebuck Bay	WA

Caveat

The information presented in this report has been provided by a range of data sources as acknowledged at the end of the report.

This report is designed to assist in identifying the locations of places which may be relevant in determining obligations under the Environment Protection and Biodiversity Conservation Act 1999. It holds mapped locations of World and National Heritage properties, Wetlands of International and National Importance, Commonwealth and State/Territory reserves, listed threatened, migratory and marine species and listed threatened ecological communities. Mapping of Commonwealth land is not complete at this stage. Maps have been collated from a range of sources at various resolutions.

Not all species listed under the EPBC Act have been mapped (see below) and therefore a report is a general guide only. Where available data supports mapping, the type of presence that can be determined from the data is indicated in general terms. People using this information in making a referral may need to consider the qualifications below and may need to seek and consider other information sources.

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Threatened, migratory and marine species distributions have been derived through a variety of methods. Where distributions are well known and if time permits, maps are derived using either thematic spatial data (i.e. vegetation, soils, geology, elevation, aspect, terrain, etc) together with point locations and described habitat; or environmental modelling (MAXENT or BIOCLIM habitat modelling) using point locations and environmental data layers.

Where very little information is available for species or large number of maps are required in a short time-frame, maps are derived either from 0.04 or 0.02 decimal degree cells; by an automated process using polygon capture techniques (static two kilometre grid cells, alpha-hull and convex hull); or captured manually or by using topographic features (national park boundaries, islands, etc). In the early stages of the distribution mapping process (1999-early 2000s) distributions were defined by degree blocks, 100K or 250K map sheets to rapidly create distribution maps. More reliable distribution mapping methods are used to update these distributions as time permits.

Only selected species covered by the following provisions of the EPBC Act have been mapped:

- migratory and
- marine

The following species and ecological communities have not been mapped and do not appear in reports produced from this database:

- threatened species listed as extinct or considered as vagrants
- some species and ecological communities that have only recently been listed
- some terrestrial species that overfly the Commonwealth marine area
- migratory species that are very widespread, vagrant, or only occur in small numbers

The following groups have been mapped, but may not cover the complete distribution of the species:

- non-threatened seabirds which have only been mapped for recorded breeding sites
- seals which have only been mapped for breeding sites near the Australian continent

Such breeding sites may be important for the protection of the Commonwealth Marine environment.

Chapter 10 C.6 PSMT Port of Dampier

Australian Government
Department of the Environment and Energy

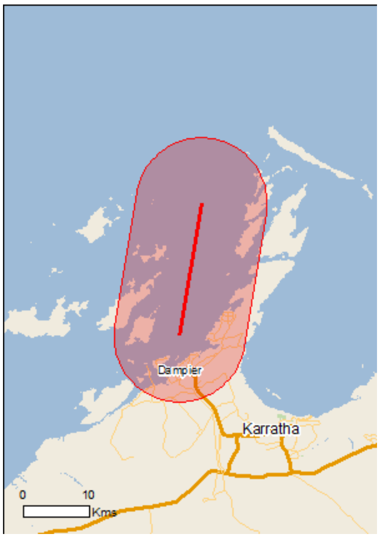
EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected.

Information on the coverage of this report and qualifications on data supporting this report are contained in the caveat at the end of the report.

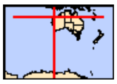
Information is available about Environment Assessments and the EPBC Act including significance guidelines, forms and application process details.

Report created: 02/05/19 18:39:40



This map may contain data which are ©Commonwealth of Australia (Geoscience Australia), ©PSMA 2010

Coordinates
Buffer: 10.0Km



Summary

Matters of National Environmental Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	None
National Heritage Places:	1
Wetlands of International Importance:	None
Great Barrier Reef Marine Park:	None
Commonwealth Marine Area:	None
Listed Threatened Ecological Communities:	None
Listed Threatened Species:	31
Listed Migratory Species:	60

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at http://www.environment.gov.au/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Land:	1
Commonwealth Heritage Places:	None
Listed Marine Species:	103
Whales and Other Cetaceans:	12
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Australian Marine Parks:	None

Extra Information

This part of the report provides information that may also be relevant to the area you have nominated.

State and Territory Reserves:	5
Regional Forest Agreements:	None
Invasive Species:	17
Nationally Important Wetlands:	None
Key Ecological Features (Marine)	None

Details

Matters of National Environmental Significance

National Heritage Properties		[Resource Information]
Name	State	Status
Indigenous		
Dampier Archipelago (including Burrup Peninsula)	WA	Listed place

Listed Threatened Species		[Resource Information]
Name	Status	Type of Presence
Birds		
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat known to occur within area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat known to occur within area
Calidris tenuirostris Great Knot [862]	Critically Endangered	Species or species habitat known to occur within area
Charadrius leschenaultii Greater Sand Plover, Large Sand Plover [877]	Vulnerable	Species or species habitat known to occur within area
Charadrius mongolus Lesser Sand Plover, Mongolian Plover [879]	Endangered	Species or species habitat known to occur within area
Limosa lapponica baueri Bar-tailed Godwit (baueri), Western Alaskan Bar-tailed Godwit [86380]	Vulnerable	Species or species habitat known to occur within area
Limosa lapponica menzbieri Northern Siberian Bar-tailed Godwit, Bar-tailed Godwit (menzbieri) [86432]	Critically Endangered	Species or species habitat may occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat known to occur within area
Pezoporus occidentalis Night Parrot [59350]	Endangered	Species or species habitat may occur within area
Rostratula australis Australian Painted-snipe, Australian Painted Snipe [77037]	Endangered	Species or species habitat may occur within area
Sternula nereis nereis Australian Fairy Tern [82950]	Vulnerable	Breeding known to occur within area

Name	Status	Type of Presence
Mammals		
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Dasyurus hallucatus Northern Quoll, Digul [Gogo-Yimidir], Wijingadda [Dambimangari], Wiminji [Martu] [331]	Endangered	Species or species habitat known to occur within area
Macroderma gigas Ghost Bat [174]	Vulnerable	Species or species habitat likely to occur within area
Macrotis lagotis Greater Bilby [282]	Vulnerable	Species or species habitat likely to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Rhinonicteris aurantia (Pilbara form) Pilbara Leaf-nosed Bat [82790]	Vulnerable	Species or species habitat may occur within area
Reptiles		
Aipysurus apraefrontalis Short-nosed Seasnake [1115]	Critically Endangered	Species or species habitat likely to occur within area
Caretta caretta Loggerhead Turtle [1763]	Endangered	Breeding known to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Breeding known to occur within area
Ctenotus angusticeps Northwestern Coastal Ctenotus, Airlie Island Ctenotus [25937]	Vulnerable	Species or species habitat likely to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Breeding likely to occur within area
Eretmochelys imbricata Hawksbill Turtle [1766]	Vulnerable	Breeding known to occur within area
Liasis olivaceus barroni Olive Python (Pilbara subspecies) [66699]	Vulnerable	Species or species habitat known to occur within area
Natator depressus Flatback Turtle [59257]	Vulnerable	Breeding known to occur within area
Sharks		
Carcharias taurus (west coast population) Grey Nurse Shark (west coast population) [68752]	Vulnerable	Species or species habitat likely to occur within area
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat may occur within area
Pristis clavata Dwarf Sawfish, Queensland Sawfish [68447]	Vulnerable	Species or species habitat known to occur within area
Pristis zijsron Green Sawfish, Dindagubba, Narrowsnout Sawfish [68442]	Vulnerable	Species or species habitat known to occur within area
Rhincodon typus Whale Shark [66680]	Vulnerable	Species or species

Name	Status	Type of Presence
		habitat may occur within area

Listed Migratory Species [Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Migratory Marine Birds		
Anous stolidus Common Noddy [825]		Species or species habitat may occur within area
Apus pacificus Fork-tailed Swift [678]		Species or species habitat likely to occur within area
Ardenna pacifica Wedge-tailed Shearwater [84292]		Breeding known to occur within area
Calonectris leucomelas Streaked Shearwater [1077]		Species or species habitat likely to occur within area
Fregata ariel Lesser Frigatebird, Least Frigatebird [1012]		Species or species habitat known to occur within area
Hydroprogne caspia Caspian Tern [808]		Breeding known to occur within area
Macronectes giganteus Southern Giant-Petrel, Southern Giant Petrel [1060]	Endangered	Species or species habitat may occur within area
Onychoprion anaethetus Bridled Tern [82845]		Breeding known to occur within area
Sterna dougallii Roseate Tern [817]		Breeding likely to occur within area
Migratory Marine Species		
Anoxypristis cuspidata Narrow Sawfish, Knifetooth Sawfish [68448]		Species or species habitat likely to occur within area
Balaenoptera edeni Bryde's Whale [35]		Species or species habitat may occur within area
Balaenoptera musculus Blue Whale [36]	Endangered	Species or species habitat likely to occur within area
Carcharodon carcharias White Shark, Great White Shark [64470]	Vulnerable	Species or species habitat may occur within area
Caretta caretta Loggerhead Turtle [1763]	Endangered	Breeding known to occur within area
Chelonia mydas Green Turtle [1765]	Vulnerable	Breeding known to occur within area
Dermochelys coriacea Leatherback Turtle, Leathery Turtle, Luth [1768]	Endangered	Breeding likely to occur within area
Dugong dugon Dugong [28]		Species or species habitat known to occur within area
Eretmochelys imbricata Hawksbill Turtle [1766]	Vulnerable	Breeding known to occur within area

Name	Threatened	Type of Presence
Manta alfredi Reef Manta Ray, Coastal Manta Ray, Inshore Manta Ray, Prince Alfred's Ray, Resident Manta Ray [84994]		Species or species habitat known to occur within area
Manta birostris Giant Manta Ray, Chevron Manta Ray, Pacific Manta Ray, Pelagic Manta Ray, Oceanic Manta Ray [84995]		Species or species habitat likely to occur within area
Megaptera novaeangliae Humpback Whale [38]	Vulnerable	Species or species habitat known to occur within area
Natator depressus Flatback Turtle [59257]	Vulnerable	Breeding known to occur within area
Orcinus orca Killer Whale, Orca [46]		Species or species habitat may occur within area
Pristis clavata Dwarf Sawfish, Queensland Sawfish [68447]	Vulnerable	Species or species habitat known to occur within area
Pristis zijsron Green Sawfish, Dindagubba, Narrowsnout Sawfish [68442]	Vulnerable	Species or species habitat known to occur within area
Rhincodon typus Whale Shark [66680]	Vulnerable	Species or species habitat may occur within area
Sousa chinensis Indo-Pacific Humpback Dolphin [50]		Species or species habitat known to occur within area
Tursiops aduncus (Arafura/Timor Sea populations) Spotted Bottlenose Dolphin (Arafura/Timor Sea populations) [78900]		Species or species habitat known to occur within area
Migratory Terrestrial Species		
Hirundo rustica Barn Swallow [662]		Species or species habitat may occur within area
Motacilla cinerea Grey Wagtail [642]		Species or species habitat may occur within area
Motacilla flava Yellow Wagtail [644]		Species or species habitat may occur within area
Migratory Wetlands Species		
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat known to occur within area
Arenaria interpres Ruddy Turnstone [872]		Species or species habitat known to occur within area
Calidris acuminata Sharp-tailed Sandpiper [874]		Species or species habitat known to occur within area
Calidris alba Sanderling [875]		Species or species habitat known to occur within area
Calidris canutus Red Knot, Knot [855]	Endangered	Species or species habitat known to occur within area

Name	Threatened	Type of Presence
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat known to occur within area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat may occur within area
Calidris ruficollis Red-necked Stint [860]		Species or species habitat known to occur within area
Calidris subminuta Long-toed Stint [861]		Species or species habitat known to occur within area
Calidris tenuirostris Great Knot [862]	Critically Endangered	Species or species habitat known to occur within area
Charadrius leschenaultii Greater Sand Plover, Large Sand Plover [877]	Vulnerable	Species or species habitat known to occur within area
Charadrius mongolus Lesser Sand Plover, Mongolian Plover [879]	Endangered	Species or species habitat known to occur within area
Charadrius veredus Oriental Plover, Oriental Dotterel [882]		Species or species habitat known to occur within area
Glareola maldivarum Oriental Pratincole [840]		Species or species habitat known to occur within area
Limicola falcinellus Broad-billed Sandpiper [842]		Species or species habitat known to occur within area
Limosa lapponica Bar-tailed Godwit [844]		Species or species habitat known to occur within area
Limosa limosa Black-tailed Godwit [845]		Species or species habitat known to occur within area
Numenius madagascariensis Eastern Curlew, Far Eastern Curlew [847]	Critically Endangered	Species or species habitat known to occur within area
Numenius phaeopus Whimbrel [849]		Species or species habitat known to occur within area
Pandion haliaetus Osprey [952]		Breeding known to occur within area
Phalaropus lobatus Red-necked Phalarope [838]		Species or species habitat known to occur within area
Pluvialis fulva Pacific Golden Plover [25545]		Species or species habitat known to occur within area
Pluvialis squatarola Grey Plover [865]		Species or species habitat known to occur within area
Thalasseus bergii Crested Tern [83000]		Breeding known to occur

Name	Threatened	Type of Presence within area
Tringa brevipes Grey-tailed Tattler [851]		Species or species habitat known to occur within area
Tringa nebularia Common Greenshank, Greenshank [832]		Species or species habitat known to occur within area
Tringa stagnatilis Marsh Sandpiper, Little Greenshank [833]		Species or species habitat known to occur within area
Tringa totanus Common Redshank, Redshank [835]		Species or species habitat known to occur within area
Xenus cinereus Terek Sandpiper [59300]		Species or species habitat known to occur within area

Other Matters Protected by the EPBC Act

Commonwealth Land [Resource Information]

The Commonwealth area listed below may indicate the presence of Commonwealth land in this vicinity. Due to the unreliability of the data source, all proposals should be checked as to whether it impacts on a Commonwealth area, before making a definitive decision. Contact the State or Territory government land department for further information.

Invasive Species [Resource Information]

Weeds reported here are the 20 species of national significance (WoNS), along with other introduced plants that are considered by the States and Territories to pose a particularly significant threat to biodiversity. The following feral animals are reported: Goat, Red Fox, Cat, Rabbit, Pig, Water Buffalo and Cane Toad. Maps from Landscape Health Project, National Land and Water Resouces Audit, 2001.

Name	Status	Type of Presence
Birds		
Columba livia Rock Pigeon, Rock Dove, Domestic Pigeon [803]		Species or species habitat likely to occur within area
Passer domesticus House Sparrow [405]		Species or species habitat likely to occur within area

Caveat

The information presented in this report has been provided by a range of data sources as acknowledged at the end of the report.

This report is designed to assist in identifying the locations of places which may be relevant in determining obligations under the Environment Protection and Biodiversity Conservation Act 1999. It holds mapped locations of World and National Heritage properties, Wetlands of International and National Importance, Commonwealth and State/Territory reserves, listed threatened, migratory and marine species and listed threatened ecological communities. Mapping of Commonwealth land is not complete at this stage. Maps have been collated from a range of sources at various resolutions.

Not all species listed under the EPBC Act have been mapped (see below) and therefore a report is a general guide only. Where available data supports mapping, the type of presence that can be determined from the data is indicated in general terms. People using this information in making a referral may need to consider the qualifications below and may need to seek and consider other information sources.

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Threatened, migratory and marine species distributions have been derived through a variety of methods. Where distributions are well known and if time permits, maps are derived using either thematic spatial data (i.e. vegetation, soils, geology, elevation, aspect, terrain, etc) together with point locations and described habitat; or environmental modelling (MAXENT or BIOCLIM habitat modelling) using point locations and environmental data layers.

Where very little information is available for species or large number of maps are required in a short time-frame, maps are derived either from 0.04 or 0.02 decimal degree cells; by an automated process using polygon capture techniques (static two kilometre grid cells, alpha-hull and convex hull); or captured manually or by using topographic features (national park boundaries, islands, etc). In the early stages of the distribution mapping process (1999-early 2000s) distributions were defined by degree blocks, 100K or 250K map sheets to rapidly create distribution maps. More reliable distribution mapping methods are used to update these distributions as time permits.

Only selected species covered by the following provisions of the EPBC Act have been mapped:

- migratory and
- marine

The following species and ecological communities have not been mapped and do not appear in reports produced from this database:

- threatened species listed as extinct or considered as vagrants
- some species and ecological communities that have only recently been listed
- some terrestrial species that overfly the Commonwealth marine area
- migratory species that are very widespread, vagrant, or only occur in small numbers

The following groups have been mapped, but may not cover the complete distribution of the species:

- non-threatened seabirds which have only been mapped for recorded breeding sites
- seals which have only been mapped for breeding sites near the Australian continent

Such breeding sites may be important for the protection of the Commonwealth Marine environment.

Chapter 10 C.7 Species identified in PMST not considered likely to occur within Project Area

Species identified by the PMST as potentially occurring within the Project Area, but which are not considered likely to occur within the Project Area and/or be impacted by Project Activities and were, therefore, excluded from discussion. Justification of this decision is provided here.

Species	EPBC Act Listing	Status under BC Act	Justification
Birds			
***Assessment**: The following migratory shorebird species utilise sites along the WA coastline (e.g. 80 Mile Beach, Roebuck Bay and Ashmore Reef). They do not have key sites within the Project Area and are not expected to occur within the Project Area, other than as migratory vagrants.*			
Red knot (*Calidris canutus*)	Endangered, Migratory (Wetland), Marine	Endangered	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area.
Curlew sandpiper (*Calidris ferruginea*)	Critically Endangered, Migratory (Wetland), Marine	Critically Endangered	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area.
Eastern curlew (*Numenius madagascariensis*)	Critically Endangered, Migratory (Wetland), Marine	Critically Endangered	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area.
Sharp-tailed sandpiper (*Calidris acuminate*)	Migratory (Wetland), Marine	Migratory	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area.
***Assessment**: The following species do not have key sites within the Project Area, however, as these species are migratory, they may be present as vagrants within the Project Area.*			
Greater frigatebird (*Fregata minor)*	Migratory (Marine), Marine	Migratory	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area.
Pectoral sandpiper (*Calidris melanotos*)	Migratory (Wetland), Marine	Migratory	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area.
Grey wagtail (*Motacilla cinereal*)	Migratory (Terrestrial), Marine	Migratory	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area.
Yellow wagtail (*Motacilla flava*)	Migratory (Terrestrial), Marine	Migratory	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area.
Red-rumped swallow (*Cecropis daurica*)	Migratory (Terrestrial), Marine	Migratory	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area.

Species	EPBC Act Listing	Status under BC Act	Justification
Marine Mammals			
Killer whale (*Orcinus orca*)	Migratory (Marine)	N/A	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area. **Assessment:** The killer whale is the largest member of the dolphin family and is widespread from polar to equatorial regions of all oceans. This species has been recorded for waters all states of Australia (Bannister et al., 1996), with concentrations reported around Tasmania and frequent sightings in South Australia and Victoria. Killer whales appear to be more common in cold, deep waters; however, they have been observed along the continental slope and shelf (Bannister et al., 1996), as well as in shallow coastal areas of WA (RPS, 2011). Killer whales are not well surveyed in Australian waters, with the exception of the Antarctic where whale surveys have been conducted and off Macquarie Island in the southwest Pacific Ocean. There are no documented areas of aggregation or important habitat for killer whales within the Browse Development Area (including Scott Reef) or along the proposed BTL route. Given the wide distribution of killer whales, it is possible that they may occur in the Project Area while travelling within the wider NWMR. .
Pygmy killer whale (*Feresa attenuata*)	Cetacean	N/A	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area. **Assessment:** There are a limited number of recordings for this species within Australia; a number of records are in relation to strandings with three mass stranding events in and around Augusta (WA) since 1986. Records indicate this species is distributed widely throughout Australia, typically in deep offshore waters. There is no known key habitat within the Project Area for this cetacean species and it is not expected to be present in large numbers within the Project Area.
False killer whale (*Pseudorca crassidens*)	Cetacean	N/A	**SPRAT Distribution Map**: Species or species habitat *likely* to occur within Project Area. **Assessment:** The false killer whale is considered to be widespread globally in tropical and warm temperate waters,

Species	EPBC Act Listing	Status under BC Act	Justification
			including throughout Australian oceanic waters. Though sometimes sighted closer to the coast in areas with cooler water, this species is typically oceanic in distribution and sighted away from land (Australian Museum, 2019; DEC, 2011). The false killer whale is known to form groups in excess of 100 individuals with strong social cohesion (DEC, 2011). Two mass stranding events for this species have occurred in southern WA in Augusta (1986 and 1988; DEC, 2011). The false killer whale's distribution has largely been surmised from stranding events and incidental sightings. A NT study found by satellite tracking of four individuals indicated, regular use of both coastal and pelagic waters of the Arafura and Timor Seas. Globally, however, the species is listed as Data Deficient by the IUCN and no population estimates or categorised habitat preferences are available for this species. There are no known key habitats for this species within the Project Area and survey efforts to date encompassing the Project Area have recorded this species. This species is not expected to occur in large numbers within the Project Area.
Short-finned pilot whale (*Globicephala macrorhynchus*)	Cetacean	N/A	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area. **Assessment:** The short-finned pilot whale has a widespread distribution throughout Australia in tropical and warm-temperate waters. There is a paucity of records for this species within Australian waters, with limited incidental sightings and only a few stranding events around Australia to provide records of possible distribution. This species is still hunted in Japan. No key habitats have been identified within the Project Area. This species is not expected to occur in large numbers within the Project Area.
Sperm whale (*Physeter macrocephalus*)	Migratory (Marine)	Vulnerable	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area. **Assessment:** The sperm whale is the largest of the toothed whales. The species is distributed globally in deep waters off continental shelves and sometimes near

Species	EPBC Act Listing	Status under BC Act	Justification
			shelf edges (Bannister et al., 1996). Sperm whales have been recorded in all Australian state waters and are known to migrate northward in winter and southwards in summer (Bannister et al., 1996). They tend to inhabit offshore areas with a water depth greater than 600 m and are uncommon in waters less than 300 m deep (National Marine Fisheries Service, 2006). Sperm whales, like other toothed whales, live in groups of up to 50 individuals, although male sperm whales are sometimes solitary in high latitudes (above 40°). In WA sperm whales have two BIAs recognised for foraging activities; these are located west of Rottnest Island and along the southern WA coastline between Cape Leeuwin and Esperance (more than 1,000 km from the Project Area). In deep water off the North West Cape sperm whales have been sighted in pod sizes of up to six animals between February and April from two separate surveys, in 2010 and 2017 (EPI Group, 2017; RPS, 2011). Based on the available information, it is considered unlikely that the sperm whale will be present in large numbers within the project area; however, transient individuals may occur especially in the areas of greatest water depth which occur off the west side of Scott Reef in the Browse Development Area.
Pygmy sperm whale (Kogia breviceps)	Cetacean	N/A	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area. **Assessment:** This species typically occurs in warmer oceanic waters and has been recorded in all Australian States. There are no known key habitats within the Project Area. This species is, therefore, not expected to occur in large numbers within the Project Area.
Dwarf sperm whale (*Kogia simus*)	Cetacean	N/A	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area. **Assessment:** This species typically occurs in warmer oceanic waters. There are no known key habitats within the Project Area. This species is, therefore, not

Species	EPBC Act Listing	Status under BC Act	Justification
			expected to occur in large numbers within the Project Area.
Blainville's beaked whale (*Mesoplodon densirostris*	Cetacean	N/A	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area. **Assessment:** Blainville's beaked whales are considered to have an oceanic and global distribution, occurring in low to mid latitudes in all oceans and both hemispheres, and preferring tropical and warm temperate waters (Mead, 1989). There are no estimates of population size either globally or in Australia but the species appears to be one of the more widespread and common beaked whales (Pitman, 2002). Their preferred habitat appears to be in tropical oceanic regions, in waters ranging from 700 m to 100 m deep, but are often recorded adjacent to much deeper waters of 5000 m (Bannister et al., 1996). Historically it was thought that Blainville's beaked whales avoided coasts, however, a study suggested that this species are the most commonly seen beaked whales in the shallower waters around tropical oceanic islands (Culik, 2011). It is likely that such habitats are utilised by beaked whales along much of Australia's extensive coastline (Ross, 2006). There are no key habitat known within the Project Area. Given this species wide distribution it is not expected to occur in large numbers within the Project Area.
Cuvier's beaked whale (*Ziphius cavirostris*)	Cetacean	N/A	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area. **Assessment:** Cuvier's beaked whales may have the most extensive range and be one of the most abundant of any beaked whale species (Culik, 2011). The species has a worldwide distribution in all temperate and tropical waters and is only absent from the polar waters in each hemisphere. In Australian waters, Cuviers beaked whale is known from 31 strandings, mostly from January to July, suggesting some seasonality to occurrence (Ross, 2006). Records of this species are from all States and Territories. Whaling records from Japan indicate that Cuvier's beaked

Species	EPBC Act Listing	Status under BC Act	Justification
			whales are most commonly found in waters deeper than 1,000 m. They are considered an oceanic species and are rarely found close to mainland shores, except in submarine canyons or in areas where the continental shelf is narrow and coastal waters are deep. Similar to the Blainville's beaked whale this species may utilise shelf-edge habitats along much of Australia's extensive coastline. There are no known key habitat within Australian waters and the species is not expected to occur in large numbers within the Project Area.
Melon-headed whale (*Peponocephala electra*)	Cetacean	N/A	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area. **Assessment:** Records for this species are largely from mass stranding events in the NT, NSW and QLD. There are no known key habitat within the Project Area for this species and it is not expected to occur within the Project Area.
Australian snubfin dolphin (*Orcaella heinsohni*)	Migratory (Marine)	Priority 4	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area. **Assessment:** This species occurs along the Australian coastline, typically in shallow waters, including north of Broome within WA. No key habitat have been identified within or in proximity to the Project Area and this species is not expected to occur within the Project Area.
Irrawaddy dolphin (*Orcaella brevirostris*)	Cetacean, Migratory (Marine)	N/A	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area. **Assessment:** This species is known to occur north of Broome within WA, typically in shallow coastal waters. There are no known key habitat within the Project Area. The species, is therefore, not expected to occur in large numbers within the Project Area.
Striped dolphin (*Stenella coeruleoalba*)	Cetacean	N/A	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area. **Assessment**: There is a sparsity of records within Australia and the species is not thought to be common in Australian waters. There are no known key habitat within the Project Area and the species is

Species	EPBC Act Listing	Status under BC Act	Justification
			not expected to occur within the Project Area.
Rough-toothed dolphin (*Steno bredanensis*)	Cetacean	N/A	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area. **Assessment**: Within WA this species was recorded at Barrow Island, south of the Project Area, when three individuals were stranded in 1971. There are no known key habitat within the Project Area or in WA waters. The species is not expected to occur in large numbers within the Project Area.
Bottlenose dolphin (*Tursiops truncatus*)	Cetacean	N/A	**SPRAT Distribution Map**: Species or species habitat *likely* to occur within Project Area. **Assessment:** This species is distributed widely throughout offshore, coastal and estuarine waters in Australia. There are no known key habitat within the Project Area, however, due to its wide distribution it may occur within the Project Area.
Spotted bottlenose dolphin (Arafura/Timor Sea populations) *(Tursiops aduncus - Arafura/Timor Sea populations)*	Cetacean, Migratory (Marine)	N/A	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area. **Assessment**: This species distribution extends south from the Timor and Arafura Seas to approximately Coral Bay (WA). It inhabits both inshore and offshore habitats and may occur within the Project Area.
Spotted Bottlenose Dolphin (*Tursiops aduncus*)	Cetacean	N/A	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area. **Assessment**: This species is widely distributed throughout Australian waters, with a preference for nearshore habitats. Due to its widespread distribution it may occur within the Project Area.
Oceanic Dolphin Species *Assessment: There is a paucity of records for these oceanic dolphin species, largely due to their offshore existence, meaning that population numbers, seasonal behaviours/movements (if any) and key habitat of aggregation/importance are unknown. Distribution within Australia is largely ascertained from incidental sightings and/or stranding events.* *As these species do not have key habitats identified within WA waters, and as they are described as having widespread distributions, large numbers of these species are not expected to occur within the Project Area; rather, only low numbers of individuals may transit the area. Additional species specific information is provided below.*			

Species	EPBC Act Listing	Status under BC Act	Justification
Common dolphin (*Delphinus delphis*)	Cetacean	N/A	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area. **Assessment**: This species typically occurs in the offshore waters of all Australian States and Territories. There are two primary groupings of this species; in the southern south-eastern Indian Ocean and the Tasman Sea. These locations are a significant distance from the Project Area. There are no known key habitats within the Project Area and this species is not expected to occur within the Project Area.
Risso's dolphin (*Grampus griseus*)	Cetacean	N/A	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area. **Assessment:** Typically considered to occur in oceanic waters, although in shore sightings recorded. The species has a widespread distribution throughout Australia, although there is a paucity of records meaning that estimates of population numbers is not possible. Records of incidental sightings vary in water depths from 180 to 1,500 m. The only residential population thought to be at Fraser Island (Qld). No key habitat have been identified within the Project Area. Therefore, not expected to occur in large numbers within the Project Area.
Fraser's dolphin (*Lagenodelphis hosei*)	Cetacean	N/A	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area. **Assessment:** Within Australia, this species is known to occur north of 30°S and in waters deeper than 1,000 m. Globally the species is considered pantropical and to occur between 30°N and 30°S, with sightings outside of these latitudes considered to be vagrants. There are no known key habitat within the Project Area. This species is not expected to occur in large numbers within the Project Area.
Spotted dolphin (*Stenella attenuate*)	Cetacean	N/A	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area. **Assessment**: Within Australian waters, this species has been recorded off the NT,

Species	EPBC Act Listing	Status under BC Act	Justification
			WA, Qld and NSW. The species typically inhabits waters of depths greater than 200 m, although it is known to occur on the continental shelf. The species is considered to be common, although there are no reliable estimates of population numbers within Australia. Globally, this species has been killed for food, bait and by tuna fishers between the 1950s and 1980s. There are no known key habitat within the Project Area. This species is, therefore, not expected to occur in large numbers within the Project Area.
Marine Reptiles			
Assessment: *The following sea snake species were recorded at Scott Reef by (URS Australia Pty Ltd, 2006b, 2007). Whilst these species were recorded within the Project Area, their preference for and reliance on shallow reef habitats makes it unlikely that they will be impacted by Project infrastructure or activities. Notably, these species are thought to be resident at Scott Reef and to not undertaken migrations to/from the reef; it is subsequently unlikely that they will interact with Project vessels in deeper waters near to the reef.*			
Horned seasnake *(Acalyptophis peronii*)	Marine	N/A	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area.
Dubois' seasnake *(Aipysurus duboisii*)	Marine	N/A	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area.
Olive seasnake (*Aipysurus laevis*)	Marine	N/A	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area.
Turtle-headed seasnake (*Emydocephalus annulatus*)	Marine	N/A	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area.
Slender-necked seasnake (*Hydrophis coggeri*)	Marine	N/A	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area.
Dusky seasnake (*Aipysurus fuscus*)	Marine	N/A	**SPRAT Distribution Map**: Species or species habitat *likely* to occur within Project Area.
Assessment: *The following sea snakes were not recorded at Scott Reef despite comprehensive survey effort by URS Australia Pty Ltd (2006b, 2007). As Scott Reef is the only shallow reef habitat within the Project Area these species are only expected to occur with the Project Area as vagrants, if at all.*			

Species	**EPBC Act Listing**	**Status under BC Act**	**Justification**
Short-nosed seasnake (*Aipysurus apraefrontalis*)	Critically Endangered, Marine	Critically Endangered	**SPRAT Distribution Map**: Species or species habitat *likely* to occur within Project Area**.**
Stokes' seasnake (*Astrotia stokesii*)	Marine	N/A	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area.
Spectacled seasnake (*Disteira kingii*)	Marine	N/A	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area.
Olive-headed seasnake (*Disteira major*)	Marine	N/A	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area.
Elegant seasnake (*Hydrophis elegans*)	Marine	N/A	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area.
Spotted seasnake (*Hydrophis ornatus*)	Marine	N/A	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area.
Spine-bellied seasnake (*Lapemis curtus*)	Marine	N/A	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area.
North-western mangrove seasnake (*Ephalophis greyi*)	Marine	N/A	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area.
Fine-spined seasnake (*Leioselasma czeblukovi*)	Marine	N/A	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area.
Small-headed seasnake (*Hydrophis macdowelli*)	Marine	N/A	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area.
Yellow-bellied seasnake (*Pelamis platurus*)	Marine	N/A	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area. **Assessment**: This species is distributed widely throughout Australian waters, typically exhibiting a preference for warmer waters. This species is known to frequent waters some kilometres from coastlines. There are no known key sites for this species within the Project Area; however given its broad distribution it may occur within the Project Area.

Species	EPBC Act Listing	Status under BC Act	Justification
Fish			
White shark (*Carcharodon carcharias*)	Vulnerable, Migratory (Marine)	Vulnerable	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area. **Assessment**: This species is widely distributed in Australian waters and, therefore, may occur within the Project Area. There are no known key sites for this species within the Project Area and the species is not expected to interact with the Project infrastructure or activities.
Northern river shark (*Glyphis garricki*)	Endangered	Priority 1	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area. **Assessment**: Distributed across the northern WA and NT coastal areas, this species lives between both freshwater and seawater habitats, particularly rivers, intertidal and inshore habitats and estuarine systems. The species has also been recorded in waters further offshore, however, the extent to which this occurs is uncertain. Therefore, this species is not expected to occur within the Project Area.
Reef manta ray (*Mobula alfredi*)	Migratory (Marine)	N/A	**SPRAT Distribution Map**: Species or species habitat *likely* to occur within Project Area. **Assessment**: This species may occur in low numbers within the Project Area and is not expected to interact with Project vessels or infrastructure. There are no known key sites for this species within the Project Area.
Giant manta ray (*Mobula birostris*)	Migratory (Marine)	N/A	**SPRAT Distribution Map**: Species or species habitat *likely* to occur within Project Area. **Assessment**: This species may occur in low numbers within the Project Area and is not expected to interact with Project vessels or infrastructure. There are no known key sites for this species within the Project Area.
Narrow sawfish (*Anoxypristis cuspidate*)	Migratory (Marine)	N/A	**SPRAT Distribution Map**: Species or species habitat *may* occur within Project Area. **Assessment**: This species is not expected to occur within the Project Area due to the species' preference for shallow coastal habitats.

1 Introduction

In September 2018, the BJV selected the Browse to North West Shelf (NWS) development concept to progress into the concept definition phase.

Woodside Energy Limited (Woodside) has contracted Neptune Geomatics Pty Ltd (Neptune) to undertake two phases for the Browse to NWS Project.

The Browse to NWS Project is required to confirm a nominal pipeline route corridor is suitable and collect detailed data for engineering design purposes. The MV Outer Limit (Outer Limit) is the dedicated vessel for the Neptune scope of work, supplied by Offshore Unlimited.

The Browse to NWS Project comprises two field work phases, each containing discrete work packages, being:

1. Reconnaissance Phase:
   - Work Package 1 – Reconnaissance Survey.
2. Primary Survey Phase:
   - Work Package 3 – Geophysical Survey
   - Work Package 4 – Geotechnical Investigation
   - Work Package 5 – Environment Survey.

1.1 Survey Objectives

Neptune has engaged Advisian to support the delivery of Work Package 5 – Environment Survey. This report presents the results of the Environment Survey, including benthic habitat map validation (seabed imagery), sediment quality and water column physico-chemical properties. The objectives of the Environmental Survey were to survey strategically identified locations along the proposed Browse Trunkline (BTL) route, including areas where the BTL would intersect with Key Ecological Features (KEFs) and Australian Marine Parks (AMPs) to:

- confirm the environmental characteristics (physical and biological attributes) of habitat types selected from the geophysical data, including identification and semi qualitative descriptions of seabed habitat types and their general distribution (plus documentation of sensitive receptor types, if encountered)
- collect and record baseline water and seabed samples to present the physico-chemical characteristics and quality.

2 Survey Design and Sampling Rationale

2.1 Review of Existing Data

Advisian evaluated the supplied bathymetry and backscatter data acquired during Work Package 1 (Neptune, 2018) to identify areas of potential interest, including areas that demonstrate high reflectivity associated with harder substrates. Swath bathymetry was acquired between 28 October 2018 and 16 November 2018 using a Kongsberg EM710 Multibeam Echo Sounder (MBES). Data logged by Kongsberg SIS was imported to CARIS HIPS, where it was examined, processed and reduced to final soundings. In addition, seabed intensity data (backscatter) was processed within HIPS. Surfaces were created from the final soundings and exported to ESRI ASCII format, while backscatter data was exported to GeoTIFF format. The geophysical data was interpreted based on a visual assessment of the geomorphic features on the seabed, using the bathymetry and backscatter data collected during the geophysical survey.

A preliminary seabed habitat map was produced based on the interpretation of the MBES and a standardised classification scheme for substrate and features, which was the Collaborative and Annotation Tools for Analysis of Marine Imagery and Video (CATAMI) (Table 2-1). Each standardised label was also assigned a CAAB (Codes for Australian Aquatic Biota) 'code' (Table 2-2).

The preliminary seabed habitat map (Appendix A) was used as the basis to strategically identify survey locations overlaid with the intersection of the BTL route with AMPs and KEFs.

Table 2-1: Attribute table (final substrate descriptor using CATAMI classification)

Descriptor	Bathymetry	Slope/Topographic Position	Relative Backscatter
Find sand/mud	Smooth (no discernible features beyond acquisition artefacts at 5 m gridding), or with identifiable, regular ripples or dunes	Even, typically less than 5°	Low (dark); no discernible features at 1 m gridding
Coarse (sand-gravel)	Smooth (no discernible features beyond acquisition artefacts at 5 m gridding), or with identifiable, regular ripples or dunes	Even, typically less than 5°	High (light); no discernible features at 1 m gridding
Rock veneer	Uneven, rugged and irregular features	Variable, typically less than 5°, topographic high	Varied; mostly high
Rock veneer (superimposed ripples)	Uneven, rugged and irregular features. Various irregular ripple or dune types may be present	Variable, typically less than 5°	Varied, mostly high; finer scale ripple/dune features may be evident
Isolated dune (e.g. ribbon, stringers)	Bathymetric feature, smooth	Variable, may have steep sides	Varies depending on incidence angle
Sloped Terrain (Scarp, Scour)	Bathymetric feature, smooth	Typically greater than 5°, may have steep sides	Varies depending on incidence angle
Ripples (Small, Medium 2D or 3D, Irregular)	May be visible bathymetric features, or may only occur in backscatter if small	Varied, wavelength and amplitude measured in profile (Ashley, 1990)	Varies depending on incidence angle; typically low
Waves (Medium, Large, Very Large 2D or 3D, Irregular)	Bathymetric features measurable in profile	Varied, wavelength and amplitude measured in profile (Ashley, 1990)	Varies depending on incidence angle
Mound (Rock or Rock Veneer)	Bathymetric features measurable in profile; isolated, sharp edged feature	Varied, up to 90°	Varies depending on incidence angle; typically very high
Depression (Scour or Pockmark)	Bathymetric features measurable in profile	Varied, up to 90°	Varies depending on incidence angle

Table 2-2: Classification table – feature descriptors (using the decision tree)

S1	S2	S3	R1	R2	B1	B2	B3
Consolidated/ Hard (CAAB 82 001001)	**Fine sand/ mud** (CAAB 82 001015 + 82 001016 Undiff.)	**Veneer**	**Flat** (CAAB 82 003001)	**Low** <1 m (CAAB 82 003003)	**None** (CAAB 82 002001)	**Ripples** <10 cm (CAAB 82 002003)	<10 m **Small***
Unconsolidated/ Soft (CAAB 82 001005)	**Coarse sand** (CAAB 82 001014)	**Rock** (CAAB 82 001002)	**Low/ Mod** (CAAB 82 003002)	**Mod** 1 to 3 m (CAAB 82 003004)	**2D** (CAAB 82 002002)	**Waves** >10 cm (CAAB 82 002004)	10-50 m **Med***
	Pebble/ gravel (CAAB 82 001006)		**High** (CAAB 82 003005)	**HIGH** >3 m (CAAB 82 003006)	**3D** (CAAB 82 002006)	**Large Waves*** >0.75 m	50-100 m **Large***
				Wall (CAAB 82 003007)	**Other**	**Very Large Waves*** >5 m	>100 m **Very Large***
						Irregular*	

Derived from Ashley, 1990.

2.2 Sampling Rationale

The sampling rationale was agreed in a Sampling and Analysis Plan (SAP) (Advisian, 2019) prior to survey mobilisation and is summarised in this section.

Sampling sites were selected to provide data to document the existing environment of the proposed BTL (Table 2-4), including habitat types and features across the depth profile and geographical coverage of the BTL route, using the preliminary habitat map (Appendix A) as a basis to determine an appropriate sampling approach.

The proposed BTL route options include passage through designated areas described in Table 2-3. These designated areas were overlaid on the geophysical data and a range of substrata and seabed bedforms selected within each area (Table 2-4). Areas of sparse data and spatial coverage of the BTL route were also considered to design the survey and select sampling sites.

Additional rationale for selecting sampling sites is provided in Appendix B. The sample sites relative to the KEFs and AMPs are presented in Figure 2-1 and Figure 2-2.

Table 2-3: Environmental and conservation values of AMPs and KEFs that intersect the proposed pipeline route

Area of Environmental Importance	Environmental Values
Argo-Rowley Terrace (Multiple Use Zone, IUCN VI)	Marine Park provides protection for the communities and habitats of the deeper offshore waters of the region in depth ranges from 22 to 5000 m. Marine Park provides connectivity between the Mermaid Reef Marine Park/WA Rowley Shoals Marine Park and the deeper waters of the region. Adjacent to important foraging and pupping areas for sawfish and important nesting sites for green turtles (Director of National Parks, 2018).
Kimberley Marine Parks (Multiple Use Zone, IUCN VI)	Marine Park provides protection for the communities and habitats of waters offshore of the Kimberley coastline ranging in depth from less than 15 to 800 m. Important foraging areas for migratory seabirds, migratory dugongs, dolphins and threatened and migratory marine turtles. Important migration pathway and nursery areas for the protected humpback whale (Director of National Parks, 2018).
Continental Slope Demersal Fish Communities KEF	This KEF represents the diversity of demersal fish assemblages on the continental slope in the Timor Province, the North-west Transition and the North-west Province which is high compared to elsewhere along the continental slope (Commonwealth of Australia, 2012).
Ancient Coastline at 125 m Depth Contour KEF	Parts of the ancient coastline, particularly where it exists as a rocky escarpment, are thought to provide biologically important habitats in areas otherwise dominated by soft sediments (Commonwealth of Australia, 2012).
Mermaid Reef and Commonwealth waters surrounding Rowley Shoals KEF	Mermaid Reef and the Commonwealth waters surrounding the Rowley Shoals are recognised as areas of enhanced productivity and high species richness, facilitated by the breaking of internal waves in the waters surrounding the reefs. This results in the mixing and re-suspension of nutrients from water depths of 500 to 700 m into the photic zone. Migratory pelagic species are present due to the steep changes in slope, such as dolphins, tuna, billfish and sharks (Commonwealth of Australia, 2012).
Seringapatam Reef and Commonwealth waters in the Scott Reef Complex KEF	Seringapatam Reef and the Commonwealth waters in the Scott Reef complex are regionally important as they support diverse aggregations of marine life, high primary productivity and high species richness (Commonwealth of Australia, 2012).

19	120	Ancient Coastline at 125 m Depth Contour KEF	Fine sand-mud	Y	Y	Y

3 Sampling Methodology

3.1 Survey Timing

The survey was completed between 9 March and 10 June 2019. Over this period, the survey vessel was required to seek safe anchorage on a number of occasions to avoid adverse weather, including during the passage of Tropical Cyclone Veronica in late March. Survey events are summarised in Appendix C.

3.2 Benthic Habitat (Seabed Imagery)

3.2.1 Camera System

Seabed imagery was captured using the STR Sea Spyder Drop Camera System, capable of working at depths of up to 1000 m. The system was configured and integrated to the survey vessel during project mobilisation, before leaving the port.

The camera system provided live standard definition footage to the surface, allowing the operator to view the seabed footage in real time. The lighting and flash system were aligned to provide clear video and digital stills. A high-resolution digital camera was used to capture still images of the seabed and any benthic communities of interest. Additionally, an autonomous high definition video camera was mounted to the frame to collect high definition video. A scaling laser system was also configured with the camera spread to ensure it was visible in the telemetered video footage and still images.

Geographical positioning data was recorded using an Ultra-Short Base Line (USBL) system, with a beacon mounted above the camera frame. Time stamps on all cameras were synced with the timing on the USBL system, ensuring all footage was georeferenced. The positioning system and data management was supplied and operated by Neptune.

3.2.2 Survey Methodology

At each site, the camera was lowered to about 1 m above the seabed. Camera heights were controlled from the coaxial winch. Typically, the camera would be landed on the seafloor to obtain clear images and then raised about 1 m while the vessel drifted or motored a short distance away (less than 20 m) to increase spatial coverage. Once camera movement stabilised, the camera was lowered back to the seafloor and additional images were collected. Spatial coverage depended on several factors including the rate of drift, subsea currents and surface wave action (heave). A minimum of ten minutes of video footage was collected at each site.

3.2.3 Image Assessment

Video footage was described in seabed logs onboard the vessel and qualitatively classified using the CATAMI classification scheme. All footage was reviewed upon completing the survey and benthic classifications were checked. Broader scale seabed features (large sand waves, isolated mounds) were hard to identify from the seabed imagery, given the limited field of view of the drop camera system. Discrepancies between the preliminary habitat map and the observed seabed features may result from these scale differences. For example, seabed imagery may be classified as 2D ripples but these may be superimposed on the surface of larger sandwave features.

3.3 Water Quality

The water column along the BTL was characterised by implementing the following methods.

3.3.1 Water Profiling

Baseline water quality data was collected over the entire water column at each site. Vertical profiles to full ocean depth were taken using a calibrated Seabird Electronics (SBE) 19plus current, temperature and depth profiler (CTD) with integrated WET Labs fluorometers to measure turbidity. Data was logged while deploying and retrieving the CTD.

The SBE 19plus CTD profiler was equipped with sensors to measure:

- depth (pressure)
- conductivity
- temperature
- pH
- dissolved oxygen (DO)
- turbidity
- fluorescence.

3.3.2 Water Quality Sampling

Water quality samples were collected at three depths:

1. from near sea-bed
2. mid water column
3. sub-surface.

Water quality sampling was completed by lowering Niskin bottles to the designated depths where they were triggered for collection. Once retrieved on deck, the water collections were transferred into labelled sample bottles for the required analyses. Water samples were collected concurrently with the CTD deployments. Water samples were analysed for:

- Nutrients (TN, TP)
- Ammonia (NH4)
- Nitrate and Nitrite (NO_3/NO_2)
- Total Recoverable Hydrocarbons (TRH)
- Polycyclic Aromatic Hydrocarbons (PAH) (only tested for when TRH were above detection limits)
- Trace Metals (Al, As, Ba, Cd, Cr, Cu, Co, Fe, Hg, Ni, Pb, Sn, V, Zn).

3.3.3 Laboratory Analysis

Water quality was analysed at ALS, a National Association of Testing Authorities (NATA[1]) accredited laboratory. ALS analysed the required laboratory blanks and duplicates and tested standards and splits in accordance with NATA requirements.

The laboratory methods and analytical limits of reporting (LoRs) for the required water quality analysis is summarised in Table 3-1.

Table 3-1: Water quality analysis methodology and limits of reporting

Parameter	Method Reference	LoR (µg/L) (or as indicated)
TRH/BTEX/PAH	GC/FID, P&T/HS/MS GC/MS – SIM	TRH: 20 to 100 µg/L BTEX: 1 to 5 µg/L PAH: 0.5 to 2 µg/L
TRH (C11-C40), PAHs- only where TRH is detected	GC/FID, P&T/HS/MS GC/MS – SIM	TPH:20 to 100 µg/L BTEX:1 to 5 µg/L PAH: 0.5 to 2 µg/L
Ultra trace metals (Al, As, Ba, Be, Cd, Co, Cu, Fe, Pb, Hg, Mn, Ni, Ag, Sb, Sn and Zn)	APHA 3125B ORC/ICP/MS	0.00002 to 0.005
Ammonium calculated from ammonia (saline water method), temperature and pH	APHA 4500-NH3 G	0.005 mg/L
Ultra trace Nitrite and Nitrate	APHA 4500-NO3 I, APHA 4500-NO2 B	0.002 mg/L
Ultra trace Nitrogen (Total) and Phosphorus (Total)	APHA 4500-P J	0.005 to 0.050 mg/L

3.4 Sediment Quality

Baseline sediment quality was analysed to provide information on seabed particle size and to determine ambient concentrations of metals and hydrocarbons in the seabed sediments. The box corer (0.5 m × 0.5 m × 0.5 m) was constructed of stainless steel to prevent sample contamination and was supplied and operated by Neptune. Samples were photographed and processed directly on recovery. Sediment samples retained for quality analysis were handled in accordance with standard sampling protocols as required by NATA-accredited laboratories. Sample transport to the laboratories was documented under the appropriate chain of custody (CoC) documentation.

---

[1] The National Association of Testing Authorities, Australia (NATA) is Australia's national accreditation body for the accreditation of laboratories, inspection bodies, calibration services, producers of certified reference materials and proficiency testing scheme providers throughout Australia.

Sediment samples were analysed for:

- Trace Metals (Al, Ba, Cd, Cr, Cu, Fe, Hg, Ni, Pb, Sn, V, Zn)
- Organics (BTEX, TPH and PAH)
- Nutrients – Nitrate and Nitrite (NO3/NO2)
- Total Organic Carbon (TOC)
- Total Carbon (as a proportion of calcium carbonate)
- Particle Size Distribution (PSD).

3.4.1 Laboratory Analysis

All sediment quality was tested at ALS, a NATA-accredited laboratory. ALS analysed the required laboratory blanks and duplicates and tested standards and splits in accordance with NATA requirements.

The laboratory methods and analytical LoRs for the required sediment quality analysis are summarised in Table 3-2.

Table 3-2: Sediment quality analysis methodology and limits of reporting

Parameter	Method Reference	LoR (mg/kg) (or as indicated)
PSD	AS 1289 3.6.3-2003, AS 1289.3.5.1-2006	1 %
TPH	USEPA 8260B/8270D	3-5
PAHs	USEPA 8270	0.004 to 0.005
BTEX (Benzene, Toluene, Ethyl Benzene and Xylenes)	USEPA 8260B	BTEX: 0.2 to 0.5
TOC	ALs-In-house	0.02%
TC	ALS-in house	0.02%
Mercury: Total-Low level	APHA 3112 Hg-B	0.01
Trace metals: Al, Cd, Cr, Cu, Ni, Pb, V, Zn	USEPA 6020	0.1 to 2
Total Metals in Sediments: Fe, Al	USEPA 6010	50
Metals ICPMS: Ba, Sn (includes digestion)	USEPA 6020 ICP/MS	0.1
Ammonia, Nitrate, Nitrite, NOx, TKN, Total Nitrogen, Total Phosphorus	APHA 4500-NH3 B/G/H, APHA 4500-NO3 F, Thermo Scientific Method D08727 and NEMI (National Environmental Method Index) Method ID: 9171, APHA 4500-NO3 B, APHA 4500-Norg D, APHA 4500-Norg/NO3, APHA 4500-P B&H	0.1 to 20 mg/kg

3.5 Benthic Infauna

3.5.1 Sampling Sites and Characteristics

Benthic infauna sampling was attempted at 20 sampling sites as shown Figure 2-1 and Figure 2-2.

Samples could not be obtained for various reasons from three sites; Site 4, Site 9 and Site 11. At Site 15, only shell material (but no soft sediment) was obtained, likely due to consolidated substrate in this area. This shell material was sent for infauna analysis.

Field sheets were completed onsite providing the following information; date, time, location, sample ID, latitude/longitude, water depth, sample collector, type of sample, sea state, conditions (weather, sea state, wind speed, shipping traffic), sediment description and any other general comments. These are included in Appendix D.

Sampling sites were characterised in relation to their depth, sediment particle size distribution (PSD) (with no PSD data available for Site 15) and location in relation to designated areas (i.e. whether they occurred within an Australian Marine Park (and Marine Park Zone if so) or an area identified as a Key Ecological Feature (KEF)). Sediment PSD, Marine Park, Marine Park Zone and Key Ecological Features (KEFs) were all included as factors within the ensuing multivariate analysis (refer to Section 2.6).

A summary of all infauna sampling site characteristics are shown in Table 3-3.

Table 3-3 Infauna sampling site characteristics

Site	Sample Volume (L)*	Depth (m)	Sediment PSD	Marine Park	Marine Park Zone	Key Ecological Features (KEFs)
0	60	376	Refer to PSD data	Kimberly Marine Park	Multiple Use	Continental Slope Demersal Fish KEF
1	36	346	Refer to PSD data	Kimberly Marine Park	Multiple Use	Continental Slope Demersal Fish KEF

19	32.5	125	Refer to PSD data	No	No	Ancient Coastline at 125m KEF

* the sample volume (L) refers to the total volume of material collected at each site for the infauna analysis, as provided in field data sheets – the original sample volume in L was later standardised to 0.1m3 for each site for statistical analysis.

3.5.2 Sample Collection and Processing

Benthic infauna samples were collected using the same box corer (0.5 m × 0.5 m × 0.5 m = 0.125 m^3) as was used for the sediment collection and followed the method of sampling outlined for marine sediments (Section 3.4). The sediment sample used for benthic infauna analysis comprised the sediment which remained after the required volume had been taken for all other sediment characterisation analysis.

Once retrieved and on the boat, each sediment sample was sieved using an Endecott sieve with a

1 mm mesh size. After sieving the sediment, the remaining contents were transferred into buckets and samples were preserved in a ~10% borax buffered formalin solution.

Total sample volume (i.e. the volume of material sieved) varied significantly between sites, ranging from 32.5 L – 121 L. This was dependent on the total volume of material obtained from each site, the amount of sample required for sediment characteristation and operational restrictions during sampling (e.g. time available). Varying numbers of buckets were submitted to the laboratory for each site dependent on the sample volume, with this data subsequently combined for each individual site.

3.5.3 Sample Transport

Sample transport to the analytical laboratory was documented under the appropriate chain of custody (CoC) protocols.

3.5.4 Infauna Identification

All samples were identified by Aquen (Aquatic and Environmental Consulting) to family level. This level of identification has been proven to be adequate in determining the effects of anthropogenic influences on the marine environment, in particular, for infauna communities (e.g. Warwick, 1988, Chapman 1998, Underwood et al. 2003).

3.5.5 Data Analysis

3.5.5.1 Data Investigation

The total abundance of each infauna taxa (family level) identified was recorded for each site. As the original pre-sieve sample volume was not consistent between sites, the original infauna abundance data for each site was standardised to a sample volume of 0.1 m3 (100 L). Standardisation of infauna abundance data was necessary to allow for meaningful comparisons of data between sites. Richness data (i.e. the number of different taxa in a sample) was not standardised to 0.1 m3 as it is not possible to allude to the existence of additional taxa and so richness values for each site remained unchanged. The raw and standardised abundance data are provided in Appendix E.

Abundance, Richness and Diversity

Infauna abundance, richness and diversity were calculated for each site based on the standardised infauna abundance data.

A brief definition of each of these indices is provided below:

- Abundance: Relates to how common or rare taxa are relative to other taxa in a defined location or community. For the purposes of this report, total abundance = the total number of individuals at a given site.
- Richness: A measure related to the total number of different taxa present within a sample (for the purposes of this report taxa richness was determined for each site).
- Diversity: Diversity accounts for the number of taxa and the evenness of taxa, giving a measure of the biodiversity and complexity of a population. Taxa diversity consists of two components, taxa richness and taxa evenness. Taxa richness is a simple count of taxa, whereas taxa evenness quantifies how equal the abundances of the taxa are. The Shannon diversity index was used as the measure of diversity.

Family level abundance, taxa richness and Shannon diversity for each site were tabulated and presented graphically to compare these indices between sites.

The abundance and richness of all infauna Phylum identified in this study (for all sites combined) were also tabulated and presented graphically.

3.5.5.2 Multivariate Analysis

Multivariate analysis was undertaken to determine whether there were any differences in infauna assemblages between sites and whether these could be related to Factors such as depth, PSD or location within a designated area (MPA or KEF). All multivariate analyses were undertaken in PRIMER 7 with the PERMANOVA add on (Anderson et al. 2008).

3.5.5.3 Data Transformation

For multivariate analyses, the data first needed to be transformed to achieve similar distribution among datasets. The infauna abundance dataset was transformed using a square root transformation which is typical for this type of biological data and useful for low values of ecological abundance data.

3.5.5.4 Shade Plots

Shade plots were used as an alternative visual tool to assess the relative abundance of infauna families by site. These plots provided clear visual representation of the different families occurring at each site and their relative abundance as indicated by varying degrees of shading.

3.5.5.5 Resemblance Matrix

The transformed dataset was then used to make a resemblance matrix using the Bray Curtis similarity metric, which is robust to ecological data measured on different scales and with a high proportion of 'low' or absent species. A resemblance matrix is a matrix of scores which represents the similarity between each pairwise comparison of data points.

3.5.5.6 Multidimensional Scaling

The resemblance matrix was used to generate multi-dimensional scaling (MDS) plots. MDS plots are visual representations of the similarity matrix; where points that are closer together on the plot are more like each other than those further apart. Goodness of fit (stress) was assessed using Kruskal's stress formula and compared to maximum values (stress should be less than 0.2) as recommended by Sturrock and Rocha (2000).

MDS plots can be overlaid by different Factors, whereby the points on the graph which represent the similarity matrix are in the same position but are coloured according to the different Factors. The various Factors of interest which were overlaid on the MDS plots to further investigate any patterns seen included:

- Site: 0 - 19 (site 15 was excluded from multivariate analysis as no infauna were recorded).
- Depth: Depths from 100 m – 450 m were divided into 50 m class categories for categorical comparison.
- Marine Park: Kimberly Marine Park, Argo-Rowley Terrace Marine Park or N/A.
- Marine Park Zone: Multiple Use or N/A.

- Key Ecological Features: Continental Slope Demersal Fish KEF, Mermaid Reef KEF, Ancient Coastline at 125m KEF or N/A.
- Sediment Particle Size: i.e. Percentage Clay (<2 µm), Percentage Silt (2-60 µm) and Percentage Cobbles (>6 cm). This was undertaken as infauna assemblages can vary significantly with varying sediment particle sizes. MDS plots need to be grouped by categorical factors. As sediment size is continuous data, the percentage of various sediment classes were divided into 5% class categories to allow comparison by MDS.

3.6 Quality Control

3.6.1 Field QA/QC

The following quality assurance/control (QA/QC) measures were implemented during sampling:

- Sample containers were sourced from the laboratory.
- Prior to use, any evidence of or sources of contamination was cleaned or either removed from the vessel or covered to prevent contamination.
- Disposable, powder-free gloves were used for handling samples and changed after each sample.
- Equipment was decontaminated between collecting each sample.
- Field duplicates for water and sediment samples were obtained at 10% of sites (two sites).
- Field replicates for water and sediment samples were obtained at 10% of sites (two sites).

CoC forms accompanied samples and each stage of handling was recorded. The following actions were performed daily to minimise the chance of missing or misplacing a subsample:

- All pre-labelled sample containers were filled at each site.
- A sample matrix record was updated with confirmation of sites visited, and containers filled as samples were being collected.
- During each shift, the notes on the sample matrix, field book and photographs were compared against the total number of containers stored from that shift before populating the CoC form.

3.6.2 Sub Sampling

Water and sediment were sampled at a location on the vessel deck that was free from potential contamination. All sub sampling was completed in a clean area, away from any exhaust fumes or discharge locations.

Upon recovery, samples were directly subsampled or placed into the relevant sample containers or a designated and decontaminated intermediate container before further processing (e.g. filtration).

3.6.3 Sample Containers

ALS provided sampling containers and information relating to holding times and on-board storage requirements to ensure adequate sample volumes were collected.

3.6.4 Sample Naming Conventions

Each sample had a unique reference code. The reference code was used on sample labels, reports and CoC documentation. The sample reference code was written on the labels of each sample using permanent marker. Also noted were the:

- project number
- date and time
- name or initial of the person conducting the sampling.

Containers were pre-labelled where possible before commencing sampling.

3.6.5 Sample Storage and Preservation Requirements

Water and sediment quality samples designated for laboratory analysis were collected in cleaned and decontaminated laboratory-supplied glass jars. Glass containers were filled completely with sample.

Samples that required chilling or freezing were refrigerated while onboard the vessel in a designated refrigerator/freezer. Once back at port, samples were packed in sealed plastic coolers (eskies) with ice bricks before being hand carried off the vessel to transport vehicles.

3.6.6 Laboratory QA/QC

The integrity of the samples was assured using CoC documentation. Samples were always chilled using ice blocks and refrigerated between field collection and delivery to the laboratory.

As part of NATA requirements, laboratory analysis included quality control of samples, including duplicate samples (the same sample analysed more than once), blanks (containing no levels of the analytes to be analysed) and spiked samples (containing known additions of the analytes to appropriate matrices). The laboratory QA/QC report is also presented with the laboratory results in Appendix F. Field QA/QC checks are presented in Appendix G and Appendix H.

4 Results

4.1 Benthic Habitat Assessment (Seabed Imagery)

Seabed imagery was collected at all 20 sampling sites, with depths ranging from 119 to 432 m, identified in the SAP (Advisian, 2019). Substrates described at these sites were typically aligned with the preliminary habitat map (Appendix A), developed from the geophysical data. Variations between the preliminary habitat map and field data are likely a result of scale differences. Larger seabed bedforms are unlikely to be distinguished from the seabed imagery, given the field of view of the camera system. For example, ripples or waves may be identified from the camera footage; however, the identified waves/ripples may be superimposed on larger bedforms such as sand waves.

Seabed imagery was collected over a duration of approximately 10 minutes at each site, during this time the vessel remained generally static to provide a stable and safe platform for operation of the drop camera system. Resulting spatial coverage of the habitat observed in the imagery is therefore limited, and interpolation of the presence of epifauna from the geophysical data is also not possible as the approach was intended to capture data on bedform and substrate over a large area. There is no evidence to suggest that the habitat observed in the imagery is not homogenous as no boundaries were observed in the imagery and the boundaries developed in the preliminary habitat map are considered reliable (Appendix A). Confirmation of substrates defined in the preliminary habitat map can allow some inferences to the presence of epifauna beyond the scale of seabed image acquisition though this would be assumed and should be considered with caution without additional ground truthing data. Benthic habitat observed in seabed imagery did not appear to have any association with depth, nor were there discernible associations between designated management zones (AMPs or KEFs) and habitats observed.

Habitat types were relatively homogenous at each sampling site and typically consisted of Sandy seabed sediments with varying proportions of Silt and Clay, except for Site 15, which consisted of consolidated rubble. Bioturbation (disturbance of sedimentary deposits by living organisms) was evident to varying degrees between sites and was a frequent observation, since the substrate at most sites was unconsolidated soft sand or mud. Where epifauna (fauna that inhabit the seabed) was observed, it was in very low abundance, usually occurring as solitary individuals including crustaceans, various cnidarians (solitary anemones and hydroids), echinoderms (sea stars and brittle stars) and small bony fishes. Table 4-1 presents a summary of seabed imagery observations, habitat classifications and example images from each site. Photo plates, which present additional representative seabed images, are presented in Appendix I. Qualitative benthic habitat classifications are presented in Appendix J.

Table 4-1: Seabed imagery observations and summary of habitat classifications

Site Number	Approximate Depth (m)	AMP/KEF	Classification from Preliminary Habitat Map	Observed Habitat	General Comments	Example Images (laser scale = 18 cm (l) x 23 cm (h)
0	375	Kimberley Marine Park and Continental Slope Demersal Fish KEF	Coarse sand	Sediments were classified as soft fine sand/mud from the seabed imagery; the sediment sample collected at Site 0 was classified as silt with sand and clay from the PSD data. The only epibenthic fauna observed at Site 0 was a solitary prawn, though some bioturbation was evident indicating presence of some infauna.	The sediments at the sampling site were noted to be finer than predicted from the geophysical data.	1	354	Kimberley Marine Park and Continental Slope Demersal Fish KEF	Fine sand-mud	The sediments were classified as soft fine sand/mud from the seabed imagery; the sediment sample collected at Site 1 was classified as sand with some silt and clay from the PSD data. Epifauna observed in the seabed imagery were in low abundance and included a single bony fish, a lobster and solitary stalked anemone.	The habitat map is considered to accurately represent the seabed at this site.	
2	335	Continental Slope Demersal Fish KEF	Large 2D ripples	The sediments were classified as coarse sand with 3D small waves/ripples from the seabed imagery; the sediment sample collected at Site 2 was classified as sand with some silt and clay from the PSD data. Epifauna observed in the seabed imagery included occasional crabs, crinoids and solitary anemones.	There is some minor variation between the habitat map and field data in the description of the complexity of the ripples (2D.v. 3D).	3	352	Continental Slope Demersal Fish KEF	Fine sand-mud	The sediments were classified as coarse sand from the seabed imagery; the sediment sample collected at Site 3 was classified as Sand with some silt and clay from the PSD data. Epifauna observed in seabed imagery included an occasional solitary sea pen, lobster, crinoids and hydroid.	The habitat map is considered to accurately represent the seabed at this site.	

Site Number	Approximate Depth (m)	AMP/KEF	Classification from Preliminary Habitat Map	Observed Habitat	General Comments	Example Images (laser scale = 18 cm (l) x 23 cm (h)
4	350	Continental Slope Demersal Fish KEF	Fine sand-mud	The sediments were classified as soft fine Sand/Mud from the seabed imagery; the sediment sample collected at Site 4 was classified as sand with some clay from the PSD data. Very low numbers of epifauna were observed in seabed imagery and included an occasional solitary ascidian and crustacean.	The habitat map is considered to accurately represent the seabed at this site.	5	377	Continental Slope Demersal Fish KEF	Fine sand-mud	The sediments were classified as soft fine Sand/Mud from the seabed imagery; the sediment sample collected at Site 5 was classified as silt with some sand and clay from the PSD data. No evidence of benthic fauna was observed from the seabed imagery at Site 5.	The habitat map is considered to accurately represent the seabed at this site.	6	430	None	Coarse sand	The sediments were classified as coarse sand from the seabed imagery; the sediment sample collected at Site 6 was classified as sand with some clay from the PSD data. Epifauna observed in seabed imagery included a solitary crustacean (lobster) and echinoderm (sea star).	The habitat map is considered to accurately represent the seabed at this site.	
7	375	Argo-Rowley Terrace Marine Park and Mermaid Reef KEF	Medium 2D ripples	The sediments were classified as coarse sand from the seabed imagery with 3D ripples/waves; the sediment sample collected at Site 7 was classified as predominantly sand from the PSD data. Epifauna observed in seabed imagery included a solitary bony fish and echinoderm (sea star).	The habitat map is considered to accurately represent the seabed at this site.	

Site Number	Approximate Depth (m)	AMP/KEF	Classification from Preliminary Habitat Map	Observed Habitat	General Comments	Example Images (laser scale = 18 cm (l) x 23 cm (h)
8	372	Argo-Rowley Terrace Marine Park and Mermaid Reef KEF	Coarse sand	The sediments were classified as coarse sand from the seabed imagery; the sediment sample collected at Site 8 was classified as predominantly sand with some clay from the PSD data. A higher abundance of bony fishes was observed at Site 8 when compared with other sites, but there is no evidence from seabed imagery or geophysical data that the seabed habitat is significantly different from other sites or would support higher abundance of fishes compared with other sites.	The habitat map is considered to accurately represent the seabed at this site.	
9	322	Argo-Rowley Terrace Marine Park and Mermaid Reef KEF	Medium 2D sand waves	The sediments were classified as coarse Sand from the seabed imagery; the sediment sample collected at Site 9 was classified as predominantly sand from the PSD data. Epifauna observed in seabed imagery included a low abundance of crustaceans (lobsters), occurring mostly as solitary individuals.	It is hard to detect broader scale bathymetric changes from the drop camera system and the 3D ripples apparent in the seabed imagery may exist on top of larger sand wave bedforms predicted in the preliminary habitat map. The habitat map is considered to accurately represent the seabed at this site.	
10	329	Argo-Rowley Terrace Marine Park	Coarse sand	The sediments were classified as fine sand/mud from the seabed imagery; the sediment sample collected at Site 10 was classified as sand with some silt and clay from the PSD data. A higher abundance of bony fishes was observed at Site 10 when compared with other sites, but there is no evidence from seabed imagery or geophysical data that the seabed habitat is significantly different from other sites or would support higher abundance of fishes compared with other sites.	The habitat map is considered to accurately represent the seabed at this site.	

Site Number	Approximate Depth (m)	AMP/KEF	Classification from Preliminary Habitat Map	Observed Habitat	General Comments	Example Images (laser scale = 18 cm (l) x 23 cm (h)
11	260	None	Coarse sand	The sediments were classified as coarse sand from the seabed imagery; the sediment sample collected at Site 11 was classified as sand with some clay from the PSD data. Epifauna observed in seabed imagery included an occasional solitary cnidarian (sea pen/whip) and solitary bony fish, though abundance was very low.	The site site was selected as the pipeline intersects an area of potentially harder substrate with a potential for increased species richness. Evidence of harder substrate and increased species richness was not observed at this site in the imagery or PSD data. Given the preliminary classification of course sand, the habitat map is considered to accurately represent the seabed at this site.	
12	260	None	Coarse sand – some areas of softer sediments were also identified near the sampling site	The sediments were classified as fine sand/mud from the seabed imagery; the sediment sample collected at Site 12 was classified as silt with some sand and clay from the PSD data. Bioturbation at Site 12 was observed to be more prevalent, with more variation in hole size than other sites. Epifauna observed included low abundance of crustaceans (lobsters).	Imagery and PSD suggest that the sediments sampled aligned with the softer sediments indicated on the preliminary habitat map to be in the vicinity of the site and the habitat map is considered suitable at this site.	
13	260	None	Sloped terrain scarp	The sediments were classified as coarse sand from the seabed imagery; the sediment sample collected at Site 13 was classified as sand with some silt and clay from the PSD data. Epifauna observed in seabed imagery included a solitary sponge and bivalve. A small number of track marks were also observed.	The seabed at Site 13 was predicted to consist of more complex seabed features in an area of sloped terrain/scarp from the preliminary habitat map. Though no evidence of this was observed in the imagery or PSD data. Note: Broader scale geological features (greater than 10 metres) such as scarps may be difficult to detect from drop camera surveys of areas where the field of view is in the range of 1 to 10 metres.	

Site Number	Approximate Depth (m)	AMP/KEF	Classification from Preliminary Habitat Map	Observed Habitat	General Comments	Example Images (laser scale = 18 cm (l) x 23 cm (h)
14	220	None	Irregular 2D ripples	The sediments were classified as fine sand/mud from the seabed imagery; the sediment sample collected at Site 14 was classified as clay with some silt and sand from the PSD data. Sediment colour was observed to be more variable than at other sites, apparently associated with bioturbation, which was evident at Site 14.	Site 14 was selected to provide coverage of differing bedform types along the pipeline route. The seabed was relatively flat with some very small 2D ripples and notably finer sediments compared with other sections of the pipeline route. The area of irregular 2D ripples is intersected by areas of fine sand/mud on the habitat map and the habitat map is considered accurate for this site.	
15	182	None	Mound	The sediments were classified as biogenic rubble (rubble that is comprised of remnants of biological origin, such as coral skeletons) with a low to moderate seabed relief from the seabed imagery. Two sediment samples were attempted at Site 15, with refusal (no material able to be recovered) both times suggesting a hard seabed. The species diversity at this site was noted to be higher in comparison to other sites, with more small crustaceans observed to be residing in the habitat provided by the rubble. Larger schooling bony fishes (possibly Amberjack) were also observed in imagery at this site.	The consolidated rubble observed from the seabed imagery is harder in comparison with other sites along the pipeline route. Determining the seabed bedform classification as a mound is difficult from the seabed imagery given the fine scale field of view of the drop camera.	
16	190	None	Irregular 3D ripples	The sediments were classified as coarse sand from the seabed imagery; the sediment sample collected at Site 16 was classified as sand with some clay and silt from the PSD data. Irregular 3D ripples are also apparent from the seabed imagery. A small number of solitary echinoderms and crustaceans were observed in the seabed imagery at Site 16.	The habitat map is considered to accurately represent the seabed at this site.	

Site Number	Approximate Depth (m)	AMP/KEF	Classification from Preliminary Habitat Map	Observed Habitat	General Comments	Example Images (laser scale = 18 cm (l) x 23 cm (h)
17	130	Ancient Coastline at 125 m Depth Contour KEF	Fine sand-mud	The sediments were classified as fine sand/mud from the seabed imagery; the sediment sample collected at Site 17 was classified as sand with some silt and clay from the PSD data. Relatively high levels of bioturbation of various sizes were observed in seabed imagery at Site 17. Some individual bony fishes were also observed here.	The habitat map is considered to accurately represent the seabed at this site.	 
18	126	Ancient Coastline at 125 m Depth Contour KEF	Coarse sand	The sediments were classified as fine sand/mud from the seabed imagery; the sediment sample collected at Site 18 was classified as predominantly sand from the PSD data. Epifauna observed in seabed imagery included an few small solitary bony fishes.	The habitat map is considered to accurately represent the seabed at this site.	 
19	120	Ancient Coastline at 125 m Depth Contour KEF	Fine sand-mud	The sediments were classified as fine sand/mud from the seabed imagery; the sediment sample collected at Site 18 was classified as sand with some clay from the PSD data. There was no epifauna observed in seabed imagery at Site 19. Bioturbation was observed to be relatively high compared to most other sites.	The habitat map is considered to accurately represent the seabed at this site.	 

4.2 Physico-Chemical Characteristic (Water Quality)

A total of 22 water column profiles were recorded from 20 survey sites. The shallowest site was Site 19, with a depth of 120 m; the deepest site was Site 6, with a depth of 432 m. Water column profiles for all sites are presented in Sections 4.2.1 to 4.2.7 and for individual sites in Appendix K.

4.2.1 Temperature

Figure 4-1 shows the temperature profile of all sampling sites; individual site profiles are presented in Appendix K. Water temperatures ranged from 9.3 to 30.7 °C and were highest, and most stable, in the upper surface waters down to 50 m. Between 50 and 200 m depth, the gradient in temperature decrease is the steepest, with about 5 °C decrease with every 50 m of depth. Where data was collected at sites deeper than 200 m, temperature continued to reduce as depth increased, though the rate of change decreased. The lowest water temperatures were recorded at the deepest sites profiled.

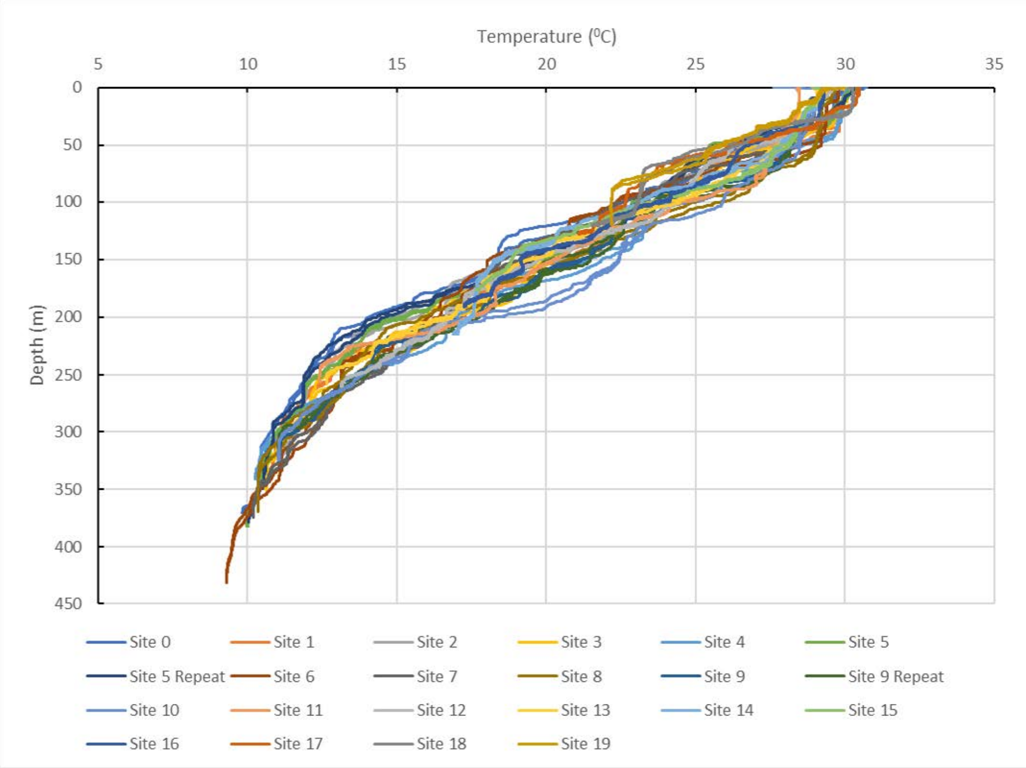

Figure 4-1: Temperature (°C) depth (m) profile at all sampling sites

4.2.2 Conductivity

Figure 4-2 shows the conductivity profile of all sampling sites; individual site profiles are presented in Appendix K.The conductivity ranged from 32.27 to 58.73 mS/cm. Conductivity values recorded displayed a similar trend to water temperature and were most stable in the upper surface waters, down to about 50 m. Between 50 and 200 m depth, the gradient of decline is steepest. The reduction in conductivity continued to decline with depth beyond 200 m, though the rate of change decreased beyond 200 m. The lowest conductivity values recorded were associated with the deepest sites profiled.

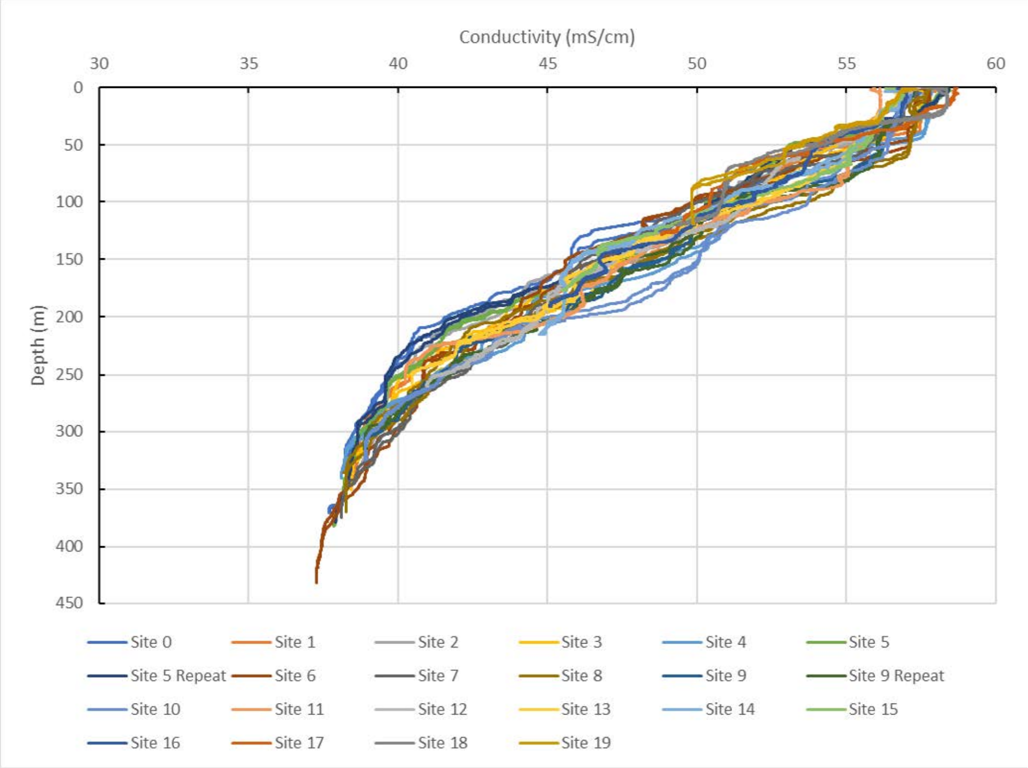

Figure 4-2: Conductivity (mS/cm) depth (m) profile at all sampling sites

4.2.3 Salinity

Figure 4-3 shows the salinity profile of all sampling sites, individual site profiles are presented in Appendix K. Salinity ranged from 34.20 to 35.09 PSU and remained relatively constant between this range throughout the depth profile (Figure 4-3).

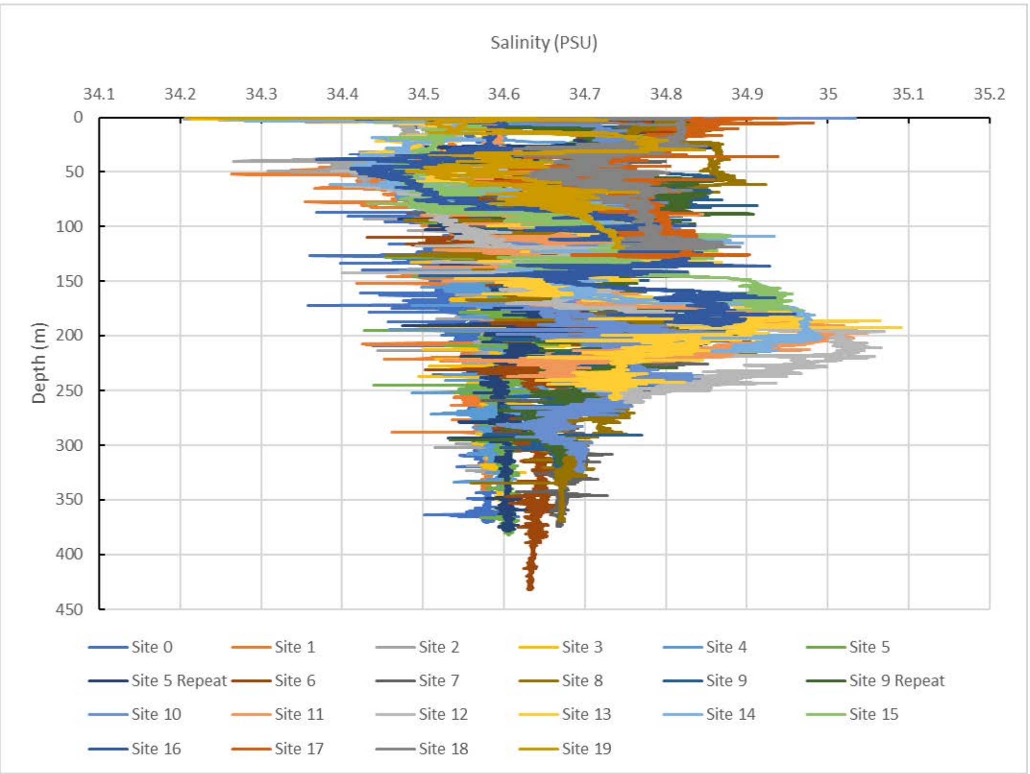

Figure 4-3: Salinity (PSU) depth (m) profile at all sampling sites

4.2.4 Turbidity

Figure 4-4 shows the turbidity profile of all sampling sites; individual site profiles are presented in Appendix K. Any recorded negative values have been corrected to 0. The measurement of negative NTU values is attributable to water that is clearer than the calibration fluid (Letterman et al., 2004). The range of turbidity varied from 0 to 2.35 NTU. Turbidity from each site displayed consistent readings throughout the water column. Sites 4, 5, 5 Repeat, 8 and 19 were around the range of 0 NTU. Sites 0, 1, 11, 13, 15 and 16 varied between 0.5 and 1.0 NTU. Sites 3, 6, 7, 9, 9 Repeat, 10, 14 and 17 were between 1 to 1.5 NTU. Site 2 was around the range of 1.8 and Sites 12 and 18 had the highest NTU, with values between 2.1 to 2.4 (Figure 4-4). The passage of tropical cyclone Veronica did not affect turbidity values.

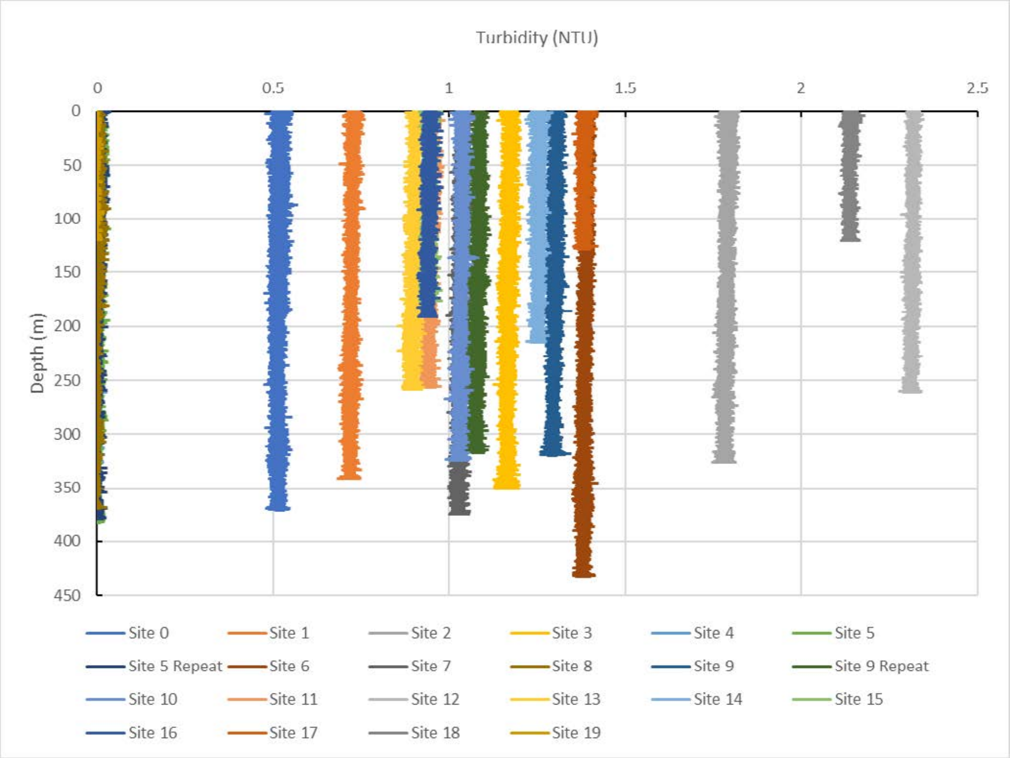

Figure 4-4: Turbidity (NTU) depth (m) profile at all sampling sites

4.2.5 Dissolved Oxygen

Only profile data from the instrument recovery (i.e. from the sea floor to the surface) was collated in Figure 4-5. The range of oxygen (%Sat) recorded was from 26% to 79%. There was a general trend of decreased saturation with depth. Dissolved oxygen values at Sites 13, 14, 15, 16 and 19 were significantly lower in comparison with other sites. The data from these sites is considered erroneous and is not presented.

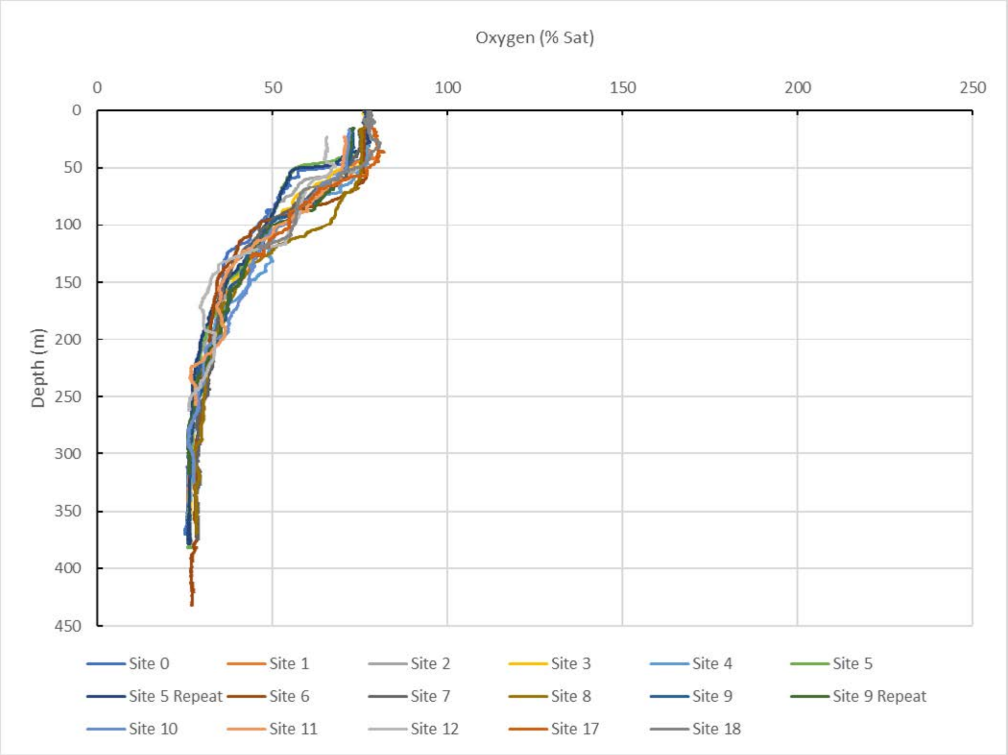

Figure 4-5: Oxygen (% Sat) depth (m) profile at all sampling sites

4.2.6 pH

Only the profile data from the instrument retrieval (i.e. from the sea floor to surface) was plotted in Figure 4-6. The range of pH was between 8.47 to 8.97. pH was observed to decrease with depth (Figure 4-6).

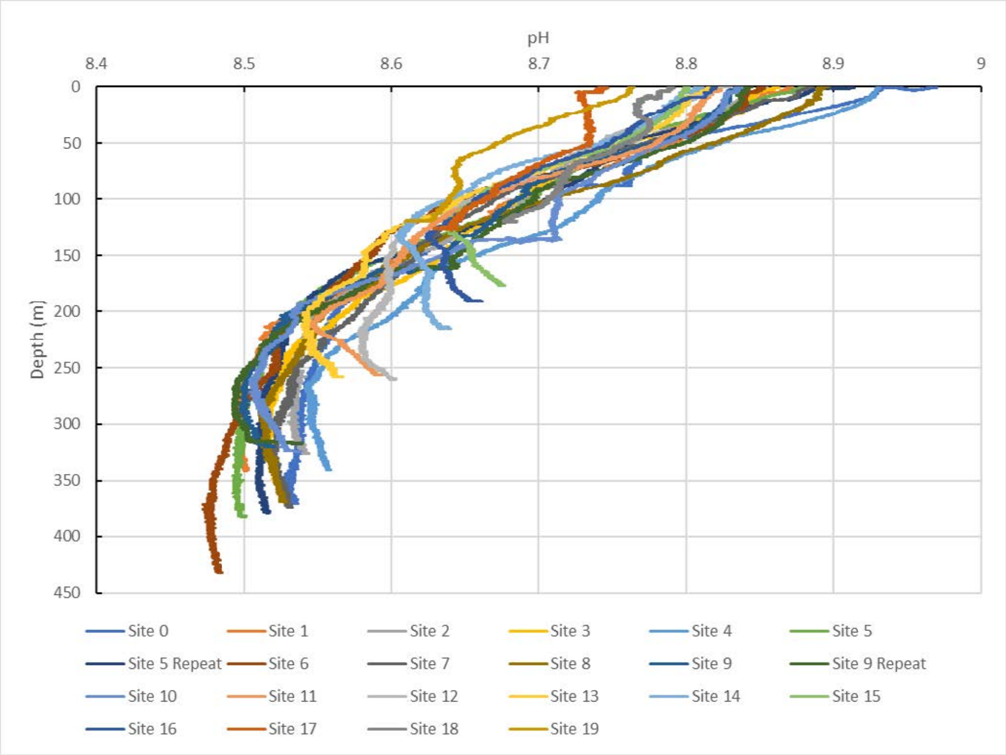

Figure 4-6: pH depth (m) profile at all sampling sites

4.2.7 Fluorescence

At all sites, there was a general trend of increasing fluorescence with depth (Figure 4-7), which is expected to be a result of nutrient levels increasing with depth (Section 4.2.10).

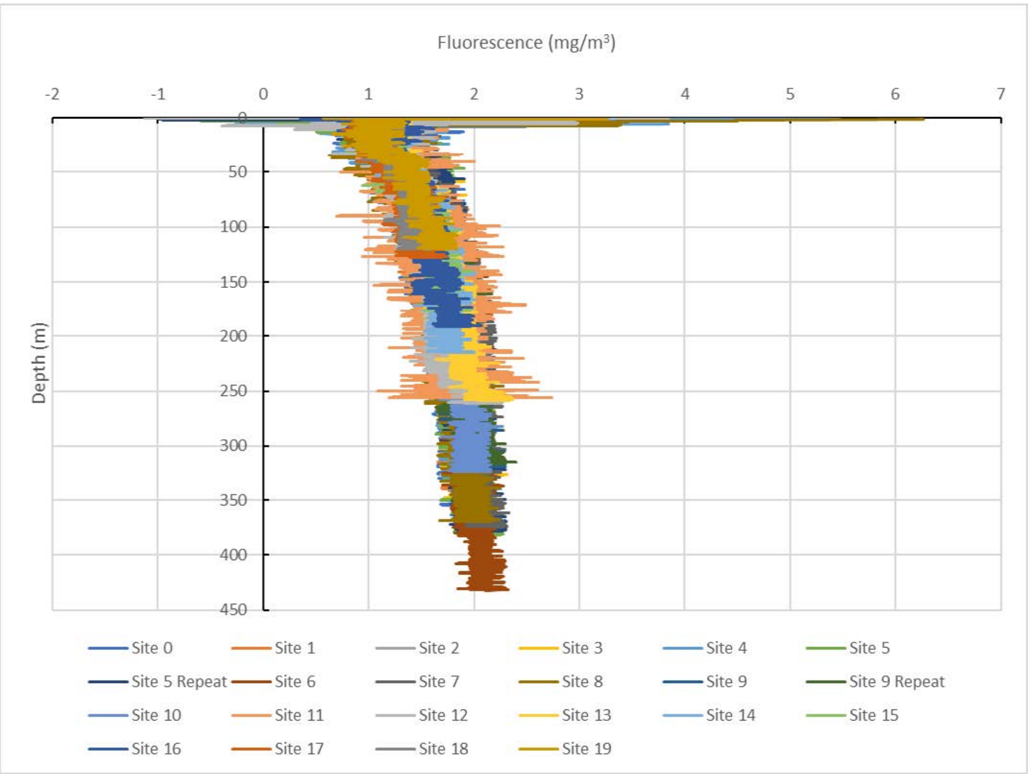

Figure 4-7: Fluorescence (mg/m^3) depth (m) profile at all sampling sites

4.2.8 Trace Metals

A summary of the results from water samples collected at mid, surface and near bottom from the 20 survey sites is presented in Sections 4.2.8.1 to 4.2.10.4. Total metals concentrations were below the ANZECC 99% species protection level at most sampling sites, except for Copper in the surface samples at Sites 2 and 8. The remaining trace metals concentrations were all below the ANZECC/ARMACANZ (2000) 99% trigger level for marine water.

4.2.8.1 Aluminium

There is no trigger level for aluminium in marine water in the Australian & New Zealand Guidelines for Fresh & Marine Water Quality (2018) or the ANZECC/ARMACANZ (2000) guidelines. The aluminium concentration ranged from less than 5 to 19 µg/L (Figure 4-8). Most sites were below the LoR except for Site 0 (all depths) and the mid water sample at Site 18.

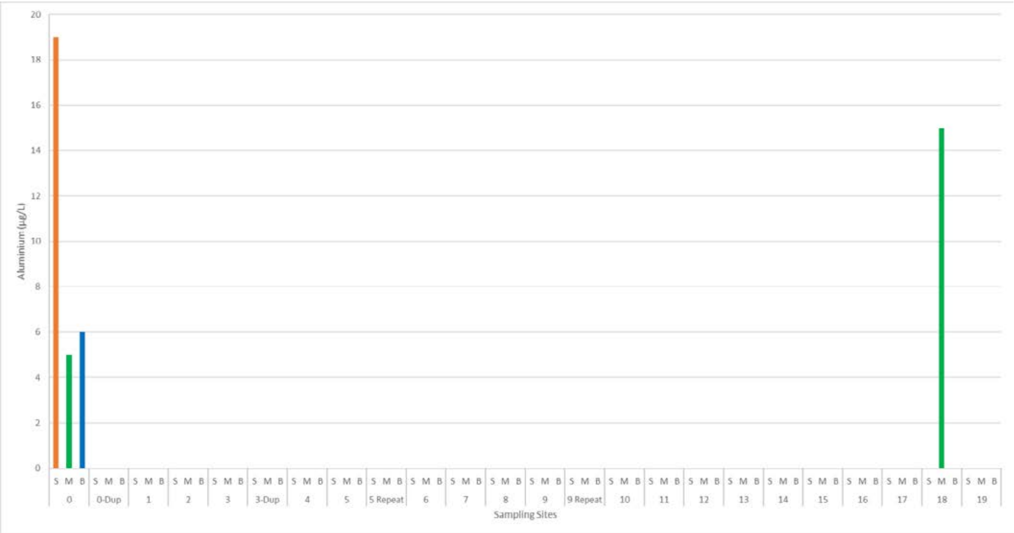

Figure 4-8: Aluminum concentration (µg/L) in marine water of all sampling sites to their relevant depth (Surface (S), Mid (M) and Bottom (B))

4.2.8.2 Arsenic

There is no trigger level for arsenic in marine water in the Australian & New Zealand Guidelines for Fresh & Marine Water Quality (2018) or the ANZECC/ARMACANZ (2000) guidelines. The arsenic concentration ranged from 1.4 to 2.1 µg/L, with minimal variation between sites and depths (Figure 4-9). The maximum concentration was observed in the bottom depth of Sites 1, 8, 12 and 13. The minimum concentration was observed in surface depth of Site 15. Arsenic concentrations are significantly lower than those detected in other regional baseline surveys (Gardline, 2009)

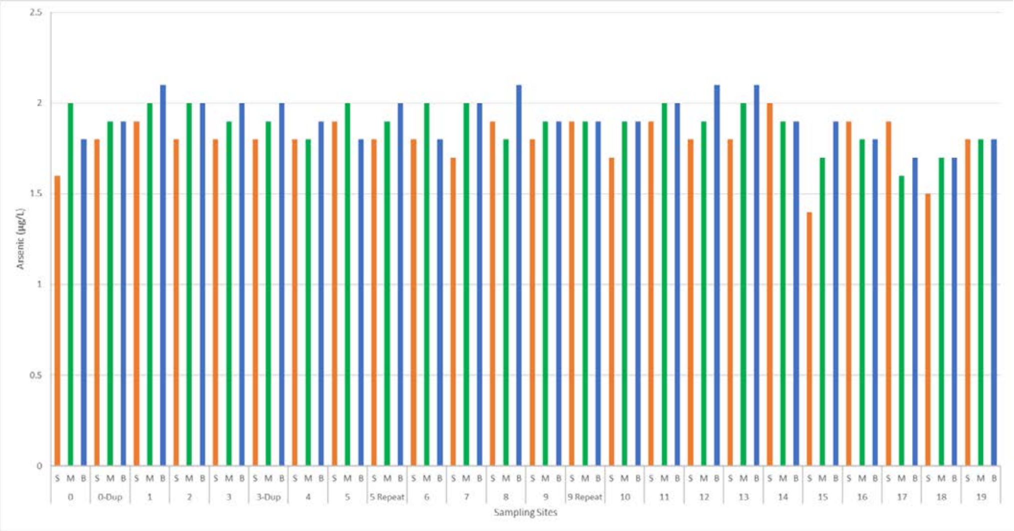

Figure 4-9: Arsenic concentration (µg/L) in marine water of all sampling sites to their relevant depth (Surface (S), Mid (M) and Bottom (B))

4.2.8.3 Barium

There is no trigger level for barium in marine water in the Australian & New Zealand Guidelines for Fresh & Marine Water Quality (2018) or the ANZECC/ARMACANZ (2000) guidelines. The barium concentration ranged from 5 to 18 µg/L (Figure 4-10). Slight variation was observed between sites with no apparent spatial trends. While there is no guideline value for Barium it is commonly associated with drilling muds and may become present in the water column through the resuspension of these muds, however much higher levels of Barium and strong stratification between bottom and mid samples would be expected from any anthropogenic contamination.

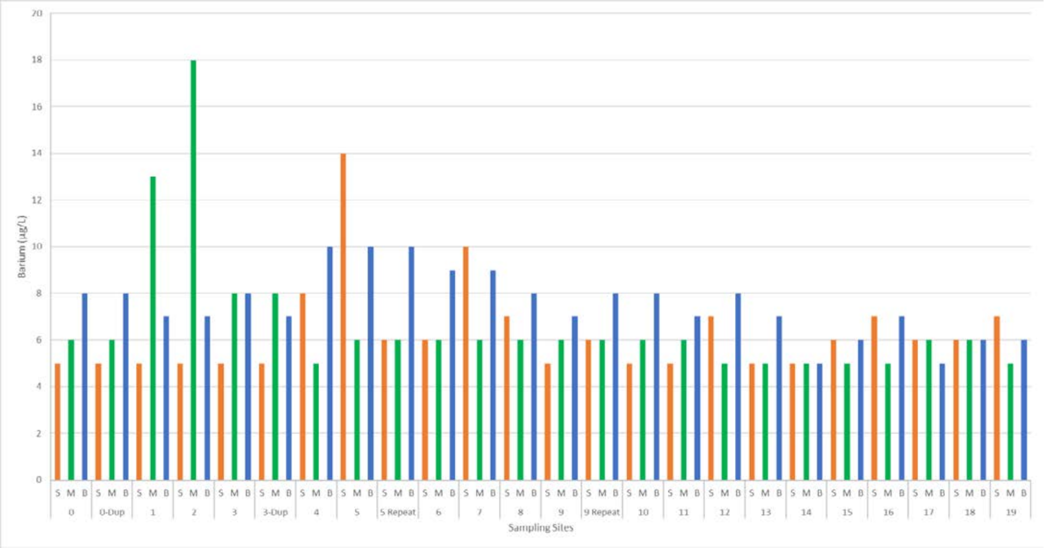

Figure 4-10: Barium concentration (µg/L) in marine water of all sampling sites to their relevant depth (Surface (S), Mid (M) and Bottom (B))

4.2.8.4 Cadmium

All results for Cadmium were below the LoR.

4.2.8.5 Chromium

Chromium concentrations for all sampling sites are below the 99% level of species protection default guideline value (DGV) for Chromium III in the Australian & New Zealand Guidelines for Fresh & Marine Water Quality (2018) (7.7 µg/L) (Figure 4-11). The concentration ranged from less than 0.5 to 1.9 µg/kg.

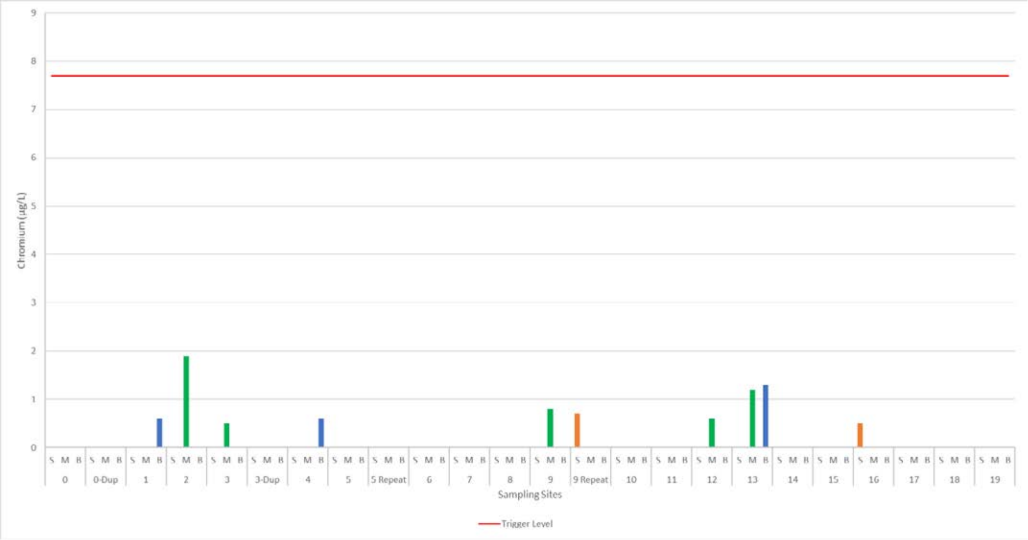

Figure 4-11: Chromium concentration (µg/L) in marine water of all sampling sites to their relevant depth (Surface (S), Mid (M) and Bottom (B))

4.2.8.6 Copper

Copper concentration for most sampling sites are below the 99% level of species protection DGV for copper in the Australian & New Zealand Guidelines for Fresh & Marine Water Quality (2018) (0.3 µg/L), except at Sites 2 and 8 (Figure 4-12). The concentrations ranged from less than 0.2 to 0.7 µg/kg.

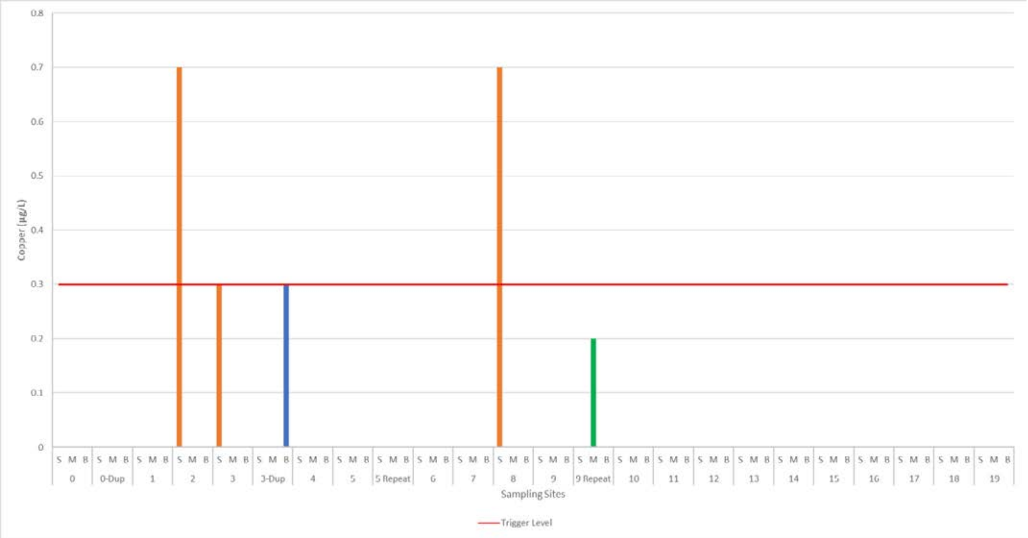

Figure 4-12: Copper concentration (µg/L) in marine water of all sampling sites to their relevant depth (Surface (S), Mid (M) and Bottom (B))

4.2.8.7 Cobalt

Cobalt concentrations for all sampling sites are below the LoR of less than 0.05 µg/L.

4.2.8.8 Iron

There is no trigger level for iron in marine water in the Australian & New Zealand Guidelines for Fresh & Marine Water Quality (2018) or the ANZECC/ARMACANZ (2000) guidelines. The iron concentration ranged from less than 5 (LoR) to 18 µg/L (Figure 4-13). Slight variation was observed between sites, with no apparent spatial trends.

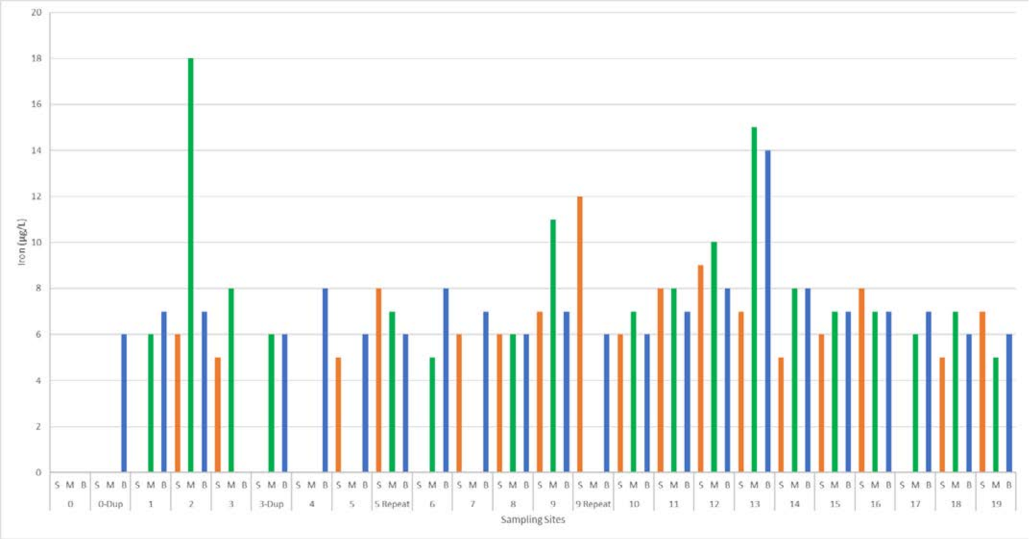

Figure 4-13: Iron concentration (µg/L) in marine water of all sampling sites to their relevant depth (Surface (S), Mid (M) and Bottom (B))

4.2.8.9 Mercury

Mercury concentrations for all sampling sites are below the LoR.

4.2.8.10 Nickel

Nickel concentrations for all sampling sites are below the LoR.

4.2.8.11 Lead

Lead concentrations for all sampling sites are below the 99% level of species protection DGV for lead in the Australian & New Zealand Guidelines for Fresh & Marine Water Quality (2018) (2.2 µg/L) (Figure 4-14). The concentration ranged from less than 0.2 (LoR) to 0.5 µg/l.

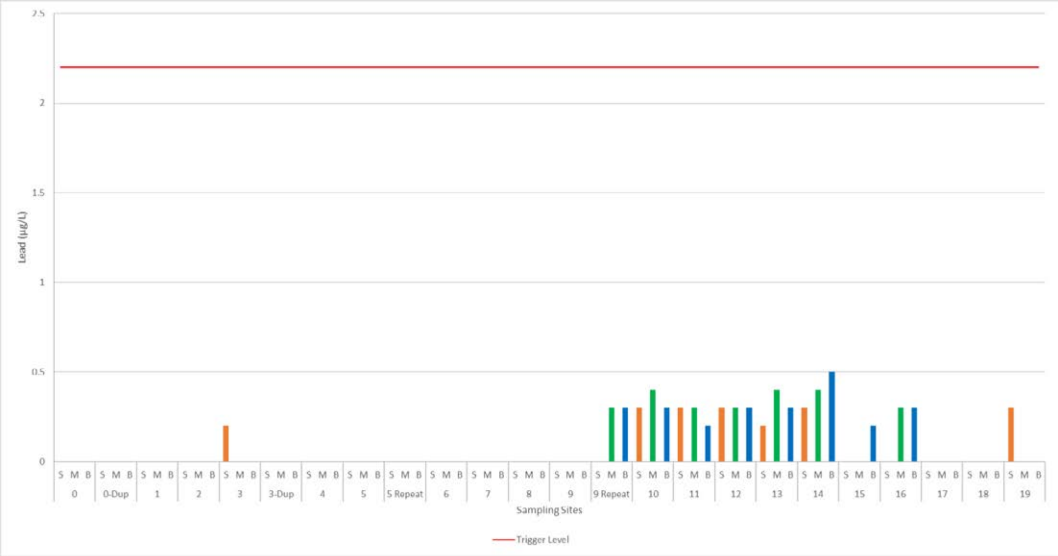

Figure 4-14: Lead concentration (µg/L) in marine water of all sampling sites to their relevant depth (Surface (S), Mid (M) and Bottom (B))

4.2.8.12 Tin

There is no trigger level for tin in marine water and all results were below the LoR of less than 5 µg/L.

4.2.8.13 Vanadium

Vanadium concentration of all sampling sites is below the 99% level of species protection DGV for vanadium in the Australian & New Zealand Guidelines for Fresh & Marine Water Quality (2018) (50 µg/L) (Figure 4-15). The concentration ranged from 0.8 to 5.8 µg/L, with minimal variation observed between sites.

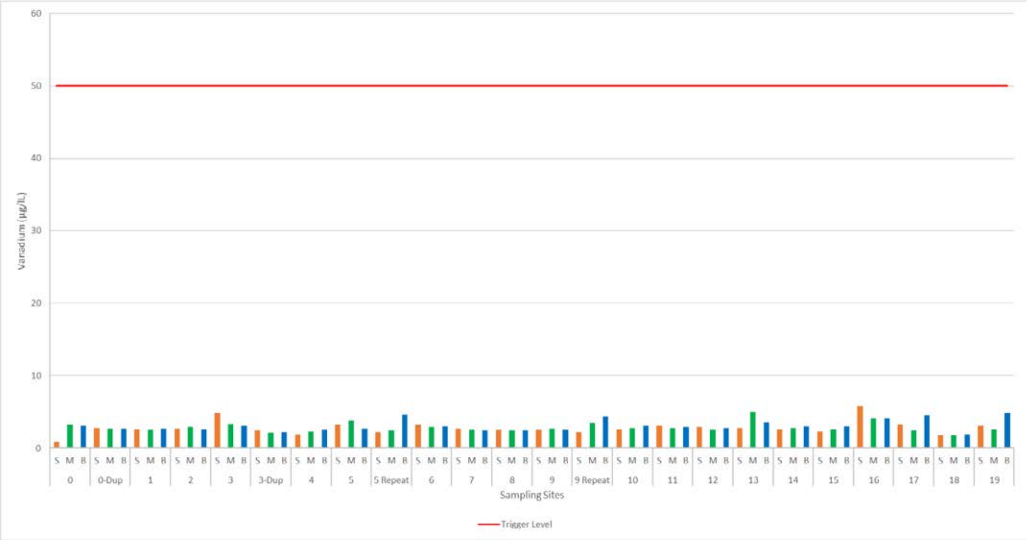

Figure 4-15: Vanadium concentration (µg/L) in marine water of all sampling sites to their relevant depth (Surface (S), Mid (M) and Bottom (B))

4.2.8.14 Zinc

Zinc concentration for all sampling sites is below the LoR of less than 5 µg/L.

4.2.9 Hydrocarbons TPH, TRH and PAH

All concentrations of TPH, TRH and PAHs were below the LoR.

4.2.10 Nutrients

Nutrients increased with depth at all sites and were generally below ANZECC trigger values for slightly disturbed ecosystems in tropical Australia (ANZECC/ARMCANZ, 2000) and, where available, the DGVs for the 99% level of species protection from the Australian & New Zealand Guidelines for Fresh and Marine Water Quality (2018).

4.2.10.1 TN

Nitrogen concentrations increased with depth at all sites. Surface waters were all below the LoR or trigger level for total nitrogen in offshore (tropical) marine environments (refer to table 3.3.4 of ANZECC/ARCANZ, 2000) of 0.1 mg/L.

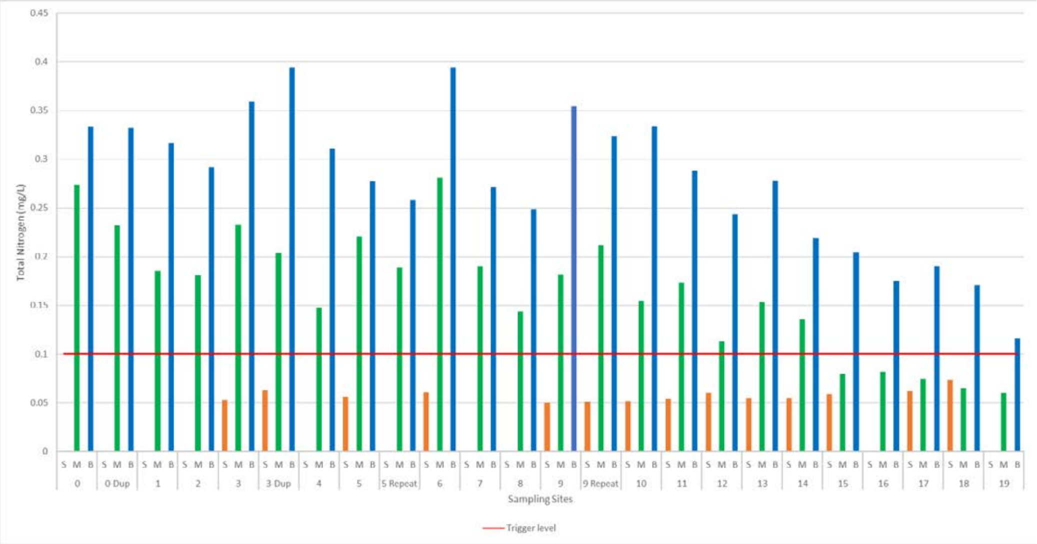

Figure 4-16: Total nitrogen concentration (mg/L) in marine water of all sampling sites to their relevant depth (Surface (S), Mid (M) and Bottom (B))

4.2.10.2 TP

Total Phosphorus concentrations increased with depth at all sites. All surface samples were slightly above the trigger level for total phosphorus in offshore (tropical) marine environments of 10 µg/L (refer to table 3.3.4 of ANZECC/ARMCANZ, 2000) (Figure 4-17).

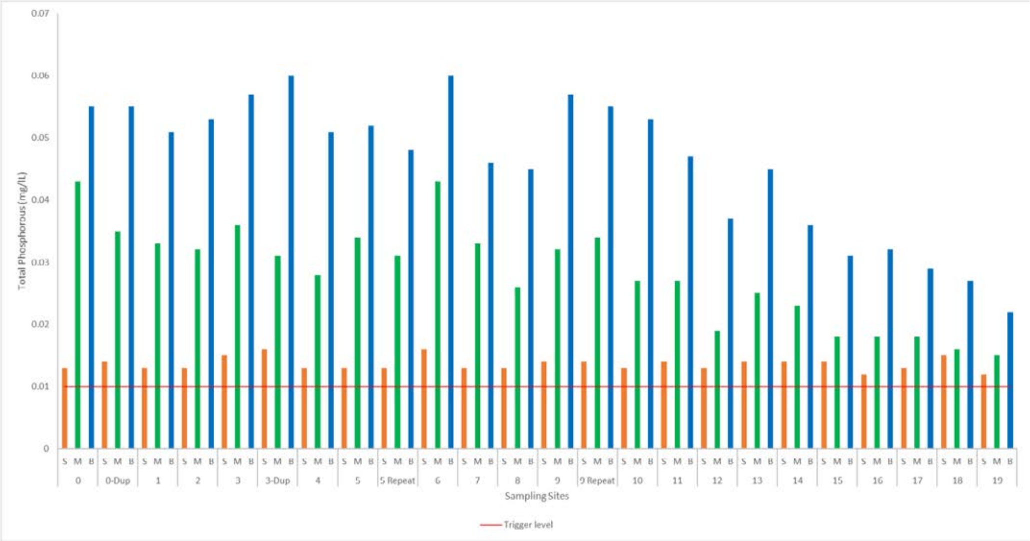

Figure 4-17: Total phosphorous (mg/L) in marine water of all sampling sites to their relevant depth (Surface (S), Mid (M) and Bottom (B))

4.2.10.3 Nitrite and Nitrate

There is no trigger level for individual nitrite and nitrate in marine water. Concentrations ranged from 0.002 to 0.344 mg/L, with concentration increasing with depth. Concentrations are similar to those observed in other regional marine baseline surveys (Gardline, 2009).

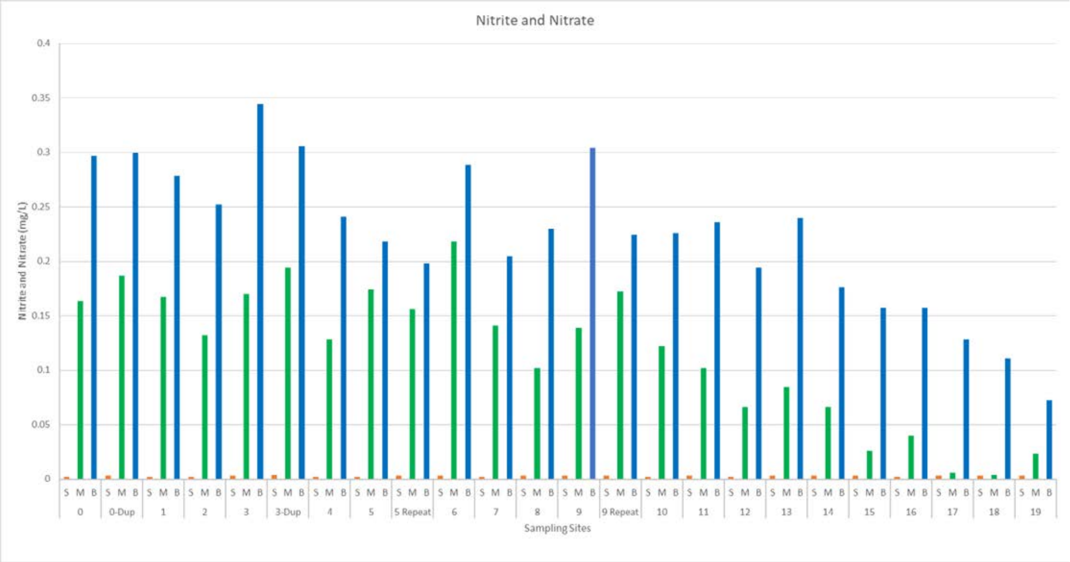

Figure 4-18: Nitrite and nitrate (mg/L) in marine water of all sampling sites to their relevant depth (Surface (S), Mid (M) and Bottom (B))

4.2.10.4 NH4

All NH4 concentrations were observed to be below the 99% level of species protection DGV for ammonia in the Australian & New Zealand Guidelines for Fresh & Marine Water Quality (2018) (0.5 mg/L) (Figure 4-19). The concentration ranged from 0.007 to 0.261 mg/L.

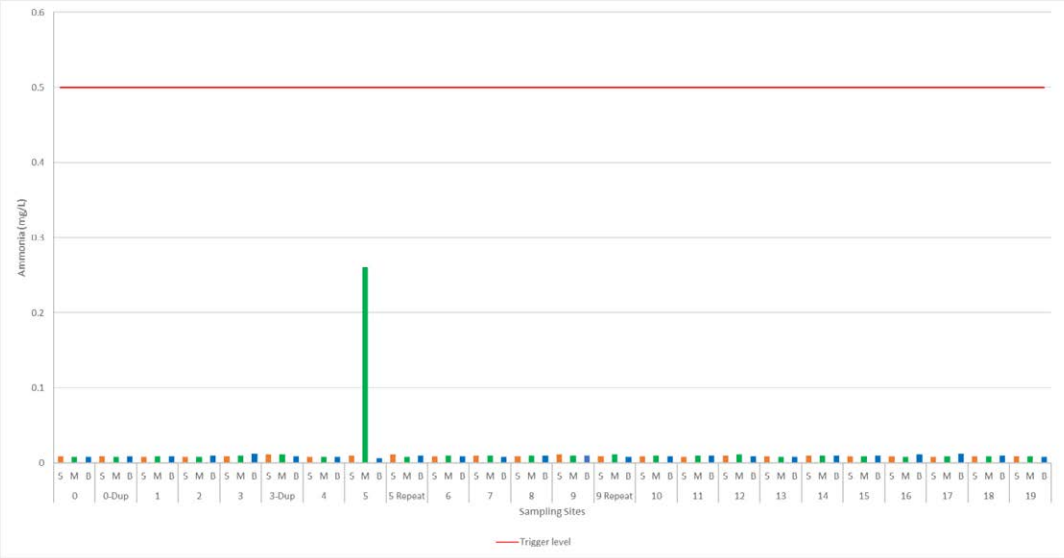

Figure 4-19: Ammonia concentration (µg/L) in marine water of all sampling sites to their relevant depth (Surface (S), Mid (M) and Bottom (B))

4.3 Sediment Quality

4.3.1 Trace Metals

4.3.1.1 Aluminium

There is no DGV in the Australian & New Zealand Guidelines for Fresh & Marine Water Quality (2018) or an Interim Sediment Quality Guideline (ISQG) in ANZECC/ARMCANZ (2000) for aluminium in sediments. The aluminium concentration ranged from 600 to 4620 mg/kg, with variation between sites (Figure 4-20). The maximum concentration occurred at Site 0 and minimum concentration at Site 16. Though no DGV exist for aluminium, concentrations were much lower than values estimated to be naturally occurring in Pilbara coastal sediments (DEC, 2006).

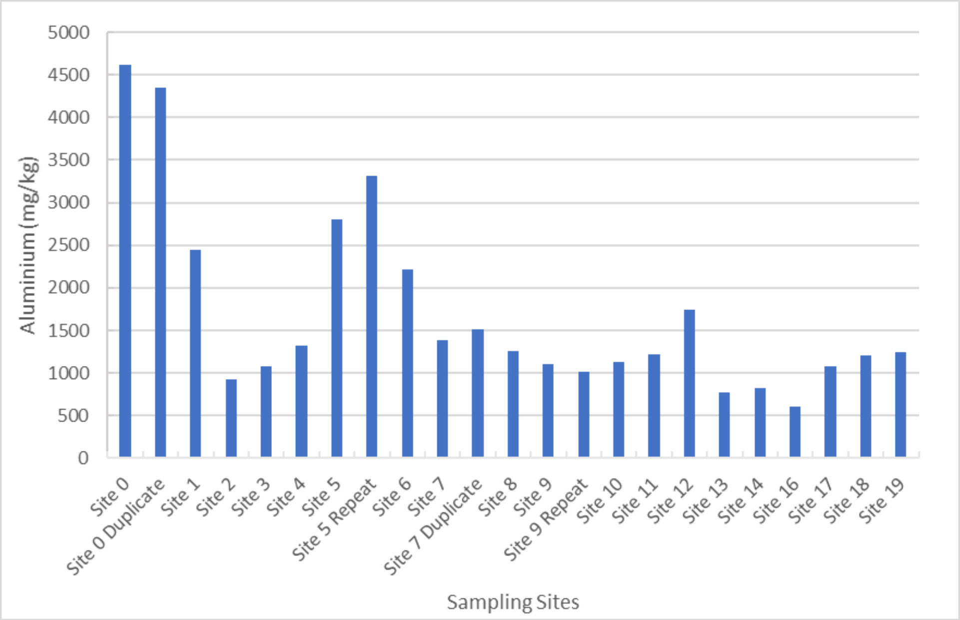

Figure 4-20: Aluminum concentration (mg/kg) in sediment samples for all sites

4.3.1.2 Barium

There is no DGV in the Australian & New Zealand Guidelines for Fresh & Marine Water Quality (2018) or an ISQG in ANZECC/ARMCANZ (2000) for barium in sediments. The barium concentration ranged from 7.9 to 46 mg/kg, with some variation between sites (Figure 4-21). The maximum concentration occurred at Site 5 Repeat and minimum concentration at Site 9 Repeat.

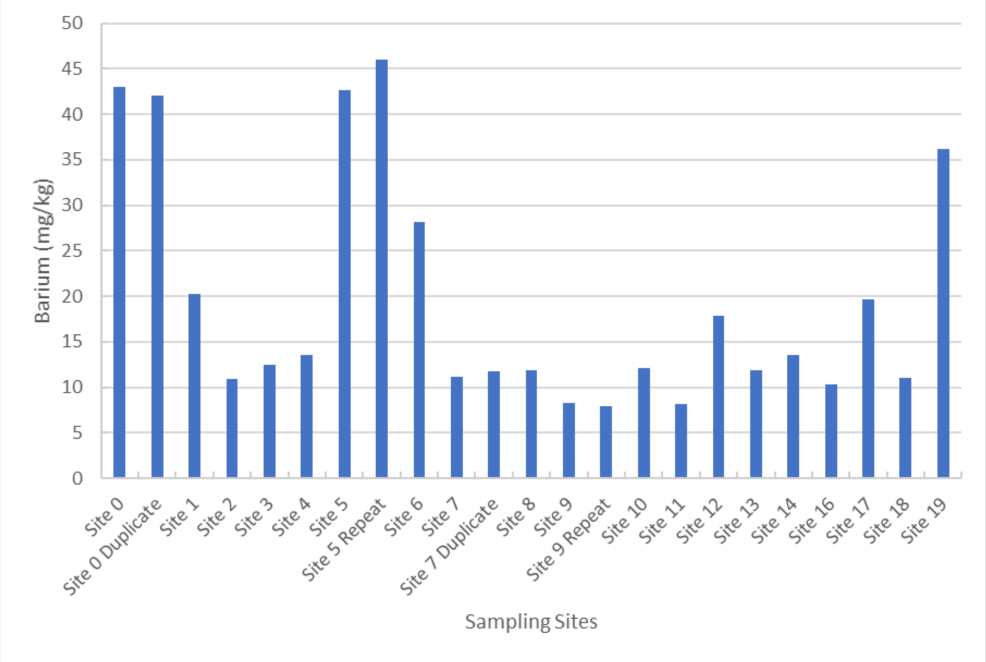

Figure 4-21: Barium concentration (mg/kg) in sediment samples for all sites

4.3.1.3 Cadmium

Cadmium concentration for all sampling sites is below the DGV for sediment quality in the Australian & New Zealand Guidelines for Fresh & Marine Water Quality (2018) (1.5 mg/kg) (Figure 4-22). The concentration ranged from 0.1 to 0.2 mg/kg, showing minimal variation between sites.

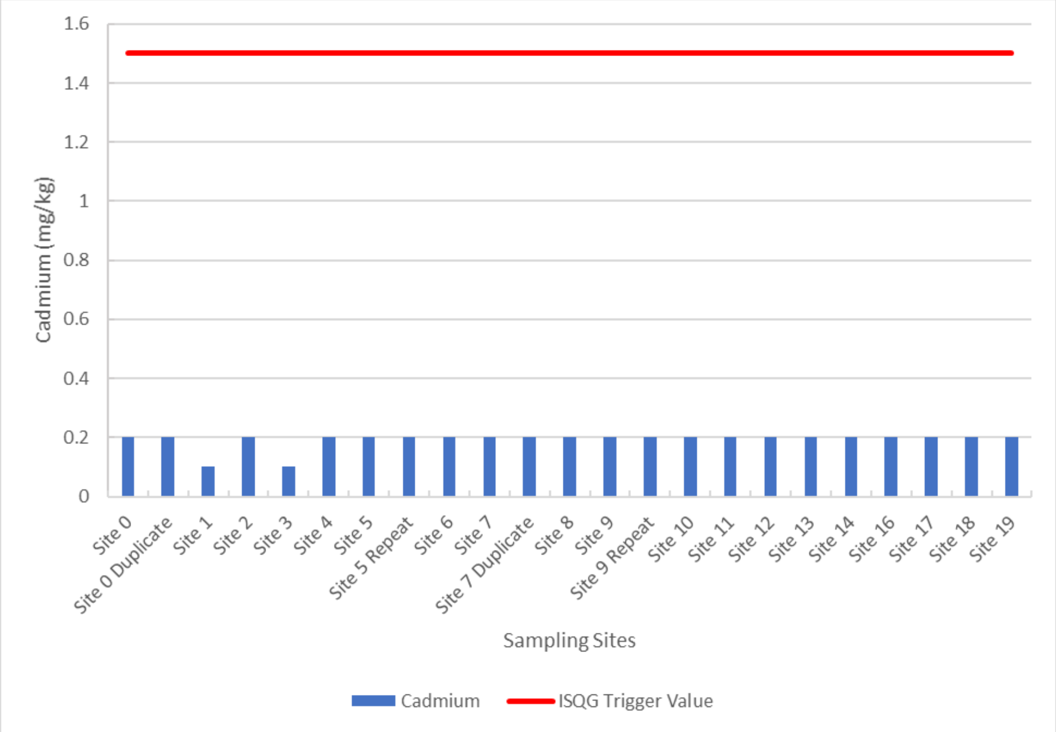

Figure 4-22: Cadmium concentration (mg/kg) in sediment samples for all sites

4.3.1.4 Chromium

Chromium concentration for all sampling sites is below the DGV for sediment quality in the Australian & New Zealand Guidelines for Fresh & Marine Water Quality (2018) (80 mg/kg) (Figure 4-23). The concentration ranged from 6.2 to 15.7 mg/kg, showing minimal variation between sites.

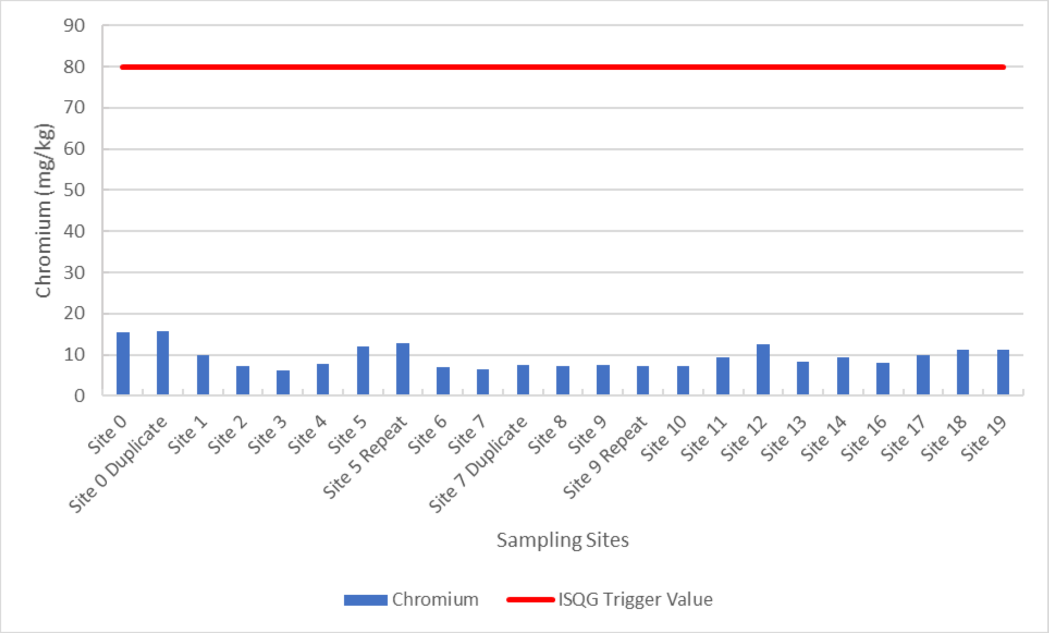

Figure 4-23: Chromium concentration (mg/kg) in sediment samples for all sites

4.3.1.5 Copper

Copper concentration for all sampling sites is below the DGV for sediment quality in the Australian & New Zealand Guidelines for Fresh & Marine Water Quality (2018) (65 mg/kg) (Figure 4-24). The concentration ranged from 2.3 to 11.4 mg/kg, showing slight variation between sites.

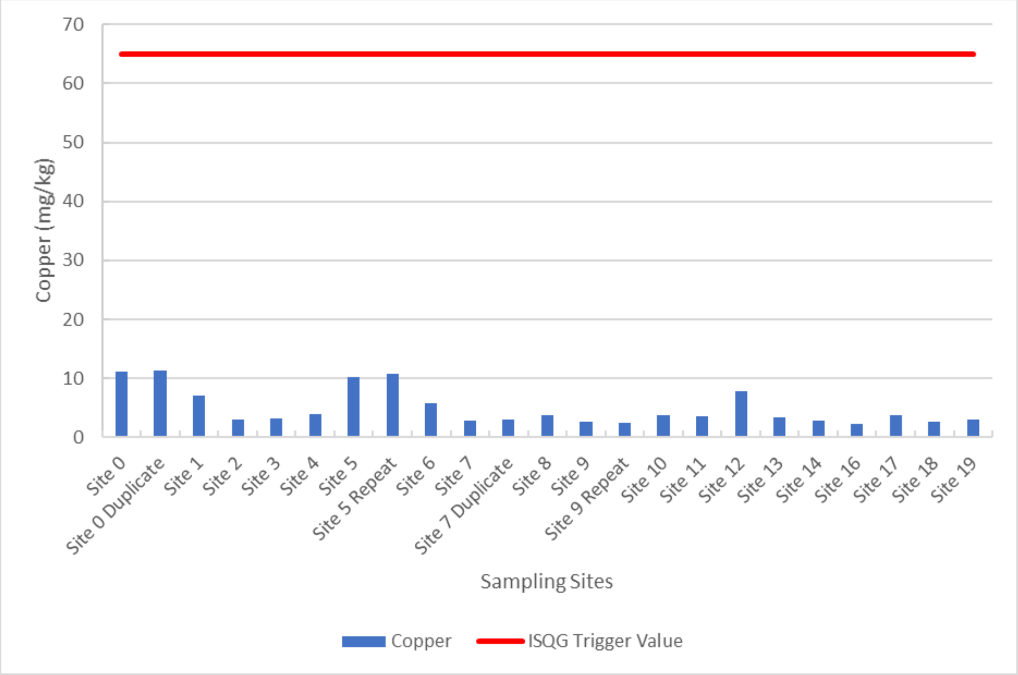

Figure 4-24: Copper concentration (mg/kg) in sediment samples for all sites

4.3.1.6 Iron

There is no DGV in the Australian & New Zealand Guidelines for Fresh & Marine Water Quality (2018) or an ISQG in ANZECC/ARMCANZ (2000) for iron in sediments. The iron concentration ranged from 1160 to 5290 mg/kg, with variation between sites (Figure 4-25). Though no DGV exist for iron, concentrations were much lower than values estimated to be naturally occurring in Pilbara coastal sediments (DEC, 2006).

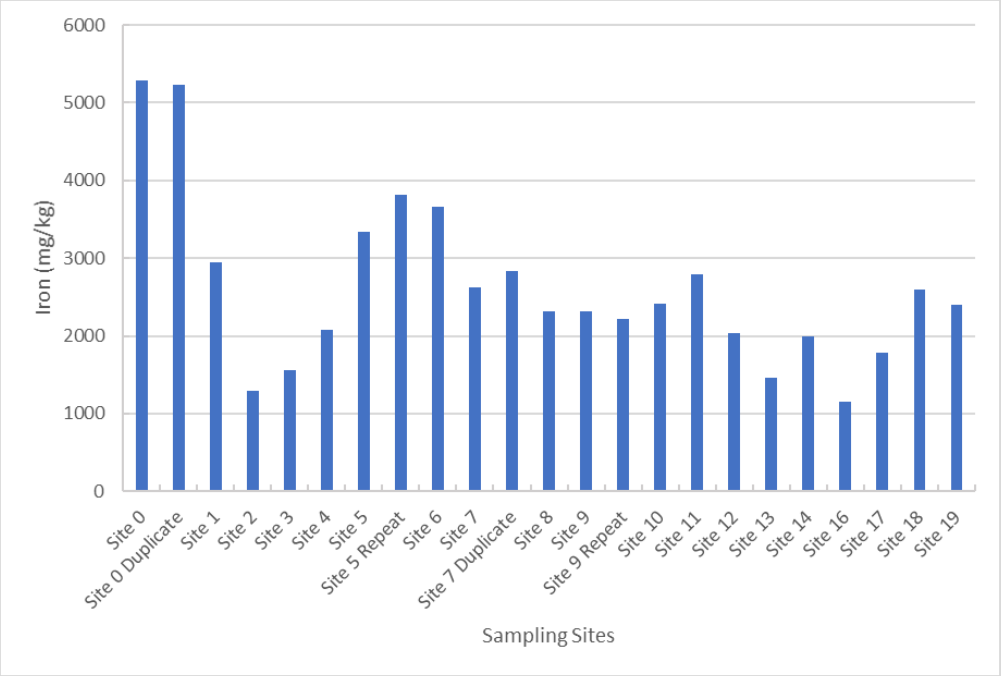

Figure 4-25: Iron concentration (mg/kg) in sediment samples for all sites

4.3.1.7 *Lead*

Lead concentration for all sampling sites is below the DGV for sediment quality in the Australian & New Zealand Guidelines for Fresh & Marine Water Quality (2018) (50 mg/kg) (Figure 4-26). The concentration ranged from less than 1 to 11.3 mg/kg, showing minimal variation between sites except for Site 6, which had the maximum concentration. The minimum concentration was observed at Sites 3, 14 and 16.

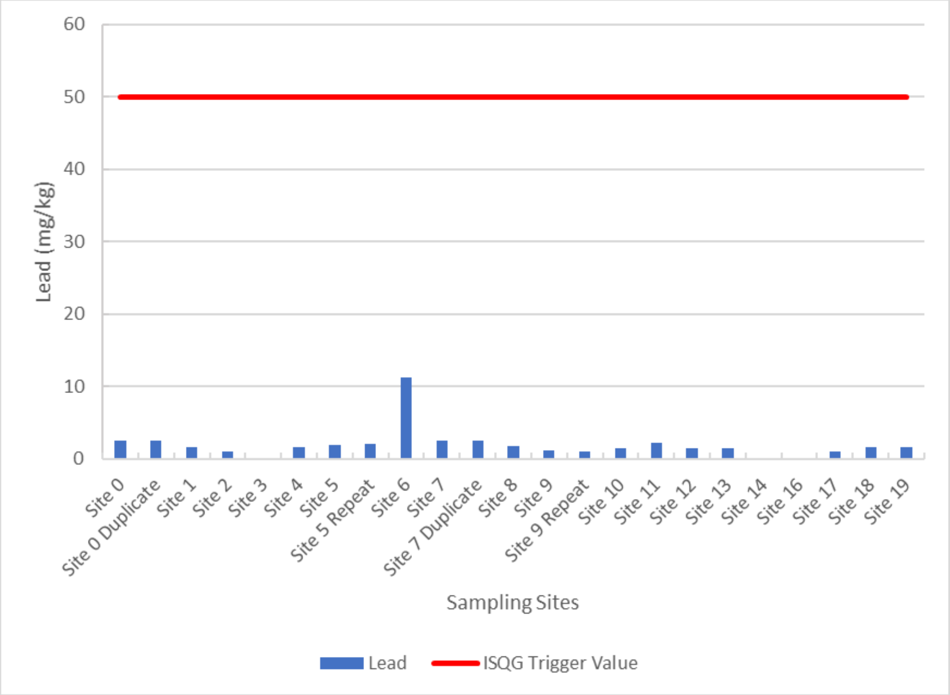

Figure 4-26: Lead concentration (mg/kg) in sediment samples for all sites

4.3.1.8 Mercury

Mercury concentration for all sampling sites is below the DGV for sediment quality in the Australian & New Zealand Guidelines for Fresh & Marine Water Quality (2018) (0.15 mg/kg) (Figure 4-27). The concentration ranged from less than 0.01 to 0.03 mg/kg, showing minimal variation between sites.

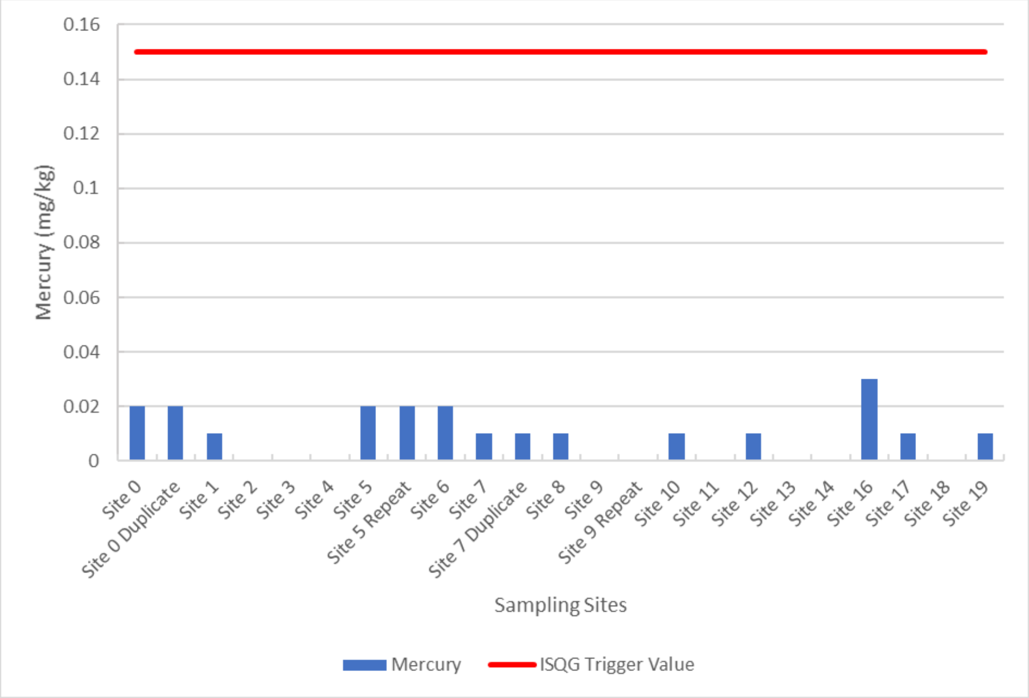

Figure 4-27: Mercury concentration (mg/kg) in sediment samples for all sites

4.3.1.9 Nickel

Nickel concentration for all sampling sites is below the DGV for sediment quality in the Australian & New Zealand Guidelines for Fresh & Marine Water Quality (2018) (21 mg/kg) except for Site 6, with the maximum concentration of 43.1 mg/kg (Figure 4-28). The concentration ranged from 3.4 to 43.1 mg/kg. Besides Site 6, minimal variation was observed between sites.

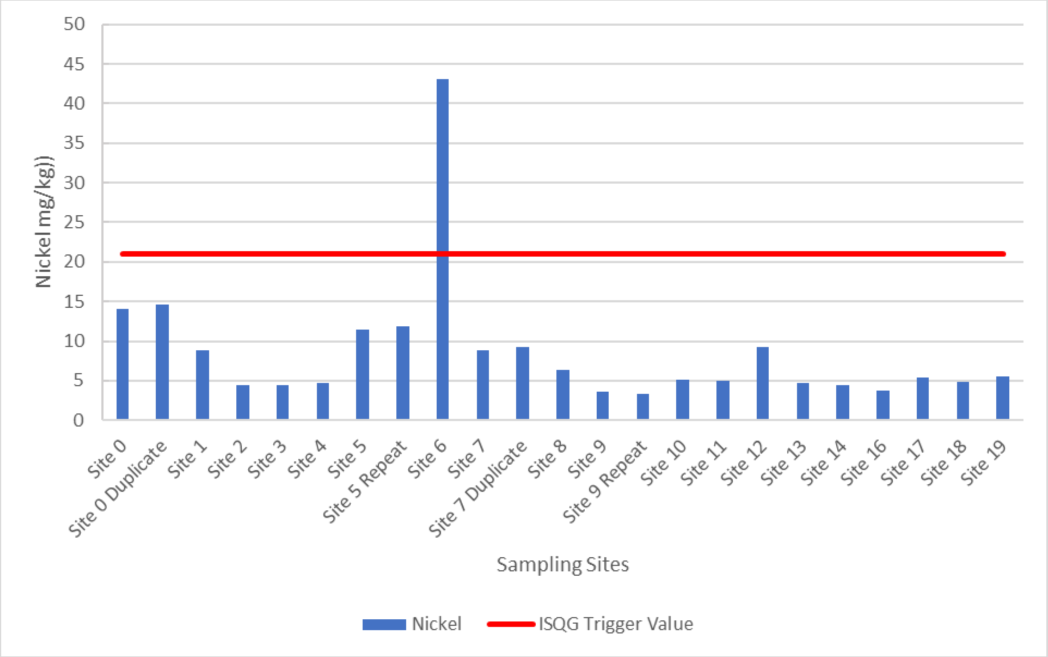

Figure 4-28: Nickel concentration (mg/kg) in sediment samples for all sites

4.3.1.10 Tin

There is no DGV in the Australian & New Zealand Guidelines for Fresh & Marine Water Quality (2018) or an ISQG in ANZECC/ARMCANZ (2000) for tin in sediments. The tin concentration ranged from less than 0.1 to 0.4 mg/kg, with minimal variation between sites (Figure 4-29).

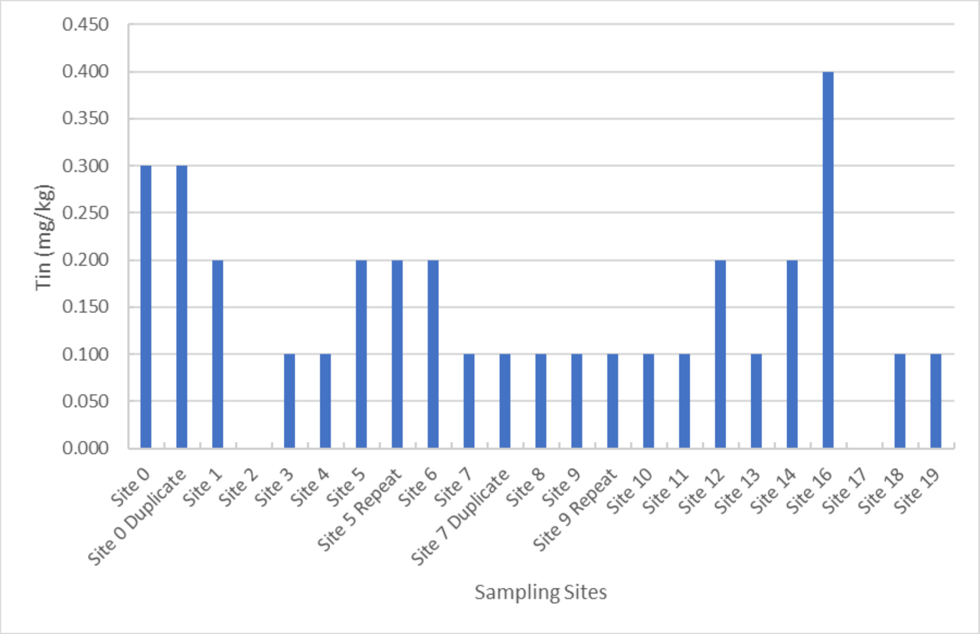

Figure 4-29: Tin concentration (mg/kg) in sediment samples for all sites

4.3.1.11 Vanadium

There is no DGV in the Australian & New Zealand Guidelines for Fresh & Marine Water Quality (2018) or an ISQG in ANZECC/ARMCANZ (2000) for vanadium in sediments. The vanadium concentration ranged from 2.5 to 10.6 mg/kg, with variation between sites (Figure 4-30).

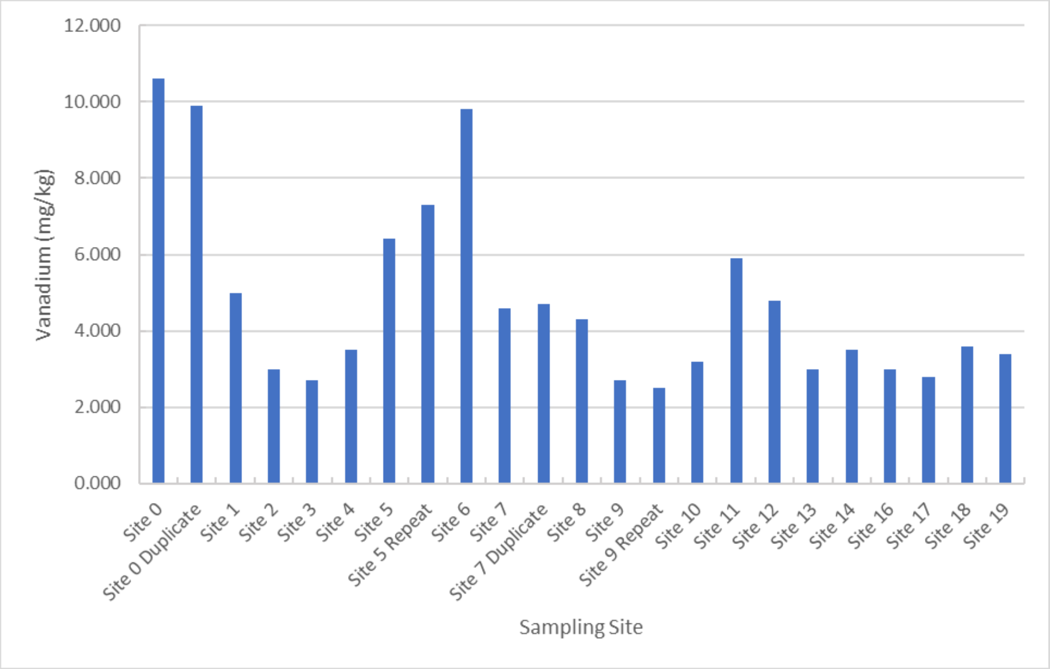

Figure 4-30: Vanadium concentration (mg/kg) in sediment samples for all sites

4.3.1.12 Zinc

Zinc concentration for all sampling sites is below the DGV for sediment quality in the Australian & New Zealand Guidelines for Fresh & Marine Water Quality (2018) (200 mg/kg) (Figure 4-31). The concentration ranged from 7.2 to 25.8 mg/kg, with slight variation observed between sites.

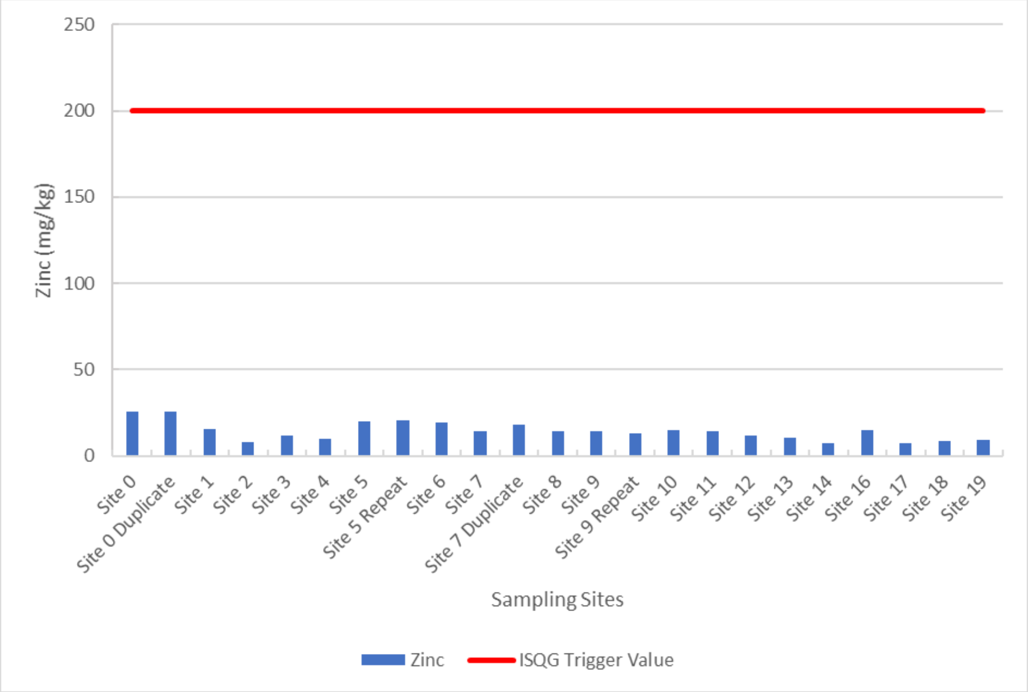

Figure 4-31: Zinc concentration (mg/kg) in sediment samples for all sites

4.3.2 Hydrocarbons

4.3.2.1 BTEX

All results for BTEX were below the LoR.

4.3.2.2 TPHs

TPH concentrations for most sampling sites are below the LoR. Sites 5 and 11 are above the LoR but well below the DGV for sediment quality in the Australian & New Zealand Guidelines for Fresh & Marine Water Quality (2018) (280 mg/kg). The TPH concentration ranged from less than 3 to 18 mg/kg. Almost all sites were below the LoR of 3 mg/kg, except for Sites 5 and 11 (Figure 4-32).

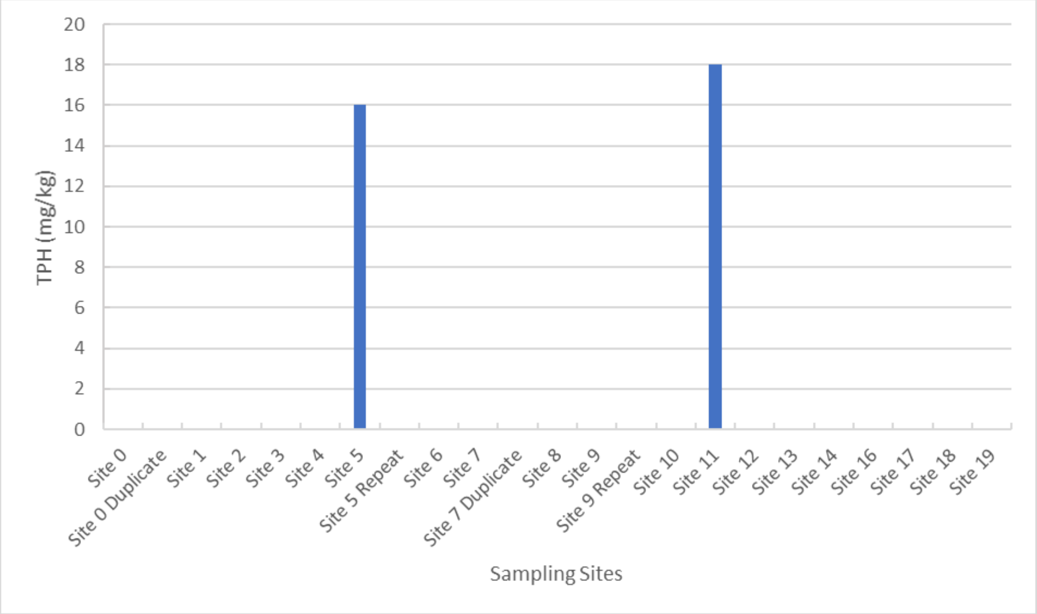

Figure 4-32: TPH concentration in sediment samples for all sites (mg/kg)

4.3.2.3 PAHs

The sum of PAH concentration for all sampling sites is below the DGV for sediment quality in the Australian & New Zealand Guidelines for Fresh & Marine Water Quality (2018) (10 mg/kg) (Figure 4-33). The concentration ranged from 4 to 139 µg/kg, with variation observed in Sites 0 Duplicate and 5, with 99 and 139 µg/kg respectively.

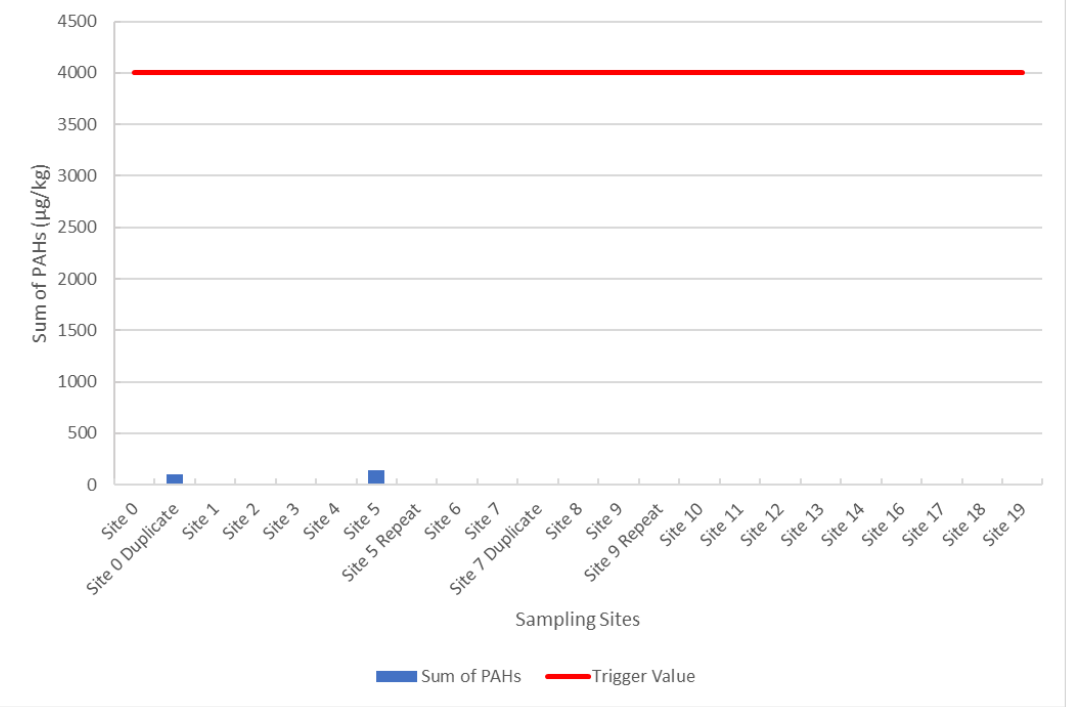

Figure 4-33: Sum of PAHs concentration in sediment samples for all sites (µg/kg)

4.3.3 Nutrients

4.3.3.1 Nitrate

There is no DGV in the Australian & New Zealand Guidelines for Fresh & Marine Water Quality (2018) or an ISQG in ANZECC/ARMCANZ (2000) for nitrate in sediments. The nitrate concentration ranged from 0.1 to 1.3 mg/kg, with slight variation between sites (Figure 4-34).

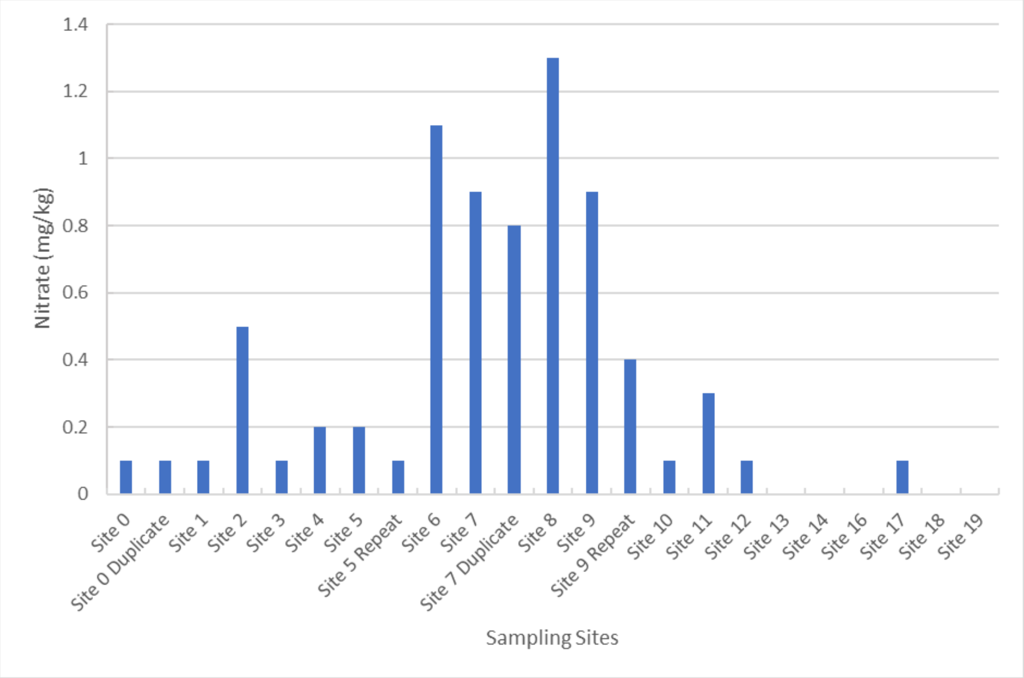

Figure 4-34: Nitrate concentration in sediment samples for all sites (mg/kg)

4.3.3.2 Nitrite

There is no DGV in the Australian & New Zealand Guidelines for Fresh & Marine Water Quality (2018) or an ISQG in ANZECC/ARMCANZ (2000) for nitrite in sediments. All concentrations were below the LoR of 0.1 mg/kg.

4.3.4 Total Organic Carbon

Slight variation of TOC was observed between sites; concentrations ranged from 0.13 to 0.84% (Figure 4-35).

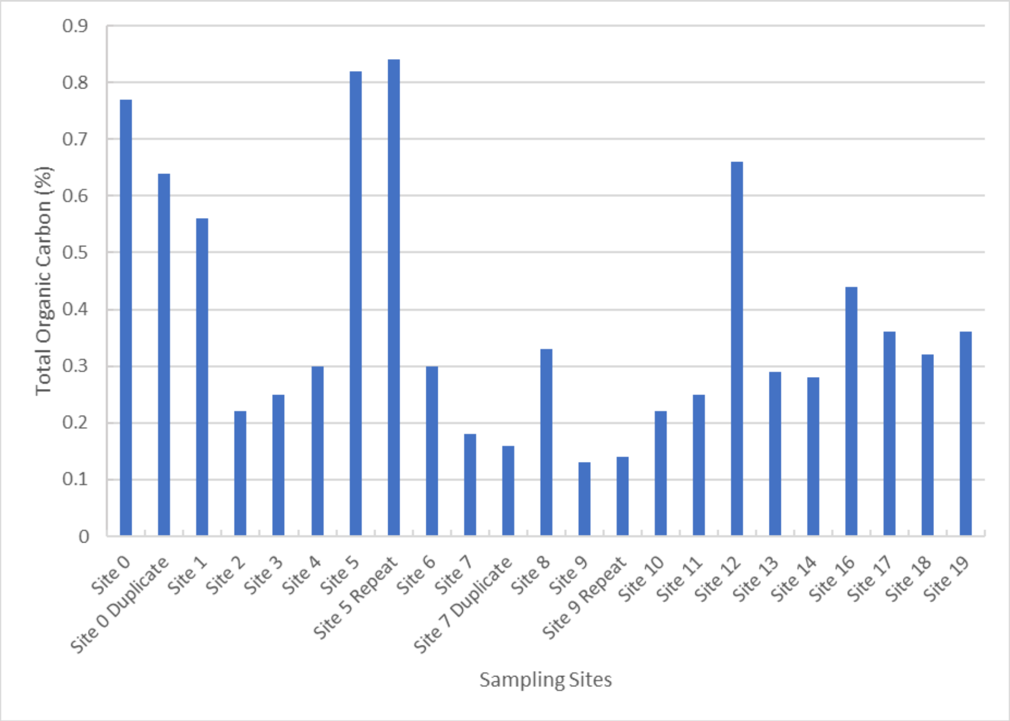

Figure 4-35: Total organic carbon concentration in sediment samples for all sites (%)

4.3.5 Total Carbon

Slight variations of total carbon were observed between sites; concentrations ranged from 9.65 to 12.1% (Figure 4-36).

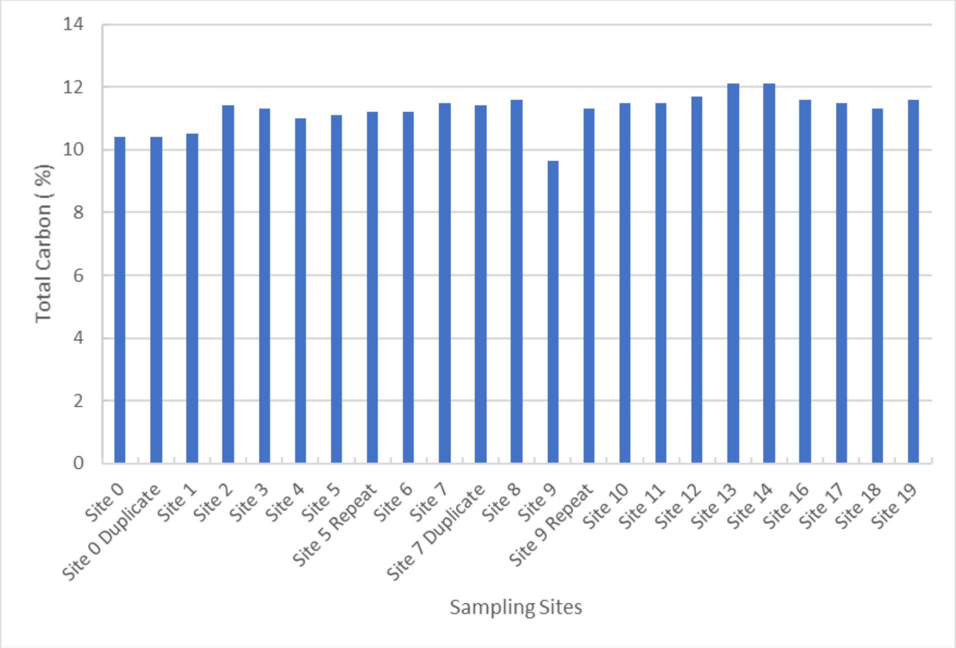

Figure 4-36: Total carbon concentration in sediment samples for all sites (%)

4.3.6 Particle Size Distribution

Sediments were typical of the North West Shelf and were dominated by Sand, with varying proportions of silt and clay along the proposed pipeline route. After multiple attempts and continued sampling refusal, likely due to consolidated substrate, sediment was unable to be recovered at Site 15.

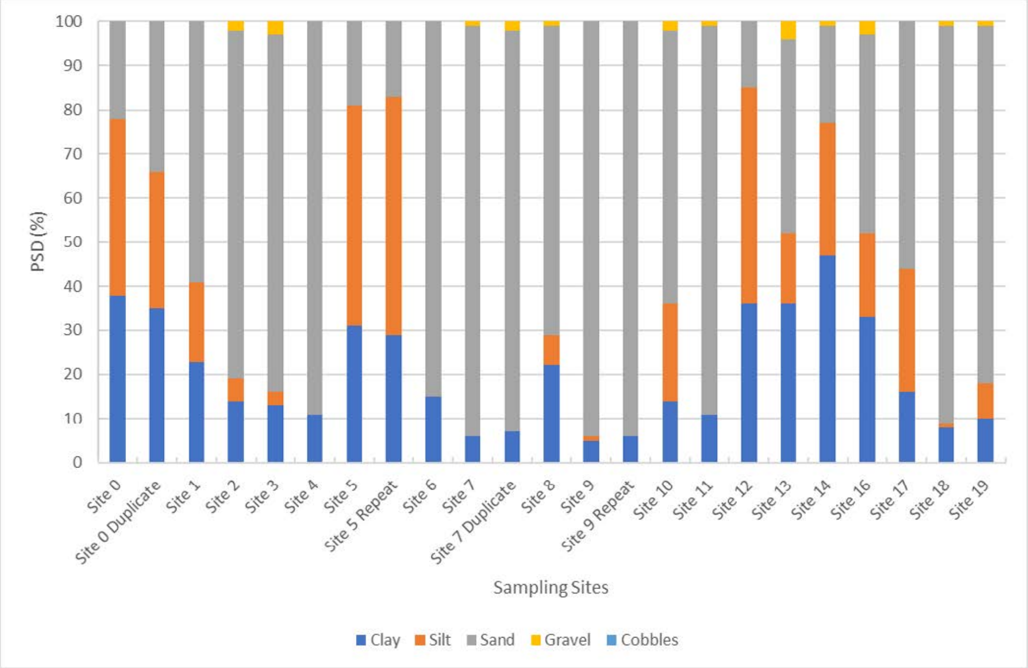

Figure 4-37: Particle size distribution for all sites

4.4 Infauna Results

4.4.1 Data Investigation

4.4.1.1 Abundance, Richness and Diversity

A summary of the abundance, richness and diversity data for each site, based on the standardised infauna abundance data is provided in Table 4-2and Appendix E. Table 4-2 also shows the depth for each site and whether the site was located in a MPA or KEF for ease of reference.

A total abundance of 293 individuals (ranging from 0 to 57 individuals per site), with a total taxa richness of 47 families (ranging from 0 to 14 families per site) were recorded during the infauna survey (see Table 4-2and Appendix E). Considering that 17 sites were sampled, these numbers are considered to be very low. Taxa diversity was also low at all sites and Shannon diversity ranged from 0 to 2.4 per site.

Table 4-2 Infauna abundance, richness and diversity at each site (based on standardised volume of 0.1 m^3)

Site	0	1	2	3	5	6	7	8	10	12	13	14	15	16	17	18	19
Total Abundance	8	14	5	30	3	6	1	8	3	22	57	37	0	31	28	15	25

* Richness data cannot be standardised and is per original volume

**Shannon diversity is displayed to 2 decimal places.

A summary of the abundance and richness of individual infauna phylum identified during the infauna survey is presented in Table 4-3. Annelida were the most abundant phylum (142 individuals recorded over all sites) and also contained the most families (21 families identified within this phylum). Arthropoda were the next most abundant phylum (with 89 individuals) and richness for this group was also higher than most (16 families). The total abundance of Echinodermata (22 individuals over 17 sites) and Sipuncula (35 individuals over 17 sites) were low but considerably higher than all other taxa identified with abundances ranging from just one to three individuals over 17 sampling sites. Total richness for all phylum apart from Annelida and Arthropoda were also low and ranged from just one to four families being identified.

Table 4-3 Abundance and richness of each infauna phylum identified

Phylum	Total Infauna Abundance	Total Taxa (Family) Richness
Annelida	142	21
Arthropoda	89	16
Chordata	3	2
Echinodermata	22	4
Mollusca	1	1
Nemertia	1	1
Sipuncula	35	2
Total	**293**	**47**

Figure 4-38 to Figure 4-40 show the total abundance, taxa richness and Shannon diversity at each site. As there was no spatial or temporal replication of samples within sites, no estimation of error can be provided.

Total infauna abundance was highest at Site 13 (57 individuals) and taxa richness was also highest at this site. Site 13 is located in water depths of 261 m and is not located within an AMP or KEF. Sites 3, 14, 16, 17 and 19 also had relatively high abundance (compared to that at many other sampling sites) ranging from 25 to 37 individuals (Figure 4-38). Depths at these five sites were extremely variable and ranged from 125 m to 351 m. Three of these sites were located within a KEF and none in an AMP. No infauna was recorded from the shell material submitted for Site 15. Abundance was very low, below 10 individuals, at Sites 0, 2, 5, 6, 7, 8 and 10. Water depth at these sites was typically much deeper, ranging from 329 to 428 m. Four of these sites were located within an AMP and six within a KEF.

The patterns seen for taxa richness tended to mirror the infauna abundance patterns (i.e. sites with higher abundance tended to have a higher taxa richness) (Figure 4-39). The same was true for infauna diversity, which generally mirrored patterns in abundance and richness (Figure 4-40).

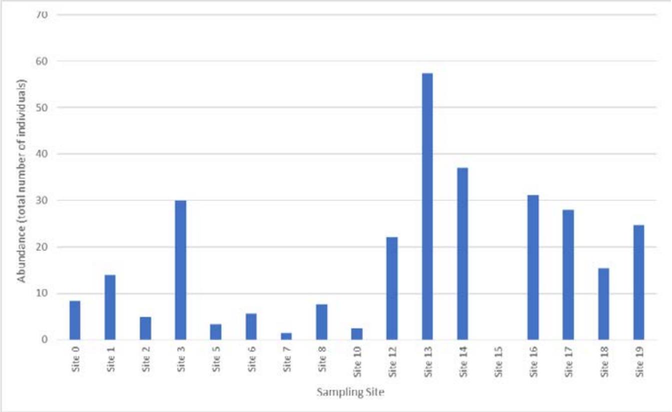

Figure 4-38 Infauna abundance (total number of individuals recorded) at each sampling site

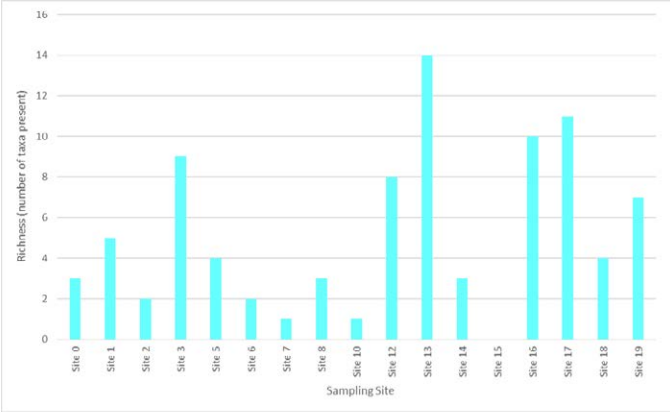

Figure 4-39 Infauna richness (total number of taxa recorded) at each sampling site

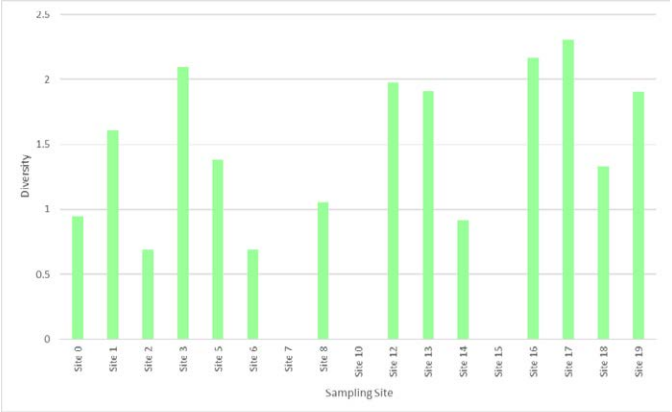

Figure 4-40 Infauna diversity (Shannon Diversity Index) at each sampling site

4.4.1.2 Multivariate Analysis

Sediment Characteristics

Sediment particle size distribution has been described in Section 4.3.6. Particle size distribution is variable between sites with the following noted in relation to smaller size classes.

- Sites 0, 5, 12 and 14 have lower proportions of sand and higher proportions of silt in comparison to all other sites.
- Sites 6, 7 and 18 have no, or very little, silt.
- Sites 0, 5, 12, 13, 14 and 16 have the highest proportions of clay.
- No PSD analysis was undertaken for Site 15.

Shade Plot

The shade plot below (Figure 4-41) lists the 25 most important infauna taxa present and shows their relative abundance (darker shading = more abundant), grouped by site. The plot is more useful as a baseline list of which infauna families are present, as there is too low an abundance and diversity to be able to interpret discernible patterns between sites.

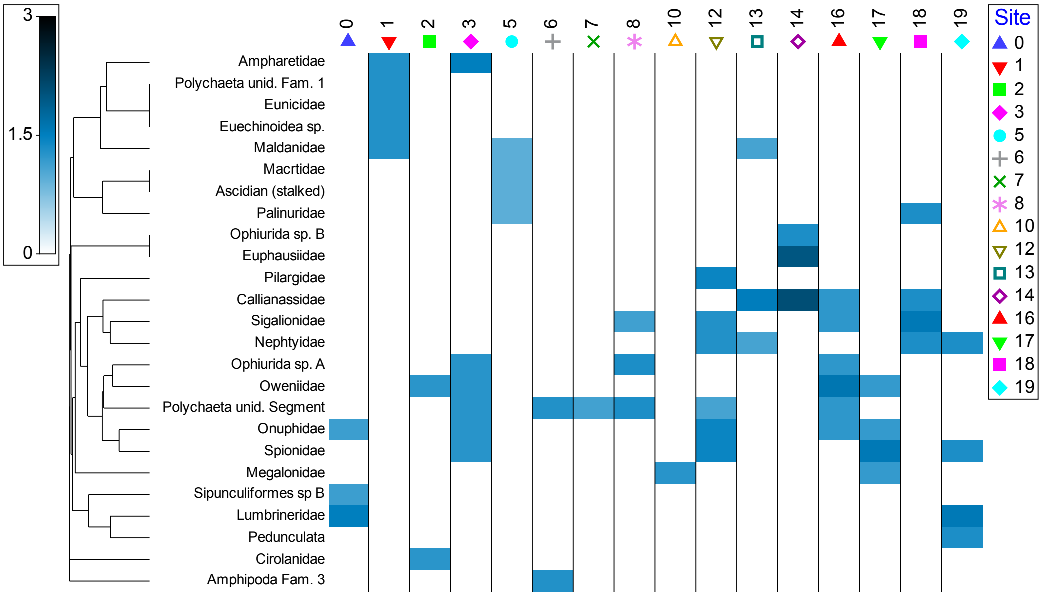

Figure 4-41 Shade plot showing the distribution of infauna families by site

Multi-dimensional Scaling

Multi-dimensional scaling (nMDS) plots of the fourth square root transformed infauna abundance data and displayed by various factors are shown in Figure 4-42 to Figure 4-49. In MDS plots, sites which are more similar to each other are grouped more closely together. A 2D stress level of 0.06 shows that the nMDS plots are a good representation of the underlying data. In general, no strong or definitive grouping of any sites based on the eight factors analysed by MDS were seen, indicating variation amongst the individual sites, however, the low infauna abundance and sampling approach should be acknowledged when interpreting the MDS plots. A summary of the patterns shown in the nMDS plots when displayed by the various factors is outlined in Table 4-4.

Table 4-4 Summary of patterns seen in MDS plots

Displayed by Factor	Figure	Potential Patterns
Site	Figure 4-42	Sites 6 and 7 were more similar to each other but there were no other discernible patterns seen between sites. Sites located closer together spatially were not necessarily similar to each other in terms of their infauna assemblages.
Depth	Figure 4-43	There was a slight tendency sites with depths below 250 m to occur more closely together, in comparison to sites located at depths between 250 m and 450 m. However, no strong patterns were detected between depth.
Marine Park	Figure 4-44	There was a slight grouping of sites that were located within the Kimberly Marine Park, the Argo-Rowley Terrace Marine Park (2 of 3 sites only) and those sites not located in a Marine Park. As all Marine Park Zones were classed as Multiple Use, no further information was gained from this Factor.
Marine Park Zone	Figure 4-45	
Key Ecological Features	Figure 4-46	No discernible patterns were seen between sites whether they were in an area defined as a KEF or not.
% Clay	Figure 4-47	There was a slight grouping of sites with a lower % of clay (6-20%) in comparison to sites with higher % of clay (21-50%).
% Silt	Figure 4-48	There was a slight grouping of sites with lower % of silt (6-10%).
% Sand	Figure 4-49	No discernible patterns could be seen.

5 Discussion

Sample sites were selected from the preliminary habitat map that represented both the expected seabed substrate and bedform type along the pipeline route, but also at sites with predicted more complex seabed features (mounds, scarps, harder substrates). Sample sites were also strategically located within areas where the proposed pipeline route intersects with AMPs or KEFs to determine if the environmental values associated with these areas are present or absent along the pipeline route.

Seabed imagery collected along the pipeline route is generally aligned with the interpretation of the geophysical data in the preliminary habitat map. The geophysical data is considered a good predictor of seabed substrate type and bedform. Differences between the interpretation of the geophysical data, the seabed imagery and sediment samples may be a result of scale differences. Larger bedforms such as sand waves are hard to accurately detect from the seabed imagery, with a field of view generally less than 5 m. This may result in the classification of waves/ripples superimposed on the larger bedform. Additionally, the gridding size of the bathymetry data (5 m) means smaller features (ripples) were only identifiable in the backscatter data when constructing the preliminary habitat map. The ability to detect these smaller features from the backscatter data depends on the scale of the features and the incidence angle, resulting in some minor discrepancies between the preliminary habitat map and the observations of smaller seabed features.

Sample sites (0 and 1) in the Kimberley Marine Park Multiple Use Zone did not identify any important foraging areas. The seabed was consistent with that expected on the North West Shelf. Sample sites (0, 1, 2, 3, 4 and 5) in the Continental Slope Demersal Fish Communities KEF did not identify an increase in the presence or diversity of demersal fishes. However, some species may have been disturbed by the presence of the camera system. Sample sites (7, 8, 9 and 10) in the Argo-Rowley Terrace AMP and Mermaid Reef and Commonwealth waters surrounding the Rowley Shoals KEF (Multiple Use Zone) did not identify any complex seabed features, increased species richness or resuspension of nutrients into the photic zone. Sample sites (17, 18 and 19) in the Ancient Coastline at 125 m Depth Contour KEF consisted of sand with varying proportions of silt and clay, with no evidence of rocky escarpments or harder seabed substrates.

The consolidated rubble identified at Sites 15 and 16 is in an area of more complex seabed features (scarps, mounds and scours) identified from the geophysical data. This was the only area identified from the field data containing harder seabed substrates along the proposed pipeline route. This harder substrate does not appear to support populations of epibenthic communities, with only solitary individuals identified from the seabed imagery. The geophysical data also suggests these areas of harder consolidated rubble are likely spatially confined (less than 1 km).

The dominant habitat type identified along the proposed pipeline route was unconsolidated soft sand, supporting various benthic infauna as evidenced by the observation of bioturbation and tracks at many sites. There was no discernable association between particular habitat types and geographical location or depth along the proposed pipeline route and given the absence of observations of habitat boundaries at sampling sites, habitat features outlined in the preliminary habitat map are considered to be accurate.

Results of water profiling and sampling indicate that the sites sampled were representative of the north-west offshore oceanic environment. Most of the physico-chemical characteristics of the water column were consistent between sites. Surface waters were generally well mixed to about 30 m at most sites; there is no apparent anthropogenic contamination of the waters along the proposed pipeline route, with most concentrations of potential contaminants below the 99% level of species protection DGVs from the Australian & New Zealand Guidelines for Fresh & Marine Water Quality (2018). The exception to this was the nutrient analyses (for TN and TP, NH_4, nitrite and nitrate), which were above the default guideline value for offshore waters at many of the sample locations (as per table 3.3.4 of ANZECC, 2000). Samples were unable to be delivered to the laboratory within the recommended holding times for nutrient analyses, due to the logistical nature of the survey. While it is possible the breach of recommended holding times may have affected nutrient results, there does not appear to be any obvious association between samples that exceeded holding times and elevations beyond guideline values.

Sediment quality results were below the DGV for sediment quality in the Australian & New Zealand Guidelines for Fresh & Marine Water Quality (2018) at most sites, except nickel at Site 6. While nickel concentrations are known to occur naturally beyond DGV in Pilbara regional waters (Stoddart et al., 2019), the elevated results from Site 6 are anomalous in the context of the proposed pipeline route. They may be caused by an anthropogenic source, possibly occurring while collecting samples. Where DGV are absent and concentrations of trace metals in sediments were able to be compared to other regional surveys (Gardline, 2009), or estimated natural background levels (DEC, 2006), the results from this survey were substantially lower. Given the low incidence of elevated concentration of contaminants over the extent of the proposed BTL, sediments are considered free from any anthropogenic contamination and are typical of open ocean environments off the west coast of Australia.

Benthic infauna abundance, taxa richness and diversity, as measured for individual sites, was low. The general patterns (but not values) between sites for infauna abundance, taxa richness and diversity were similar. The most abundant Phylum recorded during the survey were Annelida, with this Phylum also being the most taxa rich. Arthropoda were also relatively abundant and richness for this group was also higher than most others. The total abundance of the Phylum Echinodermata and Phylum Sipuncula were also relatively high.

There was considerable variability in infauna abundance, richness and diversity between sites. Multidimensional scaling showed the following patters:

- There was no grouping between sites with one exception being sites 6 and 7 which were very similar. Sites located closer together spatially were not necessarily similar to each other in terms of their infauna assemblages.
- There was a slight tendency for infauna assemblages at sites with depths below 250 m to occur more closely together (i.e. showing more similarity) in comparison to sites located at depths between 250 m and 450 m. However, no strong patterns in assemblages were detected for the factor depth. Initial data investigation showed that the sites with the highest infauna abundances occurred at depths ranging from 125 m to 351 m.
- When infauna assemblages were analysed according to sediment types (clay, silt and sand), there was a slight grouping of sites with a lower % of clay (6-20%) in comparison to sites with higher % of clay (21-50%). There was also a slight grouping of sites with lower % of silt (6-10%). However, no discernible patterns could be seen for % sand.
- When infauna assemblages were assessed in terms of their presence within an AMP, there was a slight grouping of sites that were located within the Kimberly Marine Park, sites in the Argo-Rowley Terrace Marine Park (2 of 3 sites only) and those sites not located in an AMP. Interestingly, sites with the highest abundance (and typically richness) were located outside of the AMPs. Four of the seven sites with the lowest infauna abundance (<10 individuals) and

richness occurred within AMPs (two in the Kimberly Marine Park and two in the Argo-Rowley Terrace Marine Park).

- No discernible patterns in infauna assemblages were detected between sites whether they were located in an area defined as a KEF or not. For example, three of the six sites with the highest infauna abundance (and typically corresponding richness) occurred in KEFs (one in the Continental Slope Demersal Fish KEF and two in the Ancient Coastline at 125m KEF). However, six of the seven sites with the lowest infauna abundance (< 10 individuals) and richness also occurred within a KEF (three in the Continental Slope Demersal Fish KEF and three in the Mermaid Reef KEF).

Most infauna sampling was undertaken in areas of unconsolidated soft sediment apart from Site 15 and 16 which were located in areas of more complex and consolidated habitat. The shell rubble collected from Site 15 did not contain infauna. However, soft sediment was able to be collected from Site 16, which was reported as being of a similar nature, and this site had relatively high infauna abundance and richness. The geophysical data suggests these areas of harder consolidated rubble are likely spatially confined (less than 1 km), which could account for soft sediment being able to be collected at Site 16 but not at Site 15.

The infauna investigation did not show any consistent differences in patterns of abundance, richness or diversity between sites with differing depths, or located within AMPs and/or KEFs. The statistical analysis undertaken for the current investigation is characterised by low abundance, richness and diversity of infauna assemblages. This feature is likely to be related to the depth of samples, as generally species diversity and richness are known to decrease with increasing depth, due to reduced sunlight and other optimum conditions for the productivity of infauna (Duxbury et al. 2003; Kropp et al. 2003).

Appendix B
Sampling Design Rationale

Sample Priority	Sample Site	Seabed Substrate	KEF or Marine Park	Reason for Site Selection	Depth (m)	Field Duplicate (FD)/Field Replicate (FR)	X Coordinate (Sample Site 0-6 = GDA Z51, 7-19 GDA Z50)	X Coordinate (Sample Site 0-6 = GDA Z51, 7-19 GDA Z50)
1	0	Coarse sand	KEF and AMP	Continental Slope Demersal Fish Communities KEF Kimberley Marine Park Spatial representation of the pipeline route and KEF	378	FD	315118.180	8331763.044
1	1	Fine sand-mud	KEF AMP	Continental Slope Demersal Fish Communities KEF Kimberley Marine Park Spatial representation of the pipeline route and KEF	349		302648.480	8313408.635
2	2	Large 2D Ripples	KEF	Continental Slope Demersal Fish Communities Ensure different seabed type in KEF is sampled	339		268950.462	8263767.183
2	3	Fine sand-mud	KEF	Continental Slope Demersal Fish Communities KEF Ensure different seabed type in KEF is sampled	356	FD	260738.068	8251358.479

Sample Priority	Sample Site	Seabed Substrate	KEF or Marine Park	Reason for Site Selection	Depth (m)	Field Duplicate (FD)/Field Replicate (FR)	X Coordinate (Sample Site 0-6 = GDA Z51, 7-19 GDA Z50)	X Coordinate (Sample Site 0-6 = GDA Z51, 7-19 GDA Z50)
2	4	Coarse sand	KEF	Continental Slope Demersal Fish Communities KEF	348		249088.284	8231056.756
2	5	Fine sand-mud	KEF	Continental Slope Demersal Fish Communities KEF	382	FR	236292.133	8209858.855
2	6	Coarse sand	KEF	Spatial coverage of pipeline route	434		206509.023	8159291.802
1	7	Medium 2D ripples	AMP KEF	Site is within Argo-Rowley Terrace Marine Park Mermaid Reef and Commonwealth waters surrounding Rowley Shoals KEF	377		782643.073	8087374.895
1	8	Coarse sand	AMP KEF	Argo-Rowley Terrace Marine Park Mermaid Reef and Commonwealth waters surrounding Rowley Shoals KEF	373		775964.986	8082667.771

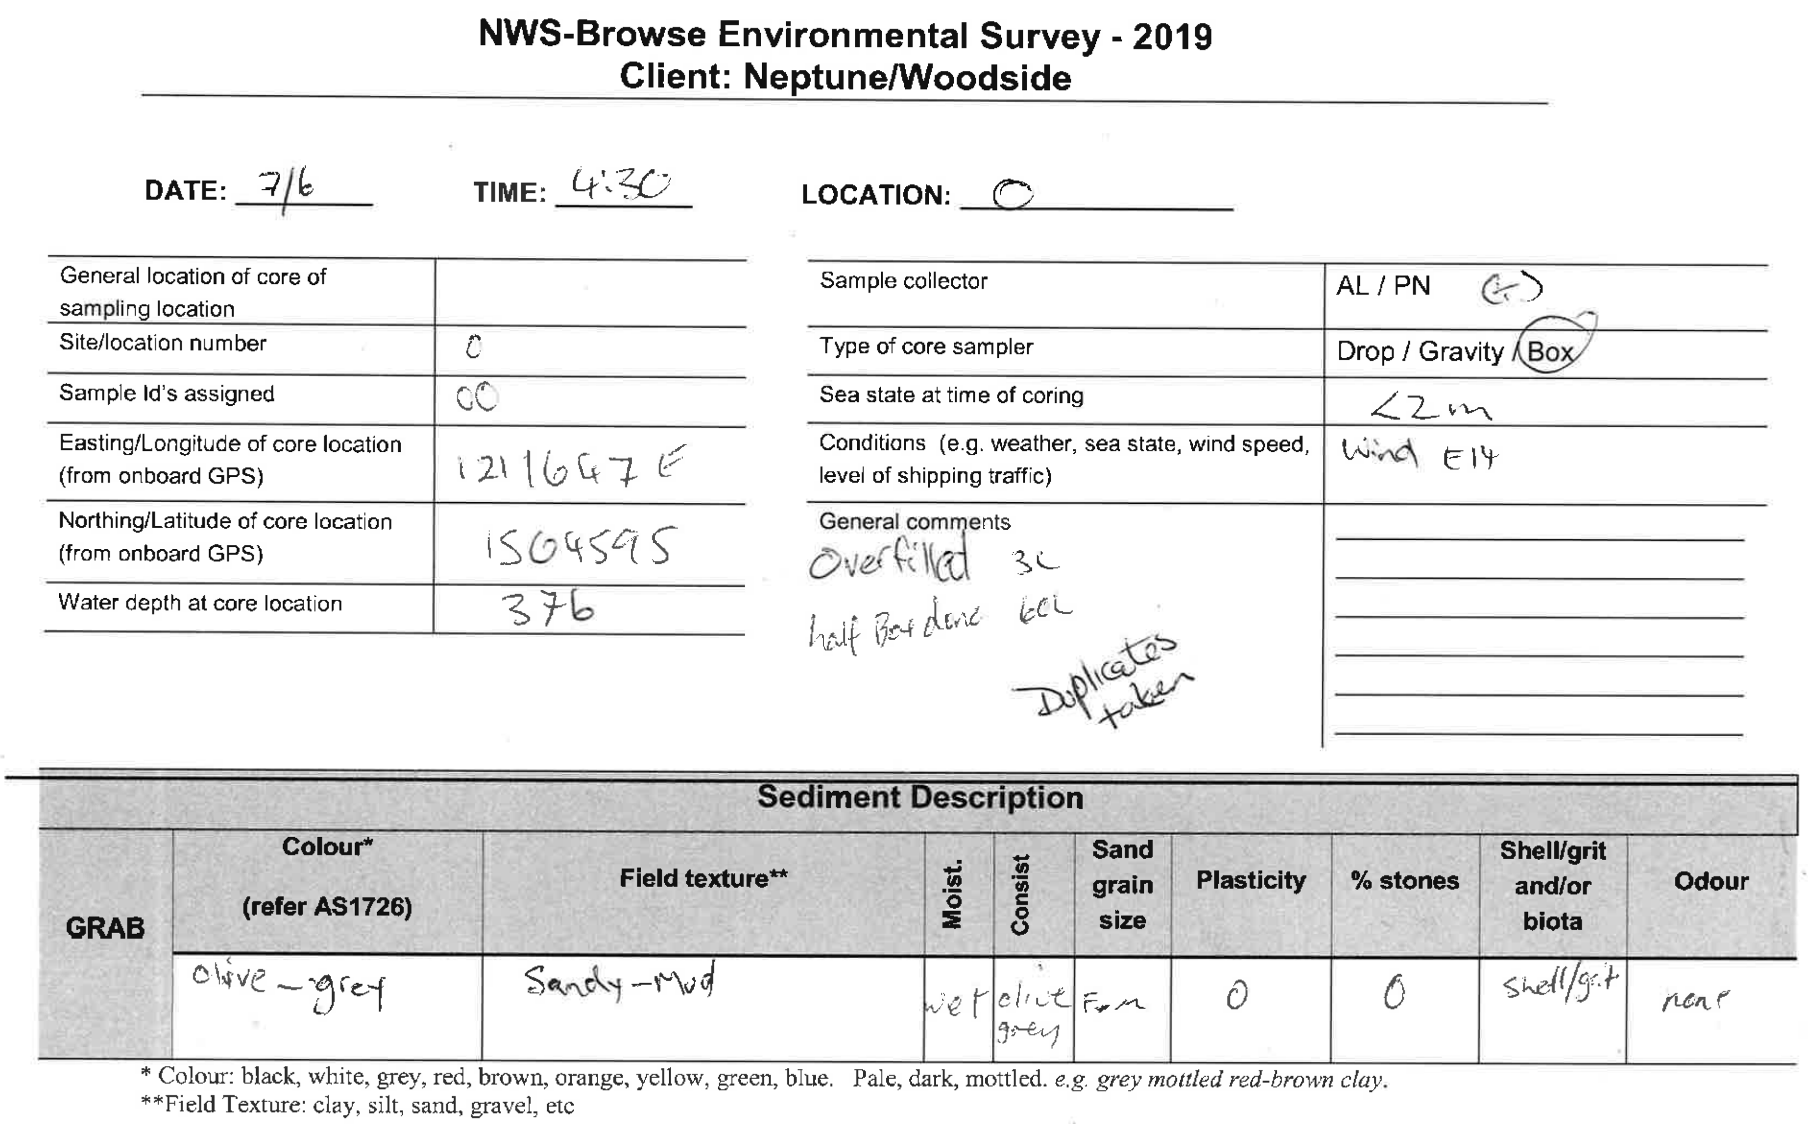
Sample Priority	Sample Site	Seabed Substrate	KEF or Marine Park	Reason for Site Selection	Depth (m)	Field Duplicate (FD)/Field Replicate (FR)	X Coordinate (Sample Site 0-6 = GDA Z51, 7-19 GDA Z50)	X Coordinate (Sample Site 0-6 = GDA Z51, 7-19 GDA Z50)
1	9	Medium 2D sand waves	AMP KEF	Argo-Rowley Terrace Marine Park Mermaid Reef and Commonwealth waters surrounding Rowley Shoals KEF	328	FR	733024.695	8046668.013
1	10	Coarse sand	AMP KEF	Argo-Rowley Terrace Marine Park Mermaid Reef and Commonwealth waters surrounding Rowley Shoals KEF	331		724509.125	8047096.470
3	11	Coarse sand		Potential site for hard substrate Potential for Increased species richness	267		667109.278	8001846.750
3	12	Coarse sand		Spatial coverage of pipeline route	268		557905.909	7930336.135
2	13	Sloped terrain scarp		Area of more complex seabed features	267		505237.135	7895811.563
3	14	Irregular 2D ripples		Coverage of variation of seabed substrate across the pipeline route	225		482387.779	7884252.744

Sample Priority	Sample Site	Seabed Substrate	KEF or Marine Park	Reason for Site Selection	Depth (m)	Field Duplicate (FD)/Field Replicate (FR)	X Coordinate (Sample Site 0-6 = GDA Z51, 7-19 GDA Z50)	X Coordinate (Sample Site 0-6 = GDA Z51, 7-19 GDA Z50)
2	15	Mound		Area of more complex seabed features	189		467787.611	7876922.289
3	16	Irregular 3D Ripples		Coverage of variation of seabed substrate across the pipeline route	197		443720.798	7876108.698
2	17	Fine sand-mud	KEF	Ancient Coastline at 125 m Depth Contour KEF	136		431325.375	7857652.669
2	18	Coarse sand	KEF	Area of more complex seabed features	131		415897.490	7849425.434
2	19	Fine sand-mud	KEF	Coverage of seabed substrate types within the Ancient Coastline at 125 m Depth Contour KEF	128		408199.977	7840088.869

Appendix C Survey Events

Dates	Sampling/Survey Events	Sites
9-Mar-19 to 12-Mar-19	Vessel mobilisation in Exmouth	NA
13-Mar-19	Drill and survey test	NA
14-Mar-19 to 15-Mar-19	Drop camera survey	18, 17 and 16
16-Mar-19	CPTs	NA
17-Mar-19	CPT and water quality sampling	17 and 18
18-Mar-19 to 19-Mar-19	Transit to Dampier and winch repair	NA
20-Mar-19 to 31-Mar-19	On standby while tropical cyclone Veronica passes	NA
1-Apr-19	Transit to sampling site	NA
2-Apr-19 to 5-Apr-19	Drop camera and water quality sampling	14, 15, 16 and 19
7-Apr-19 to 10-Apr-19	Servicing and crew change in Exmouth	NA
11-Apr-19 to 2-May-19	CPTs and crew change in Broome	NA
3-May-19 to 14-May-19	Piston coring, weather standby	NA
15-May-19 to 19-May-19	Sediment sampling	12, 19, 16, 17 and 18
20-May-19 to 21-May-19	Transit to Exmouth and IMS inspection	NA
22-May-19	Piston coring	NA
23-May-19	Sediment sampling	11, 13 and 14
24-May-19 to 6-Jun-19	Piston coring, weather standby and crew change in Broome	NA
7-Jun-19 to 10-Jun-19	Sediment sampling	0, 1, 2, 3, 4, 5, 6, 7, 8, 9 and 10

Appendix D Field Sheets



NWS-Browse Environmental Survey - 2019

Appendix F Laboratory Reports

ALS Environmental

CERTIFICATE OF ANALYSIS

Work Order : **EP1902492**
Amendment : **1**
Client : **WorleyParsons Services Pty Ltd**
Contact : MR PAUL NICHOLS
Address : LEVEL 4, 600 MURRAY STREET
WEST PERTH WA, AUSTRALIA 6005
Telephone : +61 08 9278 8111
Project : 401012-02648
Order number : 401012-02648
C-O-C number : ----
Sampler : Brendan Hirniak
Site : ----
Quote number : EP/618/18 V2
No. of samples received : 6
No. of samples analysed : 6

Page : 1 of 9
Laboratory : Environmental Division Perth
Contact : Marnie Thomsett
Address : 26 Rigali Way Wangara WA Australia 6065
Telephone : 08 9406 1311
Date Samples Received : 19-Mar-2019 08:00
Date Analysis Commenced : 20-Mar-2019
Issue Date : 01-Apr-2019 12:14

Accreditation No. 825
Accredited for compliance with
ISO/IEC 17025 - Testing

This report supersedes any previous report(s) with this reference. Results apply to the sample(s) as submitted. This document shall not be reproduced, except in full.

This Certificate of Analysis contains the following information:

- General Comments
- Analytical Results
- Surrogate Control Limits

Additional information pertinent to this report will be found in the following separate attachments: Quality Control Report, QA/QC Compliance Assessment to assist with Quality Review and Sample Receipt Notification.

Signatories

This document has been electronically signed by the authorized signatories below. Electronic signing is carried out in compliance with procedures specified in 21 CFR Part 11.

Signatories	*Position*	*Accreditation Category*
Canhuang Ke	Inorganics Supervisor	Perth Inorganics, Wangara, WA
David Viner	SENIOR LAB TECH	Perth Organics, Wangara, WA
Efua Wilson	Metals Chemist	Perth Inorganics, Wangara, WA
Ivan Taylor	Analyst	Sydney Inorganics, Smithfield, NSW
Mark Kinnin	Laboratory Technician	Perth Inorganics, Wangara, WA

Work Order : EP1902492 Amendment 1
Client : WorleyParsons Services Pty Ltd
Project : 401012-02648

General Comments

The analytical procedures used by the Environmental Division have been developed from established internationally recognized procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are employed in the absence of documented standards or by client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

When sampling time information is not provided by the client, sampling dates are shown without a time component. In these instances, the time component has been assumed by the laboratory for processing purposes.

Where a result is required to meet compliance limits the associated uncertainty must be considered. Refer to the ALS Contact for details.

Key : CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society.
LOR = Limit of reporting
^ = This result is computed from individual analyte detections at or above the level of reporting
ø = ALS is not NATA accredited for these tests.
~ = Indicates an estimated value.

- EG093 conducted by ALS Sydney, NATA accreditation no. 825, site no 10911.
- Benzo(a)pyrene Toxicity Equivalent Quotient (TEQ) per the NEPM (2013) is the sum total of the concentration of the eight carcinogenic PAHs multiplied by their Toxicity Equivalence Factor (TEF) relative to Benzo(a)pyrene. TEF values are provided in brackets as follows: Benz(a)anthracene (0.1), Chrysene (0.01), Benzo(b+j) & Benzo(k)fluoranthene (0.1), Benzo(a)pyrene (1.0), Indeno(1.2.3.cd)pyrene (0.1), Dibenz(a.h)anthracene (1.0), Benzo(g.h.i)perylene (0.01). Less than LOR results for 'TEQ Zero' are treated as zero.
- Amendment (01/04/2019): This report has been amended as a result of a change to the client office. All analysis results are as per the previous report.

Contact : Marnie Thomsett
Address : 26 Rigali Way Wangara WA Australia 6065
Telephone : 08 9406 1311
Date Samples Received : 08-Apr-2019 14:40
Date Analysis Commenced : 09-Apr-2019
Issue Date : 24-Apr-2019 11:46

Accreditation No. 825
Accredited for compliance with
ISO/IEC 17025 - Testing

This report supersedes any previous report(s) with this reference. Results apply to the sample(s) as submitted. This document shall not be reproduced, except in full.

This Certificate of Analysis contains the following information:

- General Comments
- Analytical Results
- Surrogate Control Limits

Additional information pertinent to this report will be found in the following separate attachments: Quality Control Report, QA/QC Compliance Assessment to assist with Quality Review and Sample Receipt Notification.

Signatories

This document has been electronically signed by the authorized signatories below. Electronic signing is carried out in compliance with procedures specified in 21 CFR Part 11.

Signatories	*Position*	*Accreditation Category*
Canhuang Ke	Inorganics Supervisor	Perth Inorganics, Wangara, WA
Celine Conceicao	Senior Spectroscopist	Sydney Inorganics, Smithfield, NSW
David Viner	SENIOR LAB TECH	Perth Organics, Wangara, WA
Mark Kinnin	Laboratory Technician	Perth Inorganics, Wangara, WA

Project : 401012-02648

General Comments

The analytical procedures used by the Environmental Division have been developed from established internationally recognized procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are employed in the absence of documented standards or by client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

When sampling time information is not provided by the client, sampling dates are shown without a time component. In these instances, the time component has been assumed by the laboratory for processing purposes.

Where a result is required to meet compliance limits the associated uncertainty must be considered. Refer to the ALS Contact for details.

Key : CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society.
LOR = Limit of reporting
^ = This result is computed from individual analyte detections at or above the level of reporting
ø = ALS is not NATA accredited for these tests.
~ = Indicates an estimated value.

- ORC Metals analysis conducted by ALS Sydney, NATA accreditation no. 825, site no 10911.
- Benzo(a)pyrene Toxicity Equivalent Quotient (TEQ) per the NEPM (2013) is the sum total of the concentration of the eight carcinogenic PAHs multiplied by their Toxicity Equivalence Factor (TEF) relative to Benzo(a)pyrene. TEF values are provided in brackets as follows: Benz(a)anthracene (0.1), Chrysene (0.01), Benzo(b+j) & Benzo(k)fluoranthene (0.1), Benzo(a)pyrene (1.0), Indeno(1.2.3.cd)pyrene (0.1), Dibenz(a.h)anthracene (1.0), Benzo(g.h.i)perylene (0.01). Less than LOR results for 'TEQ Zero' are treated as zero.
- EG093: Samples containing high levels of sulfate may precipitate barium under the acidic conditions of this method and may therefore bias results low.

Appendix G Water Quality Data QA

Temperature

The temperature and depth profiles of Sites 5 and 5 Repeat show a similar trend of decrease in temperature with depth.

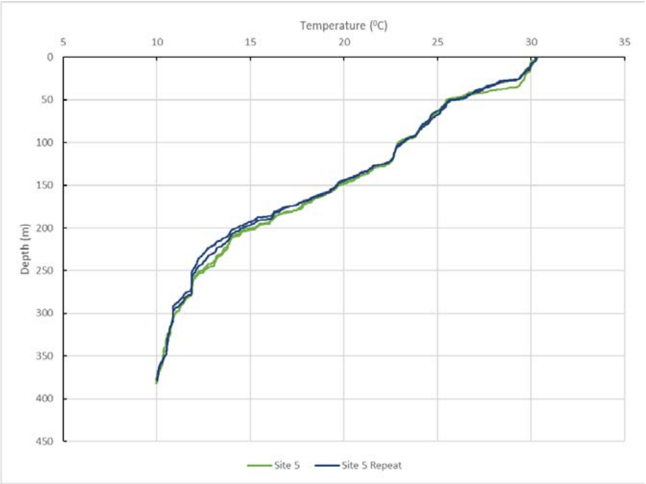

Figure E-1: Temperature (ºC) depth (m) profile at sampling Sites 5 and 5 Repeat

The temperature and depth profiles of Sites 9 and 9 Repeat show a similar trend of decrease in temperature with depth.

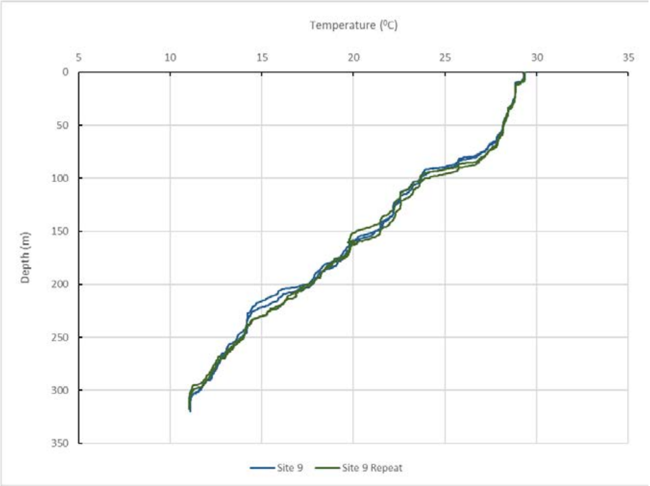

Figure E-2: Temperature (ºC) depth (m) profile at sampling Sites 9 and 9 Repeat

Conductivity

The conductivity over depth profiles of Sites 5 and 5 Repeat show a similar trend of decrease with depth; both profiles compare well.

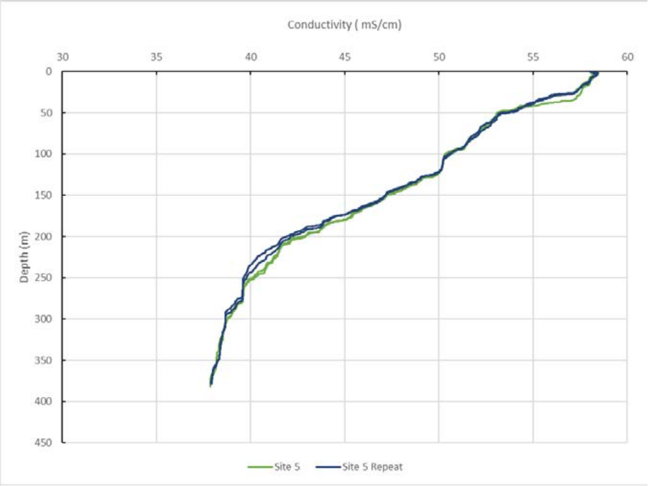

Figure E-3: Conductivity (mS/cm) depth (m) profile at sampling Sites 5 and 5 Repeat

The conductivity over depth profiles of Sites 9 and 9 Repeat show a similar trend of decrease with depth; both profiles compare well.

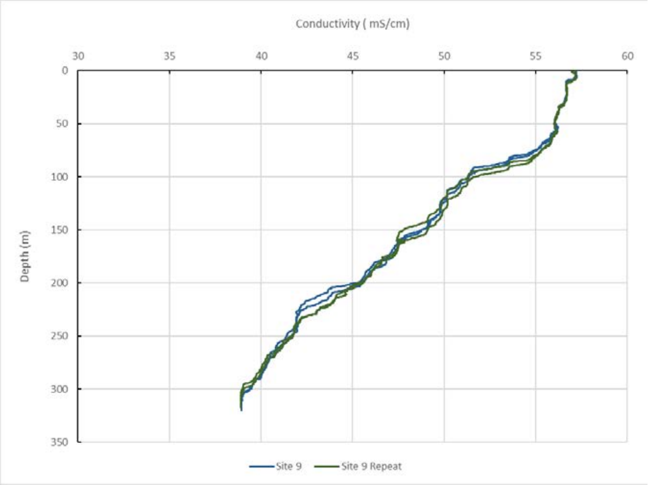

Figure E-4: Conductivity (mS/cm) depth (m) profile at sampling sites 9 and 9 Repeat

Salinity

The salinity over depth profiles for Site 5 and 5 Repeat compare well.

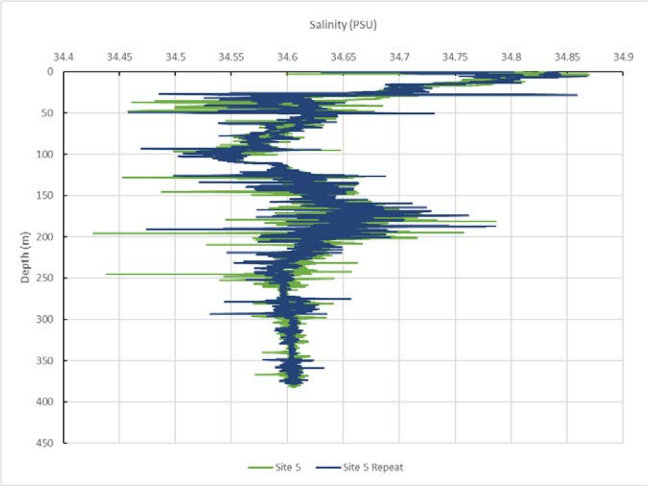

Figure E-5: Salinity (PSU) depth (m) profile at sampling Sites 5 and 5 Repeat

The salinity over depth profile for Sites 9 and 9 Repeat compare well.

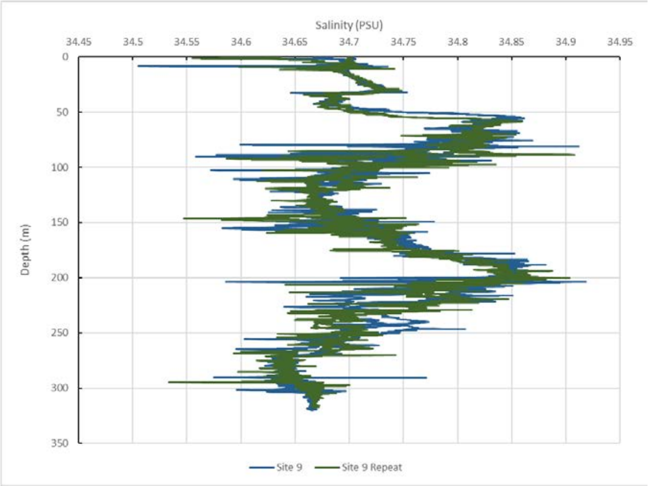

Figure E-6: Salinity (PSU) depth (m) profile at sampling Sites 9 and 9 Repeat

Turbidity

The turbidity over depth profiles for Sites 5 and 5 Repeat show a consistent trend with depth, as both profiles fluctuate around the 0 NTU range and compare well.

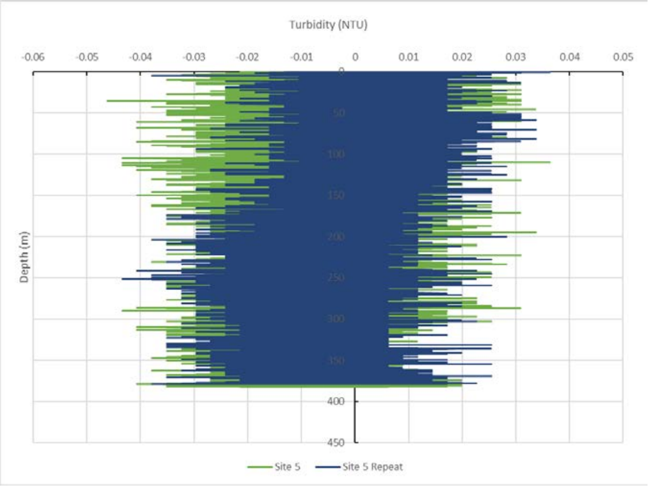

Figure E-7: Turbidity (NTU) depth (m) profile at sampling Sites 5 and 5 Repeat

The turbidity over depth profile for Sites 9 and 9 Repeat show consistent trends with depth. Site 9 is about 1.3 NTU and 9 Repeat 1.08 NTU over depth. Though these profiles appear different, the difference in NTU is negligible and they are considered to compare well.

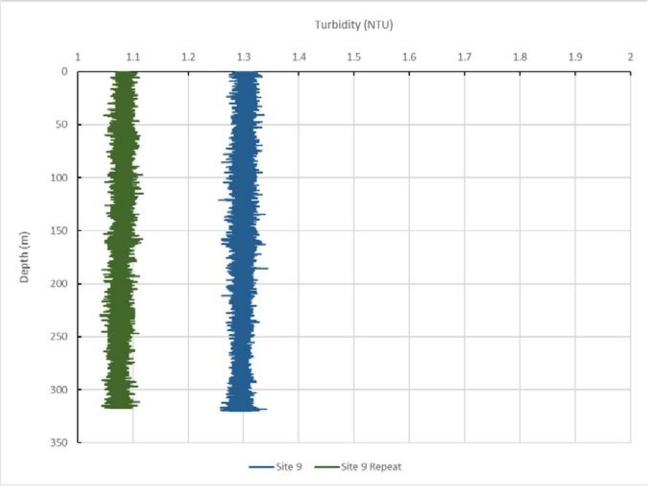

Figure E-8: Turbidity (NTU) depth (m) profile at sampling Sites 9 and 9 Repeat

Dissolved Oxygen

Both profiles for Sites 5 and 5 Repeat compare well, showing a similar trend of decrease with depth.

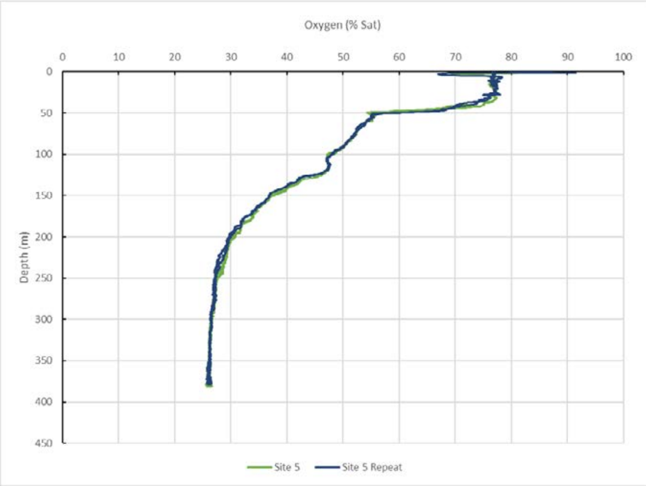

Figure E-9: Oxygen (% Sat) depth (m) profile at sampling Sites 5 and 5 Repeat

Both profiles for Sites 9 and 9 Repeat compare well, showing a similar trend of decrease with depth.

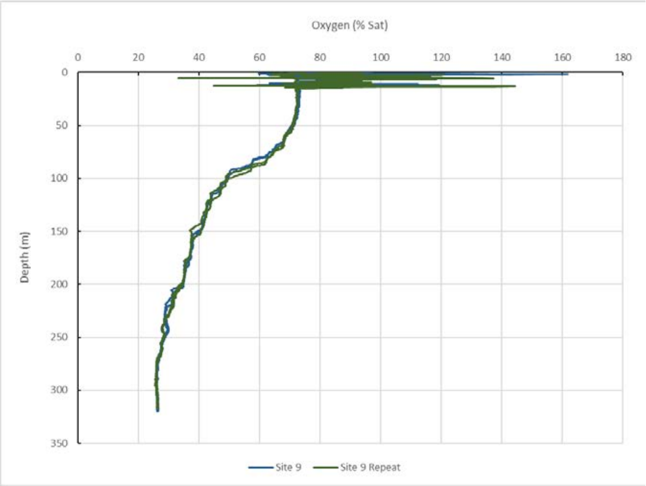

Figure E-10: Oxygen (% Sat) depth (m) profile at sampling Sites 9 and 9 Repeat

pH

The pH over depth profiles for Sites 5 and 5 Repeat show fairly similar trends, except for the initial drop from 0 to about 150 m, where Site 5 started off with a pH of 7.3 and Site 5 Repeat with a pH of 8.3.

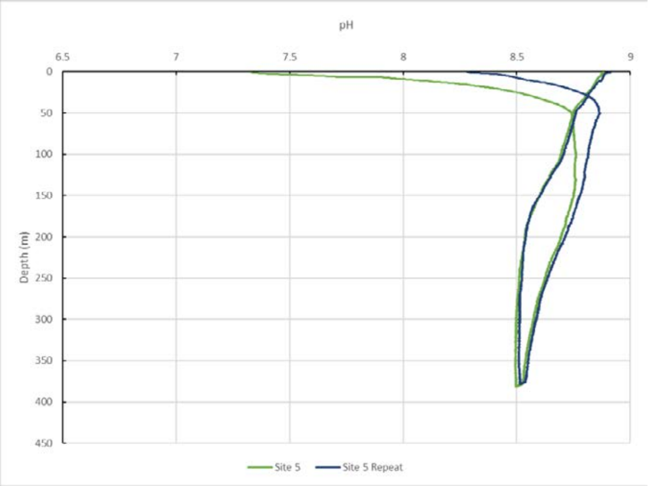

Figure E-11: pH depth (m) profile at sampling Sites 5 and 5 Repeat

The pH over depth profiles for Sites 9 and 9 Repeat show fairly similar trends, except for the initial drop from 0 to about 150 m where Site 9 started off with a pH of 7.3 and Site 9 Repeat with a pH of 8.6.

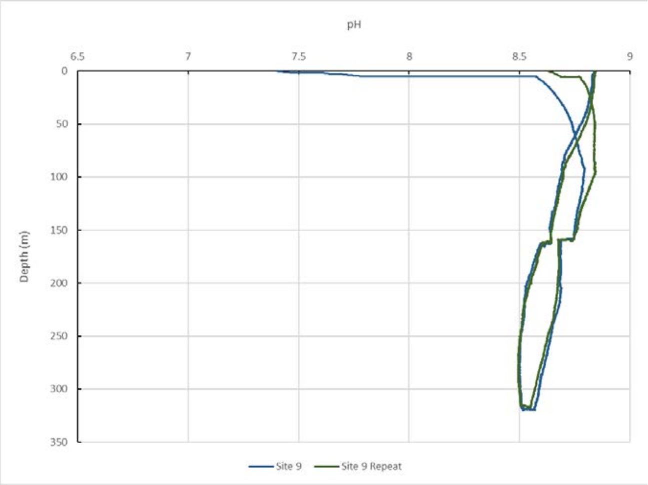

Figure E-12: pH depth (m) profile at sampling Sites 9 and 9 Repeat

Fluorescence

The fluorescence over depth profiles for Sites 5 and 5 Repeat compare well, showing a similar trend of increase with depth.

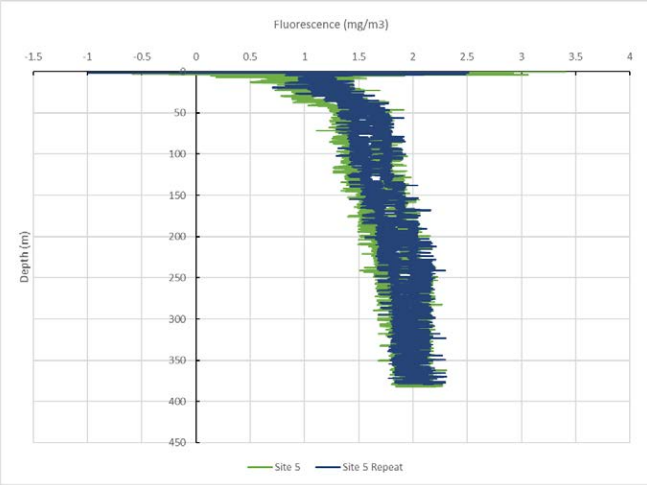

Figure E-13: Fluorescence (mg/m^3) depth (m) profile at sampling Sites 5 and 5 Repeat

The fluorescence over depth profiles for Sites 9 and 9 Repeat compare well, showing a similar trend of increase with depth.

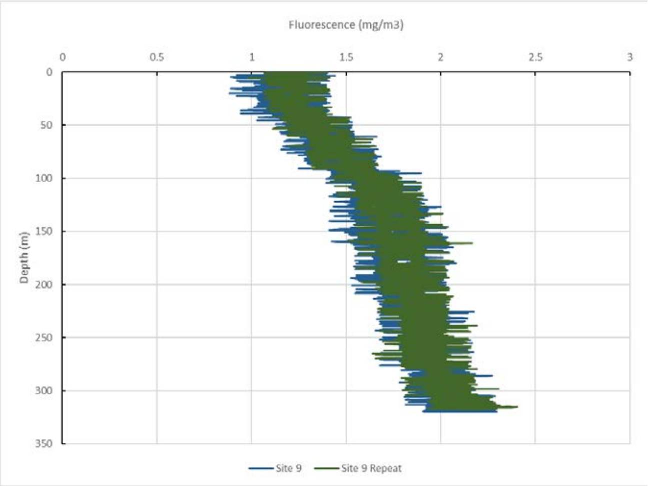

Figure E-14: Fluorescence (mg/m3) depth (m) profile at sampling sites 9 and 9 Repeat

Trace Metals

A total of 24 QA/QC samples were collected to compare with the primary samples to determine intra-lab and field variability in the data (i.e. duplicates and replicates). The derived RPD for each analysis are presented in Table E-1. In accordance with the NAGD (for all intents and purposes), the absolute value of the RPD should not be more than ±35% for duplicate and ±50% for replicate for each comparison. Values in sites that were highlighted in blue were half of their LoR for comparison of RPD. RPD highlighted in red were over their respective value.

Most of the RPD values were below the ±35 and ±50% for duplicates and replicates respectively, except:

- Aluminium for Site 0 surface, mid and bottom of 153%, 67% and 82% respectively
- Barium for Site 5 surface of 80%
- Chromium for Site 3 mid, Site 9 surface and mid of 67%, -95% and 105% respectively
- Copper for Site 3 surface, bottom and Site 9 mid of 100%, -100% and -67% respectively
- Iron for Site 0 bottom, Site 3 surface and bottom, Site 5 mid and Site 9 surface and mid of -82%, 67%, -82%, -95%, -53% and 126% respectively
- Lead for Site 3 surface and Site 9 mid of 67% and -100% respectively
- Vanadium for Site 0 surface, Site 3 surface, mid, Sites 5 and 9 bottom of -111%, 68%, 47%, -52% and -55% respectively.

Nutrients, Ammonia, and Nitrite and Nitrate

As part of the field sampling program, 24 field QA/QC samples were collected for Total Nitrogen and Total Phosphorous, NH_4, and Nitrite and Nitrate analysis and comparisons to primary samples to determine intra-lab and field variability in the data (i.e. duplicate and replicate). The derived RPD for each analysis are presented in Table E-2. Most of the samples were below the ±35% and ±50% for duplicates and replicates respectively, except Sites 0 and 0 Duplicate surface sample for Nitrite and Nitrate with RPD of 40%, and Sites 5 and 5 Repeat where the mid water sample for NH4 had an RPD of 188% (highlighted in red).

Total Recoverable Hydrocarbons and Polycyclic Aromatic Hydrocarbons

The 24 field QA/QC samples collected for TRH and PAH analysis were all below the laboratory LoR, thus RPD for all samples is 0%.

Appendix H Sediment Data QA

A total of eight QA/QC samples were collected to compare with the primary samples to determine intra-lab and field variability in the data (i.e. duplicates and replicates). Values in sites that were highlighted in blue were half of their LoR for comparison of RPD. RPDs highlighted in red were over their respective value.

Trace Metals

The derived RPDs for trace metals are presented in Table F-1. All comparisons were below the RPD of ±35% for duplicate and ±50% for replicate

Table F-1: RPD for trace metals

Particle Size Distribution

The derived RPDs for particle size distribution are presented in Table F-6. RPDs for Site 5 were all below ±50%. RPDs for Sites 0, 7 and 9 have PSD over ±35% and ±50% respectively; Site 0 for 75, 150, 300, 425 µm and sand of -67%, -91%, -100%, -120% and -43% respectively; Site 7 for 1180 µm and gravel of -40% and -67% respectively; and Site 9 for silt of 67%.

Table F-6: RPD for particle size distribution

		Location ID	Site 0	Site 0 Duplicate	RPD	Site 5	Site 5 Repeat	RPD	Site 7	Site 7 Duplicate	RPD	Site 9	Site 9 Repeat	RPD

Executive Summary

Coral communities at Scott Reef and the Rowley Shoals have experienced substantial change over the history of monitoring (1994–2017). Various disturbances – mass bleaching, cyclones and moderate bleaching – and their effects on coral communities are described, with differences in impact and recovery linked to local disturbance regimes, routine environmental conditions, variation in community composition and coral life history traits.

In 2016, heat stress and coral bleaching affected reefs worldwide, including those in north-western Australia. Heat stress in the region was the highest on record, but far higher at Scott Reef (16.5° C-weeks) than at the Rowley Shoals (5.8° C-weeks). The heat stress caused mass bleaching (> 70%) across Scott Reef, but only minor (< 10%) bleaching at most locations at the Rowley Shoals.

The 2016 mass bleaching devastated coral communities at Scott Reef, which had only recently recovered from mass bleaching in 1998. Both mass bleaching events had similar impacts, reducing coral cover in shallow water habitats (< 20 m) by approximately 75% and affecting all coral taxa; there was a similar pattern of susceptibility among taxa in both events, including those that had not yet recovered from the 1998 mass bleaching. In contrast, mass bleaching has not impacted the Rowley Shoals and the 2016 bleaching did not reduce mean cover at any of its three reefs.

Over more than two decades of impact and recovery, the coral communities at Scott Reef transitioned through four states indicative of their condition. The pre-bleaching and recovery states had a higher cover (> 45%) of hard and soft corals and an abundance of different coral taxa. The mass bleaching and post-bleaching states were the more degraded, with much lower coral cover (< 22%) and the absence of vulnerable taxa (e.g. soft corals, *Acropora*, *Isopora*, Pocilloporidae), including those providing food and shelter to fishes and other reef organisms. Smaller changes in community structure at the Rowley Shoals grouped into three periods, around local impacts and rapid recovery (< 5 years) from cyclones, all of which reflected a healthy reef system.

The recovery of Scott Reef following the 1998 mass bleaching was facilitated by its healthy fish stocks, high water quality and a decade (1999–2009) with few disturbances. Given comparable impacts in 1998 and 2016, a similar timeline for recovery (10–15 years) might be expected if the future water quality, fish stocks and disturbances regime were also similar. However, from 2010 impacts from bleaching and cyclones increased, and ongoing climate change is expected to cause further increases in heat stress and cyclone intensity. Recovery of Scott Reef will not follow a similar trajectory as after the 1998 mass bleaching if severe disturbances occur more frequently (< 10 years) – meaning communities will remain in more degraded states. Global increases in the severity of heat stress and cyclones are also likely to affect the Rowley Shoals. However, since 2010 there was a consistently high (> 40%) coral cover at the Rowley Shoals and its low level of degradation makes the reef system an important benchmark for assessing the condition of other coral reefs, locally and globally.

1. Introduction

Western Australia's coral reefs span more than 12,000 km of coastline and 20 degrees of latitude, ranging from tropical to temperate climates (Veron and Marsh 1988). The most diverse reefs are in the Kimberley region of north-western Australia (McKinney 2009; Richards et al. 2014), where the oceanic reef systems of Ashmore, Scott and the Rowley Shoals sit near the edge of the continental shelf, hundreds of kilometres from the mainland and from each other. The Scott (South Reef, North Reef, Seringapatam) and Rowley Shoals (Imperieuse, Clerke, Mermaid) reef systems have high water quality and relatively low fishing pressures (Halpern et al. 2015; Zinke et al. 2018; Gilmour et al. 2019). However, traditional fishing of shark fin, *Trochus* and sea cucumber still occurs at Scott Reef (Stacey 2007), and these targeted species are all overfished (Meekan et al. 2006; Bryce 2007).

Damaging waves generated by storms and cyclones have historically been the most common acute disturbance to coral reefs in the Kimberley region. Scott Reef and the Rowley Shoals are buffeted by waves from a westerly and south-westerly direction, particularly between November and April when monsoonal storms and cyclones are common (Berry and Marsh 1986; Bowman et al. 2010; Drost et al. 2017). However, heat stress during El Niño conditions is increasingly affecting these reefs (Hughes et al. 2017; Benthuysen et al. 2018; Gilmour et al. 2019). Heat stress has caused repeated bleaching of varying severity at Ashmore Reef, Scott Reef and the Rowleys Shoals. The Rowley Shoals has so far escaped mass bleaching (Gilmour et al. 2019) and Scott Reef has been worst affected, particularly during the global bleaching events in 1998 and 2016 (Gilmour et al. 2013b; Eakin et al. 2018; Gilmour et al. 2019).

Despite the isolation of Scott Reef and the loss of 80% of its corals, communities had largely recovered from the 1998 mass bleaching within 10–15 years (McKinney 2009; Gilmour et al. 2013b). The resilience of the system was attributed to high rates of growth and survival of corals over several generations, due to high water quality and healthy fish stocks. However, not all coral taxa had recovered and there was associated variation in impacts and recovery among communities across the reef system. Changes in coral communities at both Scott Reef and the Rowley Shoals were structured by a complex regime of disturbances over more than two decades, whose effects were mediated by local environmental conditions and expressed through the life history traits of dominant coral taxa. The complexity of these processes and the degradation of the world's reefs (Hughes 1994; Knowlton 2001; Jones et al. 2004) highlight the importance of large-scale, long-term, studies that provide insights into the processes underlying their maintenance or degradation. Long-term studies are particularly important at reef systems that have escaped chronic local pressures but experienced varying levels of heat stress and coral bleaching, as climate change emerges as the most immediate threat to the future of coral reef ecosystems.

Here, we describe the changes in coral communities at Scott Reef and the Rowley Shoals over 23 years, from 1994 to 2017. We document the impacts of mass bleaching, cyclones and moderate bleaching on coral communities and attribute differences in impact and recovery to local disturbance regimes, routine environmental conditions, variation in community composition and coral life history traits. We divide changes in community structure into states of increasing disturbance and degradation, describing the corresponding reductions in coral cover and taxa that contribute most to reef structure and the maintenance of associated organisms. These processes are considered in the context of the most recent heat stress (2016) and ongoing climate change.

2. Methods

2.1 Study sites

Scott Reef is a large atoll-like reef system on the edge of the continental shelf, 270 km from the mainland of north-western Australia and 400 km from the Rowley Shoals (**Figure 1a**). The system consists of South Reef, North Reef and Seringapatam Reef. Benthic communities and habitat conditions were studied at seven locations (**Figure 1b**) in the reef-slope habitat (6 m depth at Lowest Astronomical Tide [LAT]). Outer-slope locations were on the eastern side of South Reef (Outer South East), North Reef (Outer North East) and Seringapatam Reef (Outer Seringapatam). Inner-slope locations were adjacent to the West Hook (Inner South West) and East Hook (Inner South East) at South Reef, at the lagoon at South Reef (South Lagoon), and the channel between South and North Reef (Channel). At each location, three replicate sites were surveyed during each year up to 2016. From 2016, only the first site at each location was surveyed and additional sites established in the adjacent reef crest habitat (3 m LAT), and within the lagoon at North Reef and Seringapatam Reef (SRLGA, SRLGB, NL_M23A), in response to predicted mass bleaching.

The Rowley Shoals is a group of three isolated reef atolls, 260 km from the mainland of north-western Australia (**Figure 1a**). The system consists of Imperieuse Reef, Clerke Reef and Mermaid Reef; each separated by 30–40 km. Benthic communities were surveyed at long-term monitoring locations in the outer reef-slope habitat (6 m LAT) at each reef (RS1, RS2, S3; **Figure 1c**). At each location, three replicate sites were surveyed during each year up to 2016. From 2016, only the first site at each location was surveyed. In 2013, 2016 and 2017, additional sites were established in the adjacent reef crest habitat (3 m LAT) at each reef, and in the lagoon at Mermaid (M11, M12) and Clerke (C13, C20) reefs, for comparison among habitats and in response to predicted mass bleaching in 2016. These additional lagoon sites were located at the top (edge) and base (7 to 12 m) of isolated coral outcrops (bommies). Data collection at all sites followed the standard AIMS LTM methods (Jonker et al. 2008).

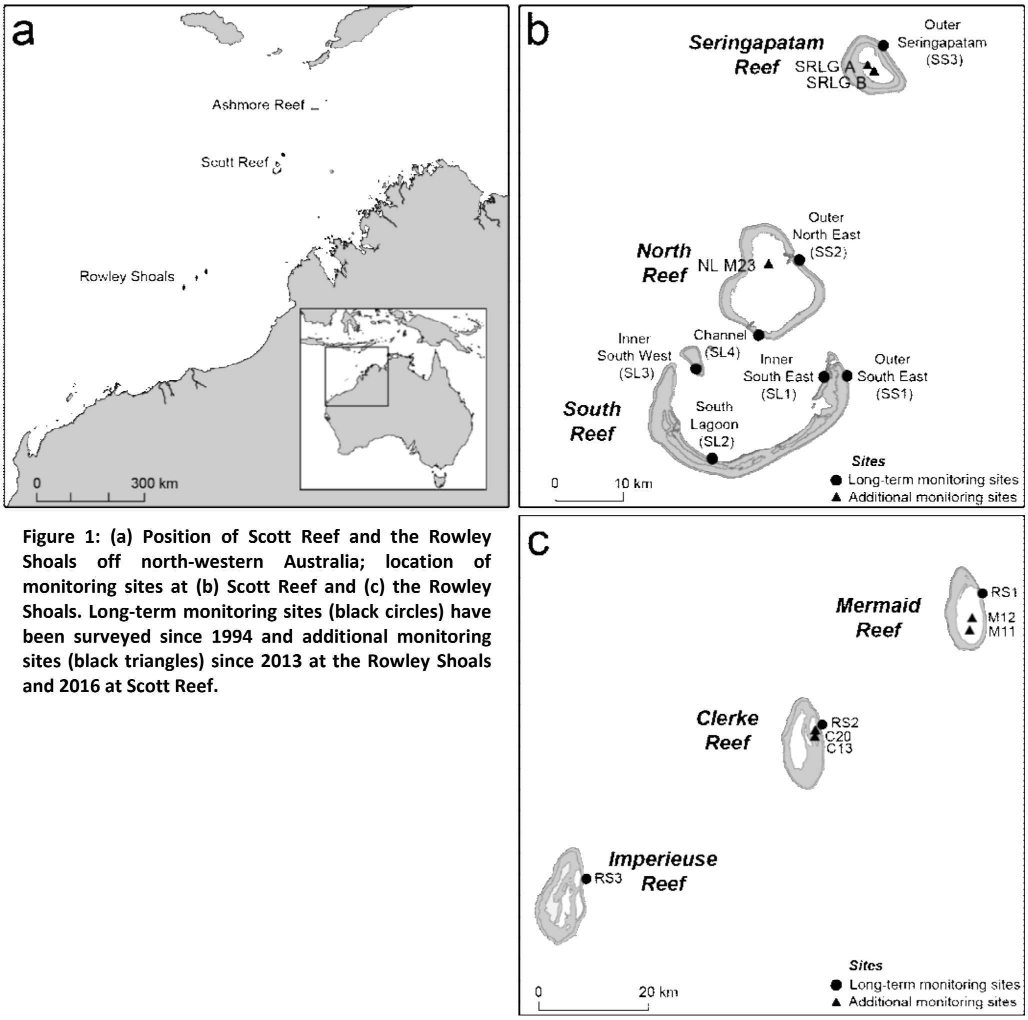

Figure 1: (a) Position of Scott Reef and the Rowley Shoals off north-western Australia; location of monitoring sites at (b) Scott Reef and (c) the Rowley Shoals. Long-term monitoring sites (black circles) have been surveyed since 1994 and additional monitoring sites (black triangles) since 2013 at the Rowley Shoals and 2016 at Scott Reef.

2.2 Benthic communities

2.2.1 Survey Methods

At each of the long-term monitoring locations (**Figure 1**), three replicate sites were separated by approximately 300 m, each consisting of 250 m of permanent transects marked at 10 m intervals. At Scott Reef, surveys were conducted annually between 1994 and 1999, and then in 2003, 2004, 2005, 2008, 2010, 2012, 2014, 2016 and 2017. In 2016, additional surveys were conducted in January, April and October 2016; before, during and after the mass bleaching. At the Rowley Shoals, surveys were conducted annually between 1995 and 1998, then in 2001, 2005, 2008, 2010, 2013, 2016 and 2017.

During each survey, a tape was laid along the permanent transect and images of the benthic community captured from a distance between 30 and 50 cm from the substrata. Images were analysed using point sampling technique and benthic groups identified to the lowest taxonomic resolution achievable by each observer (Jonker et al. 2008). These data were then divided among benthic groups according to taxa (i.e. family, genus) and growth form (encrusting, foliose, massive, branching) (**Table 1**). At Scott Reef, the six most abundant genera accounted for 80% of total hard coral cover. At the Rowley Shoals, the seven most abundant hard coral genera accounted for more than 75% percent of total hard coral cover. In instances where genera were rare (< 3% in all surveys) or difficult to distinguish, they were grouped to family or growth forms that distinguished their response to disturbances.

2.2.2 Statistical Analyses

Benthic communities were compared by multivariate analyses using the software PRIMER (Clarke and Warwick 2001). Percentage cover of each benthic group, at each site, location and year were transformed (Square root or Log + 1) to reduce the influence of dominant groups (e.g. crustose coralline algae) but to retain the major differences in community structure. Specific comparisons among communities in space or time were investigated by calculating Bray-Curtis measures of dissimilarity. Changes in community structure were illustrated using two-dimensional plots of non-metric multidimensional scaling (nMDS). The scale at which community structure varied spatially (sites) and temporally (years) was investigated using a cluster analysis and dendrograms, tested using the SIMPROF (5%) procedure in PRIMER. Over the entire survey period, there was considerable variation in community structure among the seven locations across the reef system, but little variation among the replicate sites within each location (**Appendix 1**). Consequently, data are presented at the location level throughout the Results, with associated variances derived from site replication.

2.3 Spatial and temporal variation in habitat conditions

2.3.1 Local variation in local environmental conditions at Scott Reef

Study sites within the reef slope habitat across the Scott Reef system experience different local environmental conditions. To explore the influence of local conditions on the community recovery following the 1998 mass bleaching, physical parameters predicted to have the greatest influence on community structure were quantified (**Table 2**). At the Rowley Shoals, these physical parameters have not been quantified, so equivalent comparisons cannot be made. The mean percentage cover of sand at each location was quantified along the permanent transects (250 m) during the study period (1994 to 2017) according to the AIMS LTM methods (Jonker et al. 2008). Comparative sedimentation rates were quantified using replicate ($n = 5$) sediment traps spaced at 10 m intervals along a permanent transect at each of the long-term study locations at South Reef and North Reef between July 2008 and February 2010. Sediment traps were constructed from cylindrical lengths (700 mm) of PVC tubing with an internal diameter of 110 mm, sealed at one end, and elevated above the bottom the substrata. Baffles within each trap consisted of seven 150 mm lengths of PVC tube with an internal diameter of 30 mm. Traps were changed at intervals of approximately three to four months. When recovered, the tops of the traps were sealed and the contents (sediment and water) later processed by gravimetric settling of particulate material from a known volume of water onto a pre-weighed membrane filter. Four replicate 60 ml sub-samples were measured from the trap contents and stored frozen and transported to the Particle Analysis Service Laboratory of CSIRO where samples were processed to determine particle size distributions (PSD) and the total dry weight of sediment. Mean rates of sediment accumulation (mg cm^{-2} d^{-1}) were derived for each trap location for each period of deployment and seasonal averages were calculated for these estimates. Net weight of different sediment types and mean sediment size (mean micron) were measured using up to replicate samples taken from each location. Initially, mean sediment size was grouped into nine size classes ranging from clay to coarse sand, however for our analysis these size classes are grouped into three broad categories (clay, silt and sand).

To assess variation in temperature regimes among communities (3–6 m depth) i*n situ* temperature readings were collected every 2–15 minutes using VEMCO Minilog-II-T data loggers from 2003-2017. In addition, satellite SST data and local currents were modelled to produce tidal cooling indices for communities (see Bird 2005 for details). Tidal mixing is the interaction of currents with the substratum through friction that creates bottom-up mixing, while solar heating acts to stabilise the water column (Bird 2005). Tidal cooling provides an indication of locations that are well mixed and deep enough to generate considerable surface cooling. Maps of these modelled variables were created, from which mean values were derived for each of the seven monitoring locations (1 km^2) for modelled current speed and mixing.

Adjacent to (20–40m depth) all inner-slope communities, current speed, wave height, salinity, fluorescence, turbidity and Photosynthetically Active Radiation (PAR) were quantified using Seabird SBE16 loggers with integrated Wetlabs ECO FLNTU and ECO PAR optical sensors between May 2008 and April 2009. From these data, PAR was extrapolated for each location at 9 m depth. Water column current profiles and wave heights were quantified using Nortek 600 kHz AWAC and Nortek 1MHz Aquapro Acoustic Doppler Current Profilers (ADCP) with wave capability. The current profilers were mounted adjacent to the water quality loggers at four locations and acoustically recorded vertical current velocities through the water column as five-minute averages, every 30 minutes.

All environmental data were explored and summarised as either mean or maximum averages per location per day, in addition to mean maximum current speeds and wave heights. Sediment particle size and weight, turbidity and chlorophyll were averaged at each location d^{-1} + S.E. for summer and winter seasons (**Appendix 2c**). For all environmental parameters, data were summarised in ways that best explained the spatial variation among study locations. From this initial exploration, the contribution of parameters to variation in habitat conditions among study locations was formally investigated using Principal Components Analysis (PCA) of the normalised data in the software PRIMER (Clarke and Warwick 2001). Parameter statistics that explained a low proportion of the variation among locations, and those that were highly correlated ($r > 0.9$) with another parameter that better explained variation, were excluded and the analyses repeated (**Table 2**). Of the many parameters that were initially investigated, nine remained after excluding those which explained a low proportion of variation and those highly correlated ($r > 0.9$) with another (**Appendix 2b**). The final parameters were: percentage cover of sand, cumulative wind speeds, range in water temperature, rate and composition of sedimentation, turbidity and chlorophyll concentration (fluorescence), and maximum current speed and wave height, in summer and/or winter months.

Table 1: Benthic groups used to describe coral communities at locations across Scott Reef and the Rowley Shoals. Most groups were common at most communities during one or more periods, except for groups that were most common at the South Lagoon (South Reef); and groups that characterised the Mermaid Reef community.

Benthic group	**Description**	
Non-coral		
Crustose coralline algae	Crustose coralline algae and fine turf algae, suitable for colonisation by coral recruits.	
Macroalgae + sponge	Large fleshy algae and sponges, which are rare across the reef systems, and which can exclude and outcompete coral recruits.	
Millepora	Hydrozoa within the Family Milleporidae.	
	Scott Reef	**Rowley Shoals**
Soft coral	Mostly *Sinularia* and *Lobophytum* (≈ 40%), *Sarcophyton* (≈10%), found in all communities but most common at the Channel and Inner South West.	Mostly *Lobophytum* and *Sinularia* (> 75%) found in all communities but most common at Mermaid Reef.
Hard coral		
Acropora	Including tabulate, corymbose, digitate growth forms common across Scott Reef, and arborescent and hispidose growth forms most common at the South Lagoon.	Including tabulate, corymbose, digitate and branching growth forms common across the Rowley Shoals.
Diploastrea	N/A (rare at Scott Reef).	Characteristic of Mermaid Reef.
Foliose corals	*Echinopora* (≈55%) and other foliose corals, most common at the South Lagoon community.	*Echinopora* (≈ 40%) and other foliose corals.
Isopora	*I. brueggemanni* (≈ 80%) and *I. palifera* (≈ 20%).	*I. brueggemanni* (≈ 25%) and *I. palifera* (≈ 75%).
Merulinidae	*Goniastrea, Coelastrea, Dipsastrea, Favites* and other Merulinidae species, with mostly a massive growth form. Corals from the Family Diploastreidae and the genus *Leptastrea* (Insertae Sedis) are also included in this group.	*Goniastrea, Coelastrea, Dipsastrea, Favites* and other Merulinidae species, with mostly a massive growth form. Corals from the genus *Leptastrea* (Insertae Sedis) are also included in this group.
Montipora	Mostly *Montipora* (≈75%), and other encrusting corals.	Mostly *Montipora* (> 60%), and other encrusting corals.
Pavona	N/A (rare at Scott Reef)	Including encrusting and submassive growth forms.
Pocilloporidae	*Pocillopora, Seriatopora, Stylophora.*	*Pocillopora, Seriatopora, Stylophora.*
Porites branching	Most common at the South Lagoon.	N/A (rare at Rowley Shoals).
Porites massive	Common across Scott Reef, but dominant at the Channel and Inner South West.	Common across the Rowley Shoals.

Table 2: Parameters used to characterise routine habitat conditions at locations across Scott Reef. Six parameters were quantified at all but one (Outer Seringapatam) location and an additional 9 parameters at the inner-slope locations. All data are for the long-term monitoring locations (9 m), unless stated. Summary statistics were produced for each parameter, and a reduced number used in the final analysis after removing statistics that explained a low proportion of the variation among locations, and those that were highly correlated (r > 0.9) with another parameter that better explained variation.

	Parameter	Initial estimate	Parameter revision	Final estimate
All locations	Temperature (July 06 to Oct 14)	Mean daily temperature (°C)	Excluded	
		Mean range in daily temperature (°C)	Divided among seasons; all but summer excluded	Summer range in daily temperature (°C)
	Sedimentation (May 08 to April 09)	Mean daily weight of sedimentation ($mg\ cm^{-2}\ day^{-1}$)	Divided between summer and winter months	Mean daily weight of sedimentation in summer and in winter ($mg\ cm^{-2}\ day^{-1}$)
		Mean sediment particle size (µm)	Excluded	
		Percentage composition of sediment particle sizes, for nine size classes ranging from clay to course sand (µm)	Divided between summer and winter months and size classes combined	Mean percentage of silt and clay (<63µm), sand (63-500µm) and coarse sand (>500µm), in summer and winter months
	Cover of sand (Oct 94 to Oct 10)	Cover of sand on substrata each year (%)	Averaged over all years	Mean cover of sand (%)

2.3.2 Temporal variation in acute disturbances

Throughout the monitoring period, coral communities at one or more locations at Scott Reef and the Rowley Shoals experienced heat stress and coral bleaching, damaging waves generated by cyclones and storms, and an outbreak of coral disease. Heat stress was quantified by Degree Heating Weeks (DHW), extracted from NOAA Coral Reef Watch's 5km global dataset v3.1 (NOAA 2018). DHW values were extracted for pixels overlying study sites using MATLAB R2017b (http://www.mathworks.com/) and averaged for each reef. The duration of heat stress was defined as the period when DHW exceeded 4 °C-weeks. Damaging waves (both cyclonic and non-cyclonic) were identified for each monitoring site, then averaged to reef level. Hourly cyclone-generated wind speeds were reconstructed along cyclone tracks from 1985 to 2015 (McConochie et al. 2004). To account for the contribution of non-cyclonic winds to sea state, at each time step cyclone-generated winds were blended with synoptic winds (https://climatedataguide.ucar.edu/climate-data/climate-forecast-system-reanalysis-cfsr). Cyclonic winds were weighted by proximity to cyclone centres, and synoptic winds weighted by increasing distance beyond 3 radii of the cyclone eye. Following Puotinen et al. (2016), data and fetch were used to estimate whether the resulting waves were capable of damaging coral colonies, with damaging waves defined as having the top one-third of wave heights ≥ 4 m (significant wave height [H_s] ≥ 4 m). A lack of high-resolution bathymetry and reef/island mapping prevented any adjustment of localised fetch effects using custom-fit numerical wave models. However, for each cyclone from November 2010 – May 2018, wave height and direction were extracted from the nearest WaveWatch III global hindcast dataset at ~ 50 km resolution (http://polar.ncep.noaa.gov/waves/index2.shtml) (Tolman 2009) and maps of the study sites used to assess the exposure of each long-term monitoring location to damaging waves. For cyclones from January 1998 – December 2013, a finer-resolution assessment was possible using data extracted from an Australia-wide hindcast wave dataset produced by CSIRO and BOM at 11 km resolution using the WaveWatch III model.

3. Results

3.1 Scott Reef

3.1.1 Periods of impact and recovery across Scott Reef

Over 23 years, acute disturbances of varying severity impacted Scott Reef (**Figure 2**), but the system's resilience was facilitated by the lack of chronic disturbances, high water quality and abundant fish stocks. The most severe disturbances caused mean reductions in coral cover across the entire reef system and affected all coral groups, with recovery taking several years to over a decade. Moderate disturbances reduced coral cover at one or more communities, usually for a subset of coral groups, and recovery took less than a few years.

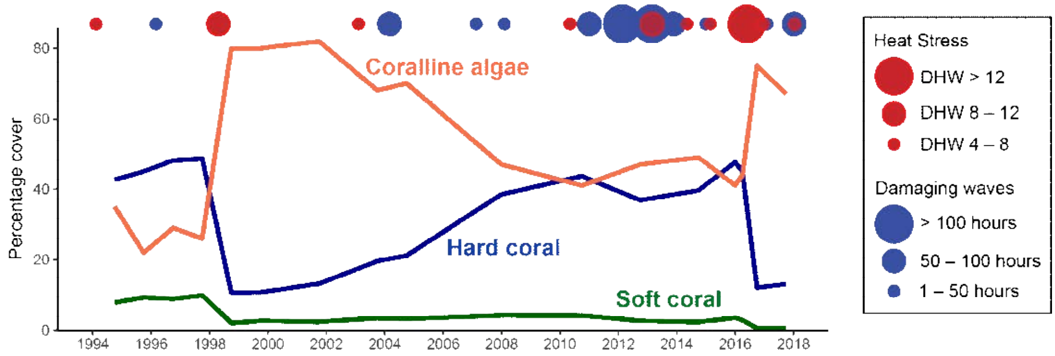

Figure 2: Over 23 years multiple acute disturbances altered community structure across Scott Reef. Disturbances were heat stress (DHW > 4 °C-weeks) and damaging waves from storms and cyclones (significant wave heights ≥ 4 m).

From 1994 to 2017, total coral cover (hard corals, soft corals, *Millepora*) across the reef system was 37%, and ranged from 12% to 61%. Reductions in cover were caused by damaging waves generated by cyclones and tropical lows, heat stress causing coral bleaching and a single outbreak of coral disease. Damaging waves (significant wave heights ≥ 4 m) impacted the reef system 13 times (**Table 3**) but affected only a few exposed communities. Heat stress (DHW > 4 °C-weeks) occurred 9 times, including three periods predicted to cause wide-spread bleaching and mortality (DHW ≥ 8 °C-weeks; **Table 3**). Mass bleaching in 1998 reduced coral cover to the lowest on record (**Figure 2**). Subsequent recovery was slowed by the local effects of cyclones and coral bleaching, but by 2010 the mean cover of hard corals had reached pre-bleaching levels; although cover of soft corals was still approximately half that prior to the 1998 mass bleaching (**Figure 2**). From 2010, heat stress and damaging waves were more frequent, but cover had increased to 51% by January 2016. Heat stress in April 2016 was the most severe on record and mass bleaching caused another large reduction in coral cover, which in 2017 was similar (14%) to that following the 1998 mass bleaching (**Figure 2**). Through the cycles of impact and recovery, benthic communities were dominated (86%) by hard corals, soft corals and coralline algae (**Figure 2**). Following the loss of corals, the available substrata were colonised by coralline algae, whereas the cover of other benthic groups (e.g. sponges, macroalgae) remained low (< 7%).

The changes in community structure across Scott Reef were driven by their exposure to two mass bleaching events and many less-severe disturbances. However, community dynamics were also mediated by the routine environmental conditions at each location and the life histories of the dominant coral taxa. The temporal dynamics grouped into five periods of impact and recovery (**Appendix 3**), which were also indicative of the condition of the reef system:

1) Pre-bleaching (1994–1997): Start of monitoring and before mass bleaching;
2) Mass bleaching (1998–2001): Up to three years after mass bleaching;
3) Post-bleaching (2002–2004): Up to six years after mass bleaching;
4) Recovery and multiple disturbances (2005–2015): Seven to fifteen years after mass bleaching;
5) Mass bleaching (2016–2017): Up to two years after mass bleaching.

3.1.2 Pre-bleaching and local environmental conditions (1994–1997)

In the absence of severe disturbances, the structure of coral communities reflected local environmental variation. Communities were distinguished by water temperatures, current speeds, exposure to winds and waves, and water quality (sedimentation, chlorophyll and turbidity) (**Appendix 2, 4, 5**). These conditions varied with proximity to the sheltered lagoon at South Reef, the deep channel between North and South Reef, and the outer eastern slope at each of the three reefs (**Figure 1, Appendix 4, 5**). Consequently, environmental conditions and community structures were most similar at the outer eastern slope locations (Outer South East, Outer North East, Outer Seringapatam), followed by the Inner South East. Communities at the Inner South West, Channel and South Lagoon locations were most unique. The South Lagoon was the most sheltered and its community distinguished by the highest cover of fragile corals, such as the foliose corals (usually *Echinopora*) and *Acropora* (particularly arborescent and hispidose forms). The Inner South West and Channel had the highest current speeds and wave heights, including those generated by seasonal storms and cyclones; they also had the highest daily temperature ranges, due to internal tides and cool water intrusions. The Inner South West and Channel communities had the highest cover of massive *Porites* and soft corals, and the lowest cover of *Acropora* and other fragile growth forms. These fundamental differences in local conditions and community structure influenced the severity of impacts from disturbances and the rates of recovery over the next two decades.

In 1996, damaging waves were generated by Cyclone Kirsty (37 hours $H_s \geq 4$ m, **Table 3**). However, from October 1994 to 1997 mean coral cover (hard corals, soft corals, *Millepora*) across the reef system increased from 53% (± 2) to 61% (± 3). There were comparable increases (7–11%) in cover at most communities, but for smaller increases at those exposed to the damaging waves (3–5% at Channel and Inner South West). Coral cover was high (45–70%) at all communities, with massive *Porites, Montipora*, soft corals, *Acropora* and *Isopora* the most common taxa (5–15%), followed by Pocilloporidae and Merulinidae (2–10%) (**Figure 3**).

Table 3: Disturbance history at Scott Reef (Oct 1994–Dec 2017). Heat stress is defined as DHW > 4 °C-weeks (yellow rows) for pixels overlying Scott Reef monitoring locations (NOAA Coral Reef Watch 2018); widespread bleaching and mortality is likely when DHW > 8 °C-weeks (orange rows). Double lines between rows indicate timing of coral monitoring surveys. Where DHW remained at its maximum ("peak date") over more than one day, the peak date given is the first day of the maximum value. Cyclone and storm events (blue rows) are defined by hours of damaging seas (H_s > 4 m). A higher number of hours at H_s > 4 m indicates greater potential for wave damage at the coral monitoring sites, assuming vulnerable colonies are present. For pre-2010 cyclones, directions of exposure are unknown and peak dates are approximate (details in Methods).

Event	Year	Peak date/s	Peak DHW	Duration	Bleaching observations; wave direction
Cyclone Kirsty	1996	9-10th Mar		37 hrs	Directions unknown
Heat stress	1998	27th Apr	9.6	90 days	Widespread bleaching and mortality
Heat stress	2003[1]	11th Feb	7.6	83 days	No known surveys, coral cover increased
Cyclone Fay	2004	19th-23rd Mar		54 hrs	E, NE
Cyclone George	2007	4-6th Mar		19 hrs	W, WNW
Cyclone Nicholas	2008	15-16th Feb		23 hrs	W, WNW
Heat stress	2010	27th Apr	7.4	82 days	Bleaching observed at some locations
Cyclone Vince	2011	11-14th Jan		87 hrs	WNW, W
Cyclone Iggy	2012	24-29th Jan		95 hrs	W, WNW
Cyclone Lua	2012	14-18th Mar		168 hrs	W, WNW
Cyclone Narelle	2013	7-11th Jan		62 hrs	W, ENE, NW, WNW
Heat stress	2013[1]	11th Feb	10.4	145 days	Bleaching observed but not quantified
Cyclone Rusty	2013	23rd-28th Feb		135 hrs	W, WNW
Cyclone Christine	2013	28-29th Dec		73 hrs	WNW
Low 05U	2014	19-20th Jan		40 hrs	WSW, W
Heat stress	2014	17th Apr	5.4	68 days	No signs of bleaching in surveys later that year
Low 05U 1	2015	7-9th Jan		48 hrs	W
Heat stress	2015[1]	10th Feb	4.5	47 days	No signs of bleaching in surveys the following year
Heat stress	2016	5th May	16.5	170 days	Widespread bleaching and mortality
Heat stress	2016[1]	21st Dec	5.9	73 days	No known surveys
Cyclone Yvette	2016	22nd-23rd Dec		61 hours	WNW, W
Low 15U	2017	6-8th Feb		39 hours	W, WNW
Heat stress	2017[2]	27th Dec	5.5	13 days	No known surveys
Low 11U	2018	29th-31st Jan		87 hours	W, WNW

[1] Heat stress conditions started in December of the previous year but are listed by the year when heat stress peaked. [2] Heat stress extended past the end of downloaded data (31st December 2017).

3.1.3 Mass bleaching (1998–2001)

In 1998, heat stress (DHW > 4 ° C-weeks) affected the reef system for 90 days, peaking at 9.6° C-weeks in late April (**Table 3**). Mass bleaching was observed in April at all shallow water habitats at all reefs to 20 m depth. Six months later, mean (± SE) hard coral cover decreased from 48% (± 7) to 10% (± 3), a relative decrease of ≈ 80% (**Figure 2**). Among the communities, the relative decreases ranged from 50 to 90% and depended on the abundance of susceptible coral groups. The relative decreases in cover were highest (> 90%) for the branching *Porites*, *Acropora*, *Millepora*, *Isopora*, and Pocilloporidae, ranged from 70 to 90% in the other coral groups, and were lowest (12–75%) in the massive *Porites* (**Figure 3**). The impact of the bleaching also varied among communities according to their environmental conditions. The Inner South West and Channel communities experience less heat stress (**Appendix 2**) and had smaller (< 60%) relative decreases in common taxa than others (> 80%) (**Figure 3, Appendix 6**). For example, the relative decreases in massive *Porites* (5–10%) and Merulinidae (30–55%) at the Inner South West and Channel were lower than at all other communities (massive *Porites* 25–75%, Merulinidae 80–97%).

The mass bleaching had homogenised the reefs, as coral taxa that had previously distinguished communities were also the most susceptible (e.g. *Isopora, Acropora,* Pocilloporidae). Three years later, there were only small increases (< 3%) in cover, due mostly to the regrowth of surviving corals (massive *Porites, Isopora,* soft corals) at communities least affected. The reefs were still characterised by taxa that had been most abundant and most resistant to heat stress, particularly the massive *Porites* and the *Montipora* and encrusting corals (**Figure 3, Appendix 6**).

3.1.4 Post-bleaching (2002–2004)

In 2003, heat stress (DHW > 4 ° C-weeks) affected the reef system for 83 days and peaked at 7.6 °C-weeks in February, followed in 2004 by damaging waves generated by Cyclone Fay (54 hours $H_s \geq 4$ m, **Table 3**). These disturbances had little obvious effect on the coral communities because the most susceptible coral taxa were still rare following the mass bleaching. The reef system had commenced a trajectory back to pre-bleaching structure, and by 2004 mean (± SE) hard coral cover had increased to 19% (± 4) (**Figure 2**). Cover ranged from 9–26% among the communities, depending on the severity of mass bleaching and exposure to Cyclone Fay. However, increases in cover were still driven by the regrowth of corals (*Isopora,* massive *Porites*, soft corals) at the communities least affected by mass bleaching, and by massive *Porites* at most communities.

3.1.5 Recovery and multiple disturbances (2005–2015)

From 2005 to 2010, damaging waves were generated by cyclones George (19 hours $H_s \geq 4$ m) in 2007 and Nicholas (23 hours $H_s \geq 4$ m) in 2008 (**Table 3**). Impacts were largely restricted to susceptible corals (e.g. *Acropora*, Pocilloporidae) at the Channel and Inner South West communities, where cover had increased by 2–12% by 2008, compared to 17–28% at the other locations (**Figure 3**). Heat stress then affected the reef system for 82 days, peaking at 7.4° C-weeks in April 2010. The resulting outbreak of disease and coral bleaching was most severe at South Lagoon, where there was a large decrease (12%) of predominantly *Acropora*. Bleaching in 2010 was also observed at the Inner South East and outer-slope communities, but caused only a small reduction in cover (5%) of Pocilloporidae at Outer Seringapatam.

More than five years after the 1998 mass bleaching, a more rapid return to pre-bleaching structure had commenced across the reef system. By 2010, mean (± SE) hard coral cover was similar (44% ± 3) to that before the mass bleaching and ranged from 35–51% among the communities. Despite the variable susceptibility and reductions in cover among taxa, most had also returned to a similar pre-bleaching cover. The exceptions were a much higher cover of *Acropora* and a much lower cover of *Millepora*, branching *Porites, Isopora* and soft corals (**Figure 3, Figure 4**). *Acropora* had returned to a similar or higher cover at all communities except for South Lagoon, where they were impacted by the recent bleaching. Branching *Porites* and *Millepora* were the most susceptible of all taxa and were previously rare at most communities, so their cover in 2010 had returned to < 20% of that before the mass bleaching (**Figure 4, Figure 5**). *Isopora* were common (10–30%) at most communities before the 1998 mass bleaching but were also among the most susceptible taxa (**Figure 5**) and returned to only 30% of pre-bleaching cover (**Figure 4**). However, local recovery of *Isopora* depended on the post-bleaching cover; where some (0.5–3%) remained, they had returned to between 50% and 130% of their pre-bleaching cover, whereas communities where no (0%) *Isopora* remained had returned to < 20% of their pre-bleaching cover (**Figure 3**). Soft corals were also common (5–20%) at most communities, were moderately susceptible, and had returned to 42% of their pre-bleaching cover (Figure 4). As with *Isopora,* the remaining cover of soft corals influenced their recovery, but in 2010 was lower than before the mass bleaching all at but one community (**Figure 3**).

Between 2010 and 2012, damaging waves were generated by cyclones Vince (87 hours $H_s \geq 4$ m), Iggy (95 hours $H_s \geq 4$ m) and Lua (168 hours $H_s \geq 4$ m), reducing mean cover across the reef system from 44% (± 3) to 36% (± 8) (**Figure 2, Table 3**). Despite causing the first reduction in mean cover since the 1998 mass bleaching, cyclone impacts were restricted to the few communities with a westerly aspect. There were large relative decreases (≈ 65%) in cover at the Channel and Inner South West, where even the most robust corals were impacted (**Figure 3**). For example, the relative decreases in cover at the Channel were 40–55% for the most robust corals (*Montipora* and encrusting corals, Merulinidae, *Porites* and massive corals), 75% for the soft corals, and > 95% for the more fragile corals (*Acropora,* Pocilloporidae). The impacts were greater than those caused by the mass bleaching in 1998 at these communities, and over the next two years small reductions (≈ 1%) in cover had continued for some groups (soft corals, Merulinidae, massive *Porites*). Although the Inner South East was less exposed to the damaging waves, the relative decreases were similar (> 90%) for the most fragile corals, but less for the soft corals (55%) and the most robust corals (5–30%); over the next two years there was a rapid increase (8%) in cover of predominantly *Acropora* and *Isopora*.

Between 2012 and 2016, damaging waves were generated by cyclones Rusty (135 hours $H_s \geq 4$ m) and Christine (73 hours $H_s \geq 4$ m) in 2013, and by tropical lows in 2014 (40 hours $H_s \geq 4$ m) and 2015 (48 hours $H_s \geq 4$ m) (**Table 3**). The Inner South West and Channel were again most exposed to the cyclone impacts. The increases in cover at these communities were largely restricted to the regrowth of massive *Porites* and soft corals following cyclone damage, and in 2015 they had the lowest cover (≈ 28%) of all communities (**Figure 3**). In 2013, the reef system was also affected by heat stress for 145 days, which peaked at 10.4° C-weeks in February (**Table 3**). The associated bleaching was largely restricted to some Pocilloporidae at the outer-slope communities, which had been sheltered from the recent cyclones. By January 2016, mean (± SE) cover across the reef system had increased to 47% (± 7) and was high (50–56%) at all communities but those worst affected by recent cyclones (**Figure 2, Figure 3**). At all communities, *Acropora* (8–15%) and *Isopora* (2–5%) had the largest increases since 2010, but cover of *Millepora*, branching *Porites*, *Isopora* and soft corals was still much lower than before the mass bleaching in 1998.

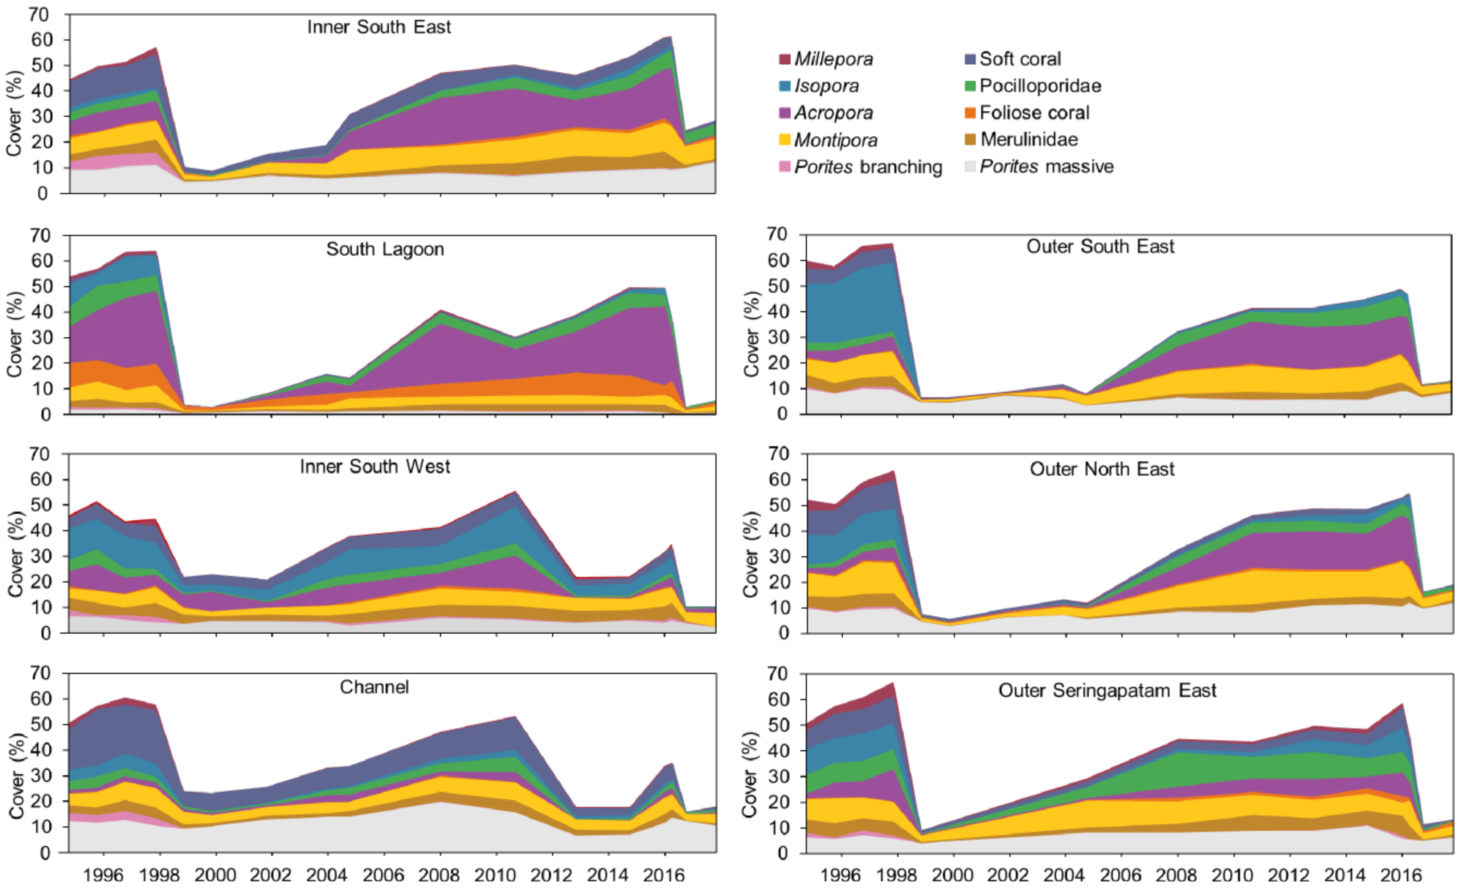

Figure 3: Temporal variation in community structure across the reef system from 1994 to 2017.

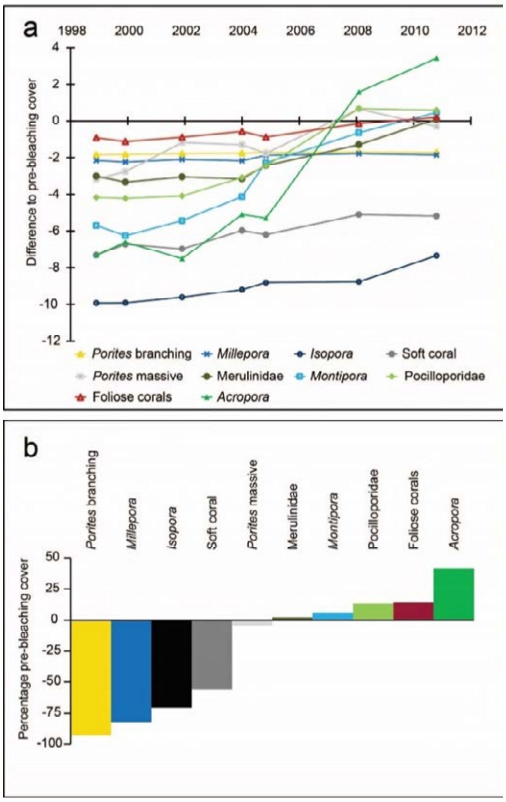

Figure 4: Recovery of coral groups following the 1998 mass bleaching. (a) Difference between mean pre-bleaching (1995 to 1997) cover at each location and in consecutive surveys to October 2010. (b) Mean percentage difference in cover between pre-bleaching years and in 2010.

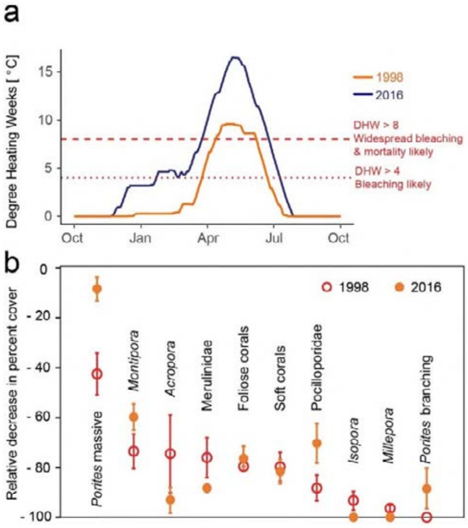

Figure 5: (a) Heat stress at Scott Reef in 1998 and 2016. Duration and maximum Degree Heating Weeks (NOAA Coral Reef Watch 2018); and (b) Susceptibility of coral groups to heat stress and mass bleaching in 1998 and 2016. Mean relative (%) decrease in cover at communities across the reef system, between approximately one year before and after each mass bleaching.

3.1.6 Mass bleaching (2016–2017)

In 2016 and 2017, three periods of heat stress (DHW > 4 °C-weeks) affected the reef system (**Table 3**). The heat stress in early 2016 was the highest on record, persisting for 170 days and peaking at 16.5° C-weeks in May (**Figure 5**). An additional 73 days of heat stress peaked at 5.9° C-weeks in December 2016, and 13 days peaked at 5.5° C-weeks in December 2017 (**Table 3**). Damaging waves were also caused by Cyclone Yvette in 2016 (61 hours $H_s \geq 4$ m) and a tropical low in 2017 (39 hours $H_s \geq 4$ m) (**Table 3**), but the heat stress in early 2016 and the resulting mass bleaching was by far the most severe disturbance.

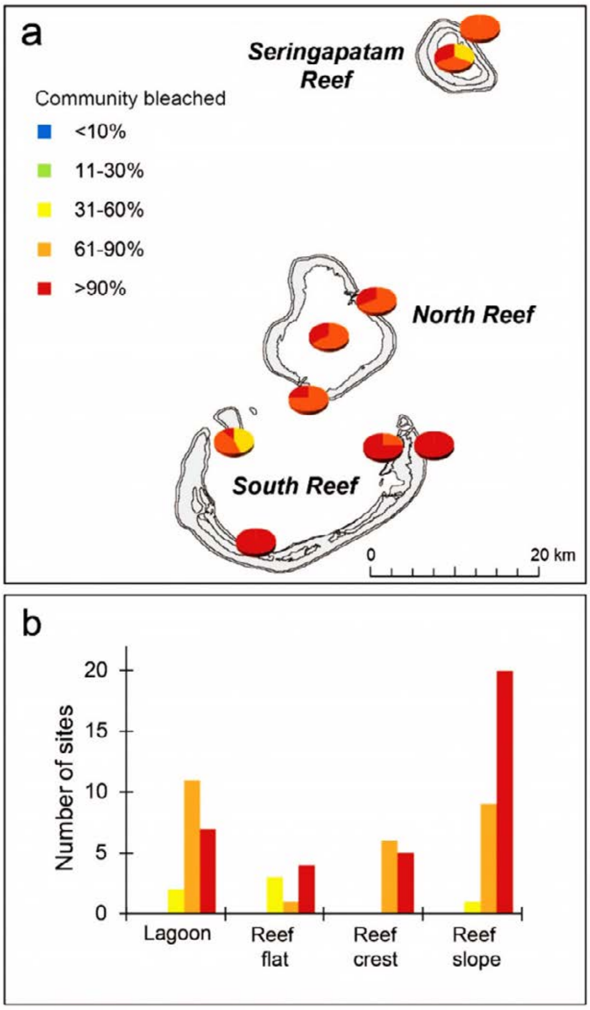

Figure 6: Percentage of bleached corals in April 2016 in communities (a) across the reef system and (b) in each habitat. Habitats are the lagoon (coral bommies and lagoon floor; 0–17m), reef flat (0–3m), reef crest (3–6m) and reef slope (6–9m). Colonies included were fully bleached or recently dead.

Mass bleaching in April 2016 was recorded at all shallow water (< 20 m depth) habitats across Scott Reef, with little variation in bleaching among locations or habitats (lagoon, reef flat, reef crest and reef slope (**Figure 6**). All 69 communities surveyed had > 30% of colonies bleached, and many (30–70%) had > 90% of corals bleached. The sites least affected were on the reef flat or in the deepest (15–20 m depth) parts of the lagoon at North Reef and Seringapatam Reef. Bleaching was observed to 30 m at the deep lagoon at South Reef, but rare at 50 m.

The bleaching estimates and the reduction in coral cover six months later (**Figure 7**) were comparable, with little variation in mortality among reefs, habitats and communities. The mean (± SE) cover of hard corals at the reef crest and reef slope had decreased from 47% (± 8) to 14% (± 5), and the soft coral from 3% (± 2) to 0.6% (± 0.3). The relative reductions in cover were similar (> 70%) at most (9 of 14) communities across the reef system, but lower (40–60%) at those worst affected by recent cyclones and exposed to the lowest heat stress. For example, at the Channel, Inner South West and Inner South East communities, there were smaller relative decreases in cover of massive *Porites* (5%) and *Montipora* (30–60%) than at the other communities (10–33% and 50–80% respectively) (**Figure 3, Appendix 6**). Among the coral groups, the relative decreases in cover were highest (> 90%) for the *Millepora*, branching *Porites, Isopora* and *Acropora*, followed by Merulinidae and soft corals (80–90%), foliose corals (mostly *Echinopora*) and Pocilloporidae (70%–80%), *Montipora* (60%) and massive *Porites* (9%) (**Figure 5; Appendix 6**).

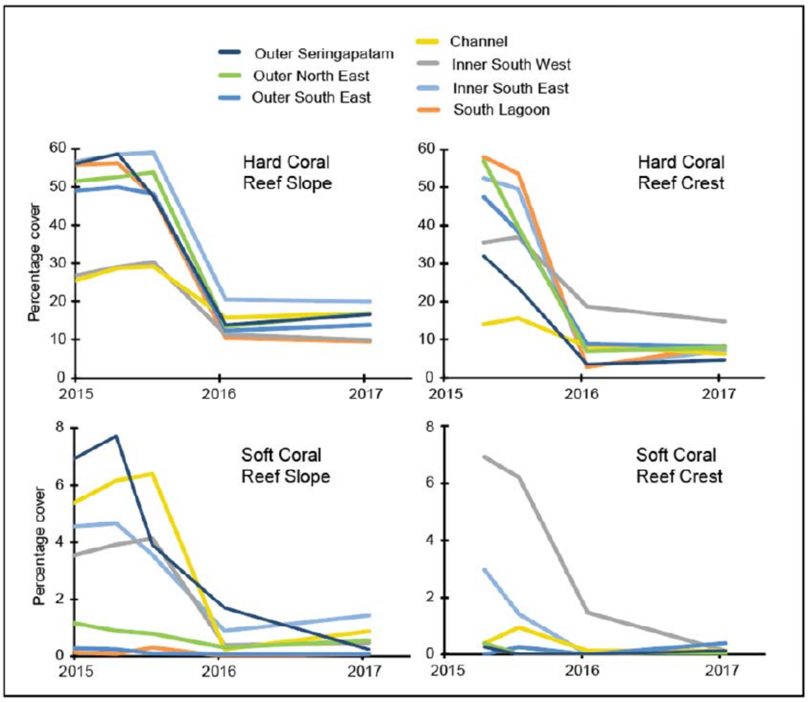

Figure 7: Changes in mean cover of hard and soft corals at reef slope (6 m) and reef crest (3 m) habitats following the 2016 mass bleaching.

3.1.7 1998 versus 2016 mass bleaching

Heat stress in 2016 lasted longer and was more severe (170 days; 16.5° C-weeks) than in 1998 (90 days; 9.6° C-weeks) (**Figure 5, Table 3**). However, the mass bleaching and mortality in 1998 and 2016 were similar in scale and severity, with mean cover across the reef system decreasing from the highest (≈ 50%) to the lowest on record (10–15%). All habitats, locations and coral groups were affected, and the loss of corals was matched by comparable increases in crustose coralline algae (**Figure 2, Figure 3, Figure 5**).

Following the mass bleaching in 1998 and 2016, the coral communities were more similar than at any other time in 23 years, and were distinguished by the loss of *Isopora*, *Acropora*, Pocilloporidae, Merulinidae, and soft corals (**Figure 5, Appendix 6**). However, the relative decreases in mean cover of some taxa were smaller following the 2016 mass bleaching than 1998. Where massive *Porites* were common (> 5% cover), their relative decreases in 2016 were smaller (10–30%) than in 1998 (30–60%), even after excluding communities recently impacted by cyclones. Similarly, in 2016 there were smaller relative decreases in *Montipora* (66%) and Pocilloporidae (62%) than in 1998 (78% and 80% respectively; **Figure 5**). However, the smaller mean reductions in cover for these taxa were mostly at the Inner South East community (**Appendix 6**), where the relative reduction in total hard coral cover was also lower (56%) in 2016 than in 1998 (79%). Among the communities, the Inner South West and Channel consistently had the lowest relative reductions (45–60%) in hard corals following both mass bleaching events, because they experienced more variable temperatures (**Appendix 2**) and had fewer susceptible taxa. For other communities, relative reductions were similar following both mass bleaching events, despite some having a much lower cover of susceptible taxa in 2016 (e.g. *Isopora*, *Millepora*).

3.1.8 Disturbance regimes, community structure and degradation

Over 23 years, Scott Reef transitioned through four general periods of impact and recovery that were indicative of the health of the reef system: healthy (pre-bleaching years, 1994 to 1997), mass bleaching (up to four years after mass bleaching in 1998 and 2016); post-bleaching (five and six years after mass bleaching) and recovery (10 to 15 years after mass bleaching). The most obvious difference between communities among the four states was the reduction in cover of hard and soft corals with increasing degradation, and the corresponding increases in crustose coralline algae (**Figure 8**).

Among the taxa, the massive *Porites*, *Montipora* and Merulinidae consistently characterised communities in all four of the states, because they were common and underwent the smallest changes in cover. However, their relative contribution to the community changed as the system transitioned from the degraded to the healthy states, indicative of the changes in communities when the return times for severe disturbances are less than a decade (**Figure 8**). As the condition of communities improved, the cover of all coral groups increased, but the most significant increases were in the *Isopora*, Pocilloporidae and particularly *Acropora*. Nonetheless, there remained some important differences between the recovery and pre-bleaching states, because the taxa most susceptible and least resilient to the mass bleaching required well over a decade to recover. This included *Millepora* and branching *Porites* that were most susceptible and were previously rare at most communities, and *Isopora* and soft corals that failed to recover at communities where they were worst affected (**Figure 3, Figure 8**).

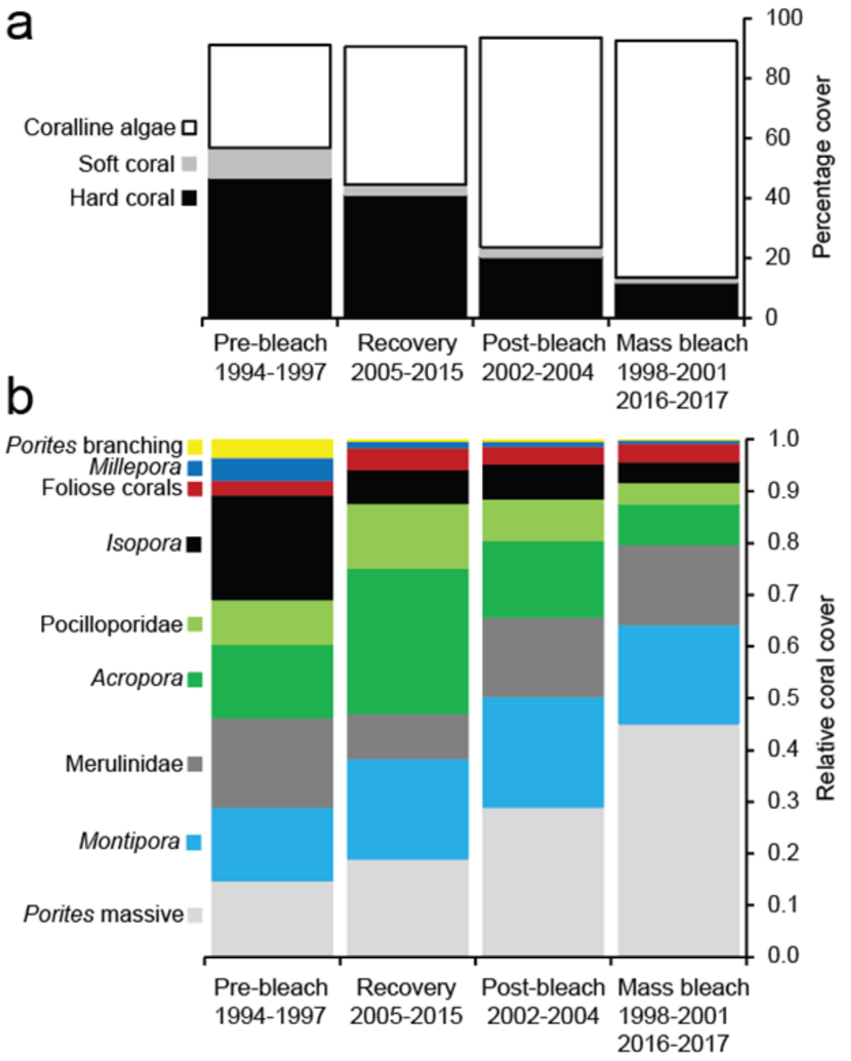

Figure 8: Community structure at Scott Reef in four states of impact and recovery, indicative of the condition of the reef system. States are: Pre-bleaching (1994-1997), Mass bleaching (1998–2001, 2016–2017), Post-bleaching (2002–2004), and recovery from mass bleaching (with local disturbances, 2005–2015); (a) percentage cover of hard corals, soft corals and coralline algae; and (b) relative cover of different coral groups, in each community stage.

3.2 Rowley Shoals

3.2.1 Periods of impact and recovery across the Rowley Shoals

Over 22 years, acute disturbances of moderate severity impacted the Rowley Shoals (**Figure 9**). Although frequent, disturbances usually reduced coral cover in only a few communities and coral taxa, and a rapid recovery was aided by the lack of chronic disturbances, high water quality and abundant fish stocks.

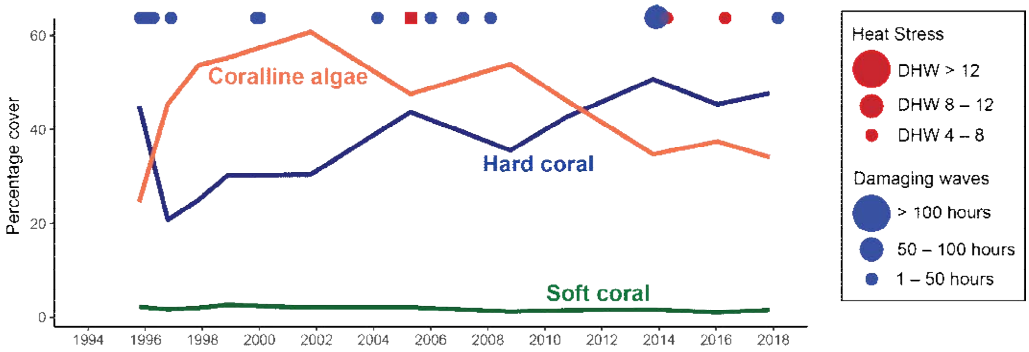

Figure 9: Over 22 years, multiple acute disturbances altered community structure across the Rowley Shoals. Disturbances were damaging waves from storms and cyclones (significant wave heights ≥ 4 m) and heat stress (DHW > 4 °C-weeks). Red square indicates observed moderate bleaching where heat stress did not exceed 4 °C-weeks.

From 1995 to 2017, mean coral cover (hard corals, soft corals, *Millepora*) across the Rowley Shoals was 45% and ranged between 28% and 58%. At least 13 cyclones produce damaging waves (**Table 4**), and eight coincided with mean reductions (up to 22%) in coral cover across the reef system (**Figure 9**). Multiple cyclones caused the largest reduction in mean coral cover, from 50% in 1995 to 28% in 1996. Between 2005 and 2008, another mean reduction in cover (from 52% to 41%) followed three cyclones and a moderate bleaching event (**Table 4**). Heat stress (DHW > 4° C-weeks) occurred three times since 1995, but not in 2005 when moderate bleaching was observed. The highest heat stress on record (5.8 °C-weeks) occurred in 2016, but caused only moderate bleaching at a few sites (**Table 4**). Severe heat stress (DHW > 8° C-weeks) and mass bleaching has not occurred at the Rowley Shoals (**Table 4**). Through cycles of impact and recovery, benthic communities were dominated (> 70%) by hard corals, soft corals and coralline algae (**Figure 9**). Following the loss of corals, available substrata were colonised by coralline algae, while the cover of other benthic groups (e.g. sponges, macroalgae) remained low. Since 1997, mean coral cover has increased through rapid cycles of impact and recovery, and has been consistently high (> 40%) since 2010 (**Figure 9**).

Changes in community structure across the reef system were driven by their local exposure to cyclones and moderate heat stress and mediated by the life histories of their dominant taxa. The temporal dynamics grouped into three periods of impact and recovery (**Appendix 7**), all of which were indicative of a healthy reef system:

1) Cyclone disturbance and decreased coral cover (1996–1997)
2) Recovery, cyclones and coral bleaching (1995, 2001, 2005)
3) Cyclones, recovery and coral bleaching (2008–2017)

Table 4: Disturbance history at the Rowley Shoals (Oct 1995–Dec 2017). Cyclone and storm events causing damaging seas (hours Hs > 4 m) are shown in blue cells. Heat stress is defined as DHW > 4 °C-weeks (yellow cells) for pixels overlying Rowley Shoals monitoring locations (NOAA Coral Reef Watch 2018). Double lines between rows indicate timing of coral monitoring surveys. Where DHW remained at its maximum ("peak date") over more than one day, the peak date given is the first day of the maximum value. A higher number of hours at $H_s > 4$ m indicates greater potential for wave damage at the coral monitoring sites, assuming vulnerable colonies are present. For pre-2010 cyclones, directions of exposure are unknown and peak dates are approximate (details in Methods).

Event	Year	Peak date/s	Peak DHW	Duration (days; hours)	Disturbance observations; wave direction
Cyclone Frank	1995	Dec		3–6 hrs	Directions unknown
Cyclone Gertie	1995	Dec		11 hrs	Directions unknown
Cyclone Jacob	1996	Feb		7 hrs	Directions unknown
Cyclone Olivia[1]	1996	Apr		9 hrs	Directions unknown
Cyclone Phil[1]	1996	Dec		10 hrs	Directions unknown
Cyclone Isla	1999	Dec		21 hrs	Directions unknown
Cyclone John	1999	Dec		30 hrs	Directions unknown
Cyclone Fay	2004	Mar		40 hrs	Directions unknown
Heat stress[2]	2005	27th Apr	2.1	–	Moderate bleaching observed
Cyclone Daryl	2006	Jan		11 hrs	Directions unknown
Cyclone George	2007	Mar		26 hrs	Directions unknown
Cyclone Nicholas	2008	Feb		47 hrs	E
Cyclone Christine	2013	Dec		62 hrs	WNW, E to SE, W
Heat stress	2014	12th Apr	5.6	71 days	No signs of recent bleaching in surveys later that year
Heat stress	2016	28th Apr	5.8	71 days	Minor bleaching
Cyclone Marcus	2018	Mar		20 hrs	NE to ENE to NNE

[1] Wave zones for cyclones Phil and Olivia did not intersect the long-term monitoring sites, but may have caused impacts given the positional uncertainty of these cyclone tracks. [2] Heat stress in 2005 did not exceed 4° C-weeks but moderate bleaching was observed.

3.2.2 Cyclone disturbances and decreased coral cover (1995–1997)

Damaging waves were generated by cyclones Frank (3–6 hours $H_s \geq 4$ m) and Gertie (11 hours $H_s \geq 4$ m) in 1995, and Jacob (7 hours $H_s \geq 4$ m) Olivia (9 hours $H_s \geq 4$ m) in 1996 (**Table 4**). The mean (± SE) cover of hard corals at Rowley Shoals decreased from 45% (± 8) in 1995 to 21% (± 4) in October 1996 (**Table 4**). However, decreases were limited to Clerke (13%) and particularly Imperieuse Reef (46%), mainly due to the loss of *Acropora* (**Figure 10**). In contrast, at Mermaid Reef hard corals had increased (7%), mainly due to *Millepora* (**Figure 10**).

Cyclone Phil generated damaging waves (10 hours $H_s \geq 4$ m) in December 1996. By 1997, cover had changed little at Clerke and Imperieuse reefs and had increased (13%) at Mermaid Reef, due mainly to encrusting corals (10%). Following the recent cyclones, *Acropora* were rare (< 2%) at all three reefs in 1997 and Merulinidae, *Millepora* and encrusting corals were most common (3–16%) (**Figure 10**).

3.2.3 Recovery, cyclones and coral bleaching (1998–2005)

Damaging waves were generated by cyclones Isla (21 hours $H_s \geq 4$ m) and John (30 hours $H_s \geq 4$ m) in December 1999 (**Table 4**). Between 1997 and 2001, the cover of hard corals had decreased (13%) at Mermaid Reef, due to the loss of Merulinidae (2%), *Diploastrea* (3%) and particularly encrusting corals (8%). In contrast, cover increased at Clerke (13%) and Imperieuse reefs (16%), due to large increases of *Acropora* (9–10%) and smaller (< 4%) increases of Pocilloporidae and massive *Porites* (≈ 4%) (**Figure 10**).

Damaging waves were generated by Cyclone Fay (40 hours $H_s \geq 4$ m) in 2004 (**Table 4**). Between 2001 and 2005, hard coral cover changed little at Mermaid Reef, but increased at Clerke (17%) and Imperieuse (24%) reefs, due to large increases (13–22%) in *Acropora* and smaller increases (< 5%) in *Isopora* and other coral groups (**Figure 10**). Coral communities in 2005 were similar at Clerke and Imperieuse reefs, with a relatively high cover of and *Acropora* (24–32%) and *Isopora* (4–5%; **Figure 10**), whereas *Acropora* were rare (< 3%) at Mermaid Reef and cover of *Diploastrea*, *Millepora*, and soft corals was higher (6–8%).

Coral bleaching was observed at all three reefs during the survey in March 2005, despite DHW not exceeding 4° C-weeks (maximum 2.1° C-weeks, **Table 4**). Moderate bleaching has been recorded on other reefs at levels of 2° C-weeks, showing that other factors influencing bleaching, such as fine-scale variability in temperatures, may not be captured by satellite sea-surface temperatures (SST) and the derived DHW metric. 10–50% of *Acropora*, Pocilloporidae, Merulinidae and *Diploastrea* colonies had bleached, but the incidence of bleaching varied among reefs. Most of the bleached corals were alive when surveys were conducted and there was little evidence of recent mortality.

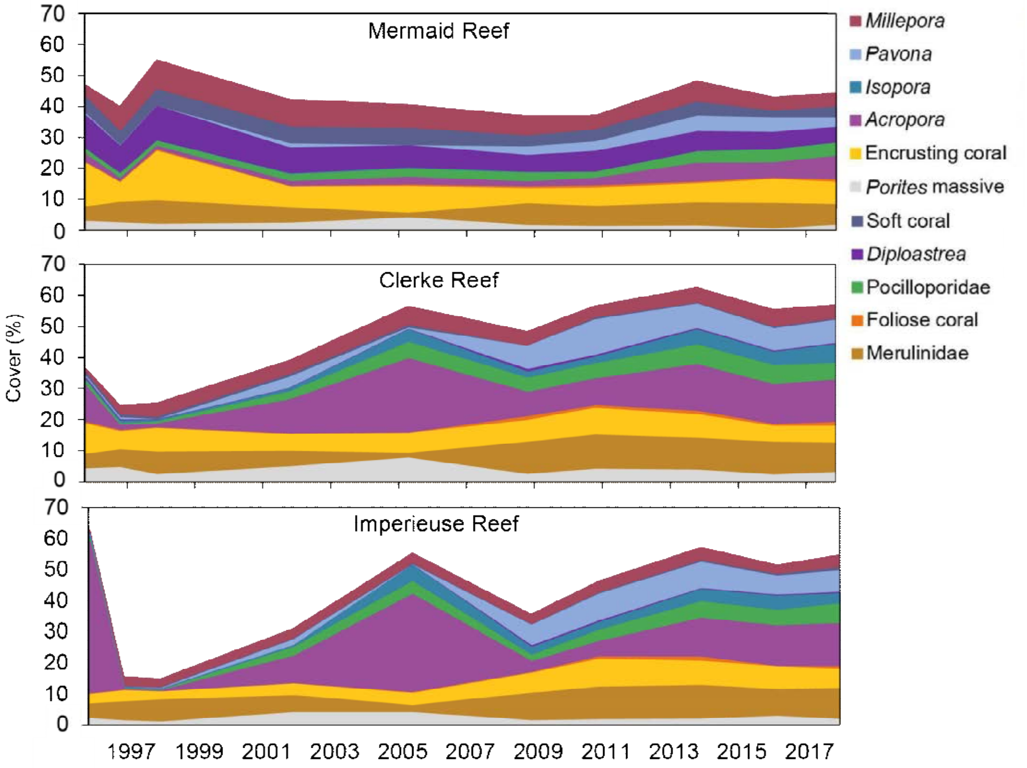

Figure 10: Temporal variation in community structure at reef slope locations at the Rowley Shoals from 1995 to 2017.

3.2.4 Cyclones, recovery and coral bleaching (2006–2017)

Damaging waves were generated by cyclones Daryl (11 hours $H_s \geq 4$ m) in 2006, George (26 hours $H_s \geq 4$ m) in 2007, and Nicholas (47 hours $H_s \geq 4$ m) in 2008 (**Table 4**). The combined effects of these cyclones and coral bleaching in 2005 (**Table 4**) caused a mean reduction in cover across the Rowley Shoals from 2005–2008. Decreases in cover of hard corals were larger at Imperieuse (20%) than at Clerke (7%) or Mermaid (3%) reefs (**Figure 10**), due to the higher abundance of susceptible corals. In particular, there were large (16–28%) decreases in *Acropora* at Imperieuse and Clerke, and small (< 5%) changes in other coral taxa at all three reefs (**Figure 10**).

Between 2008 and 2013, no cyclones affected the Rowley Shoals and hard corals increased at Mermaid (11%), Clerke (16%) and Imperieuse (22%) (**Figure 10**). *Acropora* had the largest increases in cover at all reefs (4–9%), and there were smaller increases (< 4%) in *Isopora*, Pocilloporidae and encrusting corals. (**Figure 10**). By 2013, most coral taxa had recovered from previous cyclones and coral bleaching, but for *Acropora* at Imperieuse Reef (**Appendix 7**).

Damaging waves were generated by Cyclone Christine (62 hours $H_s \geq 4$ m) in December 2013, and heat stress (DHW > 4 ° C-weeks) affected the reef system for 71 days in 2014, peaking at 5.6° C-weeks in April (**Table 4**). Between 2013 and January 2016, mean hard coral cover had decreased at Clerke (11%) and Imperieuse (5%), with the largest decreases in *Acropora* and *Montipora*. There was little change in hard coral cover at Mermaid Reef, but there were small decreases in *Millepora* and soft corals and increases in other taxa.

In 2016, heat stress affected the Rowley Shoals for 71 days, peaking at 5.8° C-weeks in late April (**Table 4**). Little (≤ 10%) or no bleaching was recorded at most reef slope and lagoon sites. However, 30% of the community had bleached at some sites in the Mermaid lagoon (**Figure 11**), particularly *Acropora*, *Montipora* and Fungiids. Despite the bleaching, mean (± SE) hard coral cover across habitats and reefs increased from 45% (± 4) in January 2016 to 48% (± 6) in 2017 (**Figure 9**). The increases in cover were largest (3–4%) at the reef slope at Clerke and Imperieuse reefs, due mainly to increases in *Acropora* (**Figure 10**). The largest decreases (4%) in cover occurred at the few sites in the Mermaid lagoon that experienced the worst bleaching (**Figure 12**), mainly due to the loss of *Acropora*. However, mean cover at the other lagoon sites, and across Mermaid Reef, had changed little by 2017 (**Figure 12**).

In 2017, the differences in reef slope communities across the Rowley Shoals were consistent with those throughout the monitoring period (**Figure 10; Appendix 7**). Reef slope communities at Imperieuse and Clerke were most similar, characterised by a higher cover of Pocilloporidae, *Isopora*, massive *Porites* and particularly *Acropora*. Hard coral cover was generally higher and more variable at Imperieuse and Clerke reefs, due mainly to changes in *Acropora*. In contrast, Mermaid Reef was distinguished by a higher cover of *Diploastrea*, *Millepora* and soft corals. Hard coral cover was usually lower and less variable at Mermaid Reef, due to the low cover of *Acropora*. Merulinidae, *Montipora* and other encrusting corals were common at all three reefs and remained relatively stable through time (**Figure 10**).

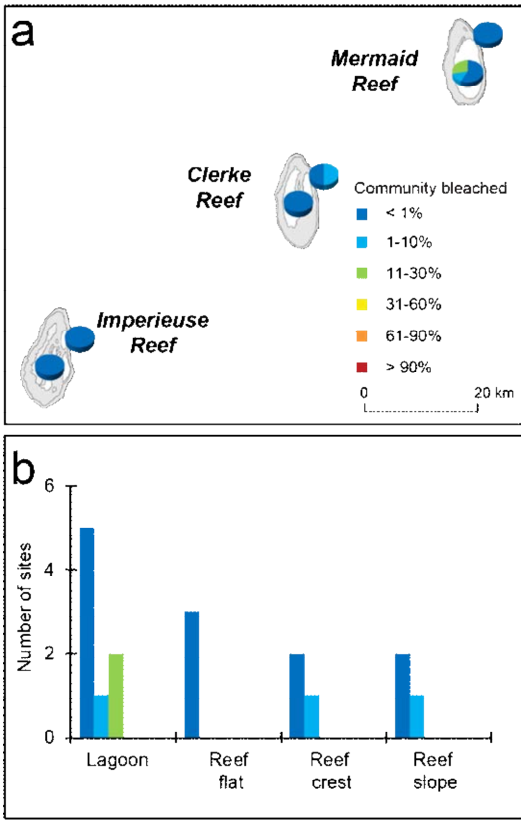

Figure 11: (a) Percentage of bleached corals in communities across the reef system in April 2016, and (b) number of sites in each habitat, using the same categories. Habitats are the lagoon (including coral bommies and lagoon floor), reef flat (0–3m), reef crest (3–6m) and reef slope (6–9m). Colonies included were fully bleached or recently dead.

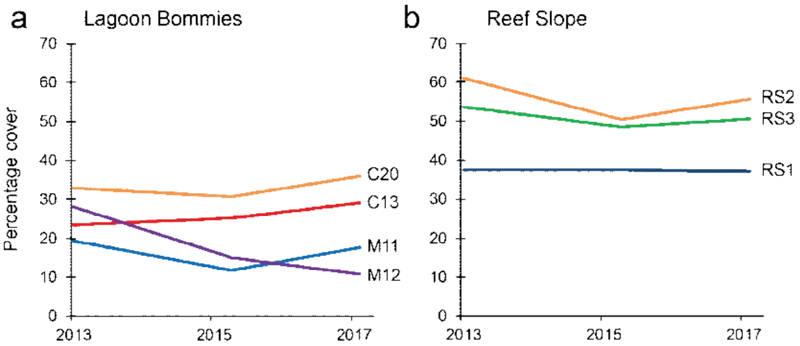

Figure 12: Hard coral cover in (a) lagoon bommie and (b) reef slope habitats at the Rowley Shoals in 2013–2017. Lagoon bommie sites were at Mermaid Reef (M11, M12) and Clerke Reef (C13, C20). Reef slope sites were at Mermaid Reef (RS1), Clerke Reef (RS2) and Imperieuse Reef (RS3).

4. Discussion

4.1 Twenty-three years of disturbances

Over 23 years, coral communities across Scott Reef underwent significant change, driven by two mass bleaching events and frequent moderate disturbances. During the same period, communities at the Rowley Shoals also changed in response to frequent moderate disturbances but did not suffer the severe and widespread impacts caused by mass bleaching. Damaging waves generated by cyclones caused mean decreases in coral cover three times at the Rowley Shoals and once at Scott Reef, but usually affected exposed communities and coral taxa with fragile growth forms. At Scott Reef, there were nine periods of heat stress, two mass bleaching events and at least two moderate bleaching events; at the Rowley Shoals, there were only two periods of heat stress and moderate bleaching events. Coral communities at Scott Reef experienced large variation in impact and recovery, with coral cover in 2017 near the lowest on record. Coral cover varied less at the Rowley Shoals and has remained high since 2014. The very different dynamics of these reef systems highlight the impacts of mass bleaching on coral reefs, and how these are mediated by local environmental conditions and coral life history traits.

4.2 Disturbances mediated by local environmental variation

Local environmental conditions play a fundamental role in structuring coral communities, even within a common habitat (Done 1982; Hughes et al. 2012; Schmidt et al. 2012; Zinke et al. 2018). Across the reef slope habitat at Scott Reef, variation in temperatures, wave energy, current speeds and water quality influenced the structure of coral communities, particularly in the absence of severe disturbances. The location on the reef and environmental conditions also mediated exposure to disturbances. For example, the Inner South West and Channel were most exposed to seasonal storms and cyclones, but are also flushed by internal waves bringing cool water from the deep (Bird 2005; Green et al. 2018; Rayson et al. 2018; Green et al. 2019). Cool water intrusions, higher current speeds and tidal mixing at the Channel and Inner South West communities reduced heat stress and bleaching in both 1998 and 2016 at Scott Reef. These localized reef hydrodynamics, singularly or in combination, have also been shown to reduce heat stress and bleaching at other reefs (Wall et al. 2015; Safaie et al. 2018; Page et al. 2019). Local reductions in heat stress and bleaching also occurred at the southern part of the Seringapatam lagoon in 2016 (**Figure 6**), following night-time cooling of water over the reef flat (Green et al. 2018). Conversely, more severe bleaching at other parts of the reef was due to the flow of warm water out of lagoons, low current speeds and limited tidal mixing. Fine-scale variation in hydrodynamics, water quality and light penetration all can influence local heat stress and the severity of coral bleaching (Nakamura and van Woesik 2001; McClanahan et al. 2007; Skirving et al. 2017; Page et al. 2019).

Local conditions also influenced the recovery of communities following severe disturbances. Reef structure and hydrodynamics determine patterns of larval connectivity among communities and rates of recruitment (Hughes et al. 1999; Becerro et al. 2006; Sato et al. 2018; Torda et al. 2018). All three atolls at the Rowley Shoals have similar shapes, which limits the dispersal of spawning and particularly brooding corals outside of each lagoon, but aids connectivity among the outer slope habitats at each reef (Thomas et al. 2019). At Scott Reef, local hydrodynamics are strongly influenced by the open lagoon at South Reef and the flow of water through the deep channel adjacent to North Reef (Green et al. 2018; Rayson et al. 2018; Green et al. 2019). The Outer South East and Channel at Scott Reef had consistently low recruitment because larvae were carried away by currents, while the Inner South East and Outer North East had the highest recruitment because larvae were concentrated by local eddies (Gilmour et al. 2013a; Rayson et al. 2018). Following larval recruitment, growth and survival of colonies were also influenced by local environmental conditions, and communities returned to their previous structure. There was no evidence of previously rare taxa becoming dominant at Scott Reef after the mass bleaching, or of major shifts in community structure towards less susceptible species. Long-term shifts in community structure on other reefs usually reflect the loss of susceptible taxa, rather than the proliferation of previously rare corals (Done et al. 2007; Hughes et al. 2018a; Torda et al. 2018; Edmunds 2019). More than a decade after the mass bleaching at Scott Reef, communities were distinguished by the loss of coral taxa whose life history traits (susceptability, growth reproduction) had made them most vulnerable to the heat stress.

4.3 Susceptibility, recovery and coral life histories

Both disturbances and routine environmental conditions structured coral communities through the life histories of their dominant taxa. At Scott Reef and Rowley Shoals, there were common patterns of susceptibility to cyclones and heat stress, with the *Acropora*, *Isopora,* Pocilloporidae generally most susceptible, and *Montipora*, Merulinidae, and massive *Porites* least susceptible. This variation in susceptibility is consistent with most other studies of coral reefs (Marshall and Baird 2000; Loya et al. 2001; McClanahan 2004; Hoey et al. 2016). However, the vulnerability of taxa depends on both their initial susceptibility (resistance) and capacity to recover (resilience) over many years (Van Woesik et al. 2011; Carturan et al. 2018). For example, when considering both the initial decreases in cover at Scott Reef following the 1998 mass bleaching and increases in cover over the following 12 years, taxa with very different life histories displayed similar levels of long-term vulnerability. Susceptible taxa recovered more rapidly while those least affected showed slower increases in cover. *Acropora* and Pocilloporidae were more susceptible to disturbances but had higher recruitment and growth rates (Harrison and Wallace 1990; Graham et al. 2011; Van Woesik et al. 2011). Their initial recovery was slow because most colonies were killed, but increased rapidly over several generations. Merulinidae, soft corals and massive *Porites* had lower susceptibility to disturbances and lower rates of sexual recruitment and growth (Harrison and Wallace 1990; Babcock 1991; Fabricius 1995; Fong and Glynn 2000; Van Woesik et al. 2011). Regrowth of injured soft corals and massive corals resulted in small initial increases in cover following cyclones and mass bleaching, but this slowed when recovery relied on recruitment.

The capacity for larval dispersal also influenced the recovery of different coral taxa following the 1998 mass bleaching. For the most susceptible taxa at the worst affected communities, recovery depended on the supply of recruits from other locations (Underwood 2009). Coral taxa with few local survivors and a low capacity for dispersal had not recovered a decade after the mass bleaching. This included the branching *Porites* and the hydrocoral *Millepora* that were already rare before the mass bleaching, and the soft corals and *Isopora* that were previously common. The slow growth of the dominant soft corals (*Sarcophyton, Lobophytum*, *Sinularia*) and their reliance on asexual replication (Fabricius 1995; Michalek-Wagner and Willis 2001; Bastidas et al. 2004) meant they remained at < 30% of pre-bleaching cover 10 years later. The recovery of *Isopora* also depended on local survivors, since their brooded larvae typically dispersed less than a few kilometres (Harrison and Wallace 1990; Underwood et al. 2009; Foster and Gilmour 2018; Thomas et al. 2019). Recovery had occurred within a decade at the two communities where the cover of *Isopora* was highest post-bleaching, but there had been little or no recovery at communities where few colonies had survived. Despite their susceptibility, broadcast spawning *Acropora* and *Pocillopora* produced many larvae that dispersed across the reef system, aiding the recovery of populations worst affected (Underwood 2009; Harrison 2011; Gilmour et al. 2013b; Thomas et al. 2019). As a result, *Acropora* were the only taxa whose cover was consistently higher at all communities more than a decade after the mass bleaching than before, with a similar transition observed on other reefs with a supply of larvae and several years without severe disturbance (Thompson and Dolman 2010; Johns et al. 2014; Torda et al. 2018). The ecological consequences of life history variation in corals is increasingly recognised (Darling et al. 2013; Done et al. 2015; Madin et al. 2016; Torda et al. 2018) and provides valuable insights into the viability of reefs through climate change. To successfully manage reefs through changing regimes of disturbance, life history variation must be considered in the context of functional importance to reefs (Darling et al. 2017) natural capacity for adaptation, and suitability for restoration efforts (Anthony 2016; McLeod et al. 2019).

4.4 Resilience of Scott Reef and the Rowley Shoals to past and future disturbance regimes

The 1998 global coral bleaching highlighted the threat of climate change to coral reefs (Hoegh-Guldberg 1999; Wilkinson 2000). Many reefs devastated in 1998 have not recovered, due to additional bleaching and local pressures (Baker et al. 2008; Sheppard et al. 2008; Graham et al. 2011; Bruno et al. 2018; MacNeil et al. 2019). Isolated reefs, including Scott Reef and the Rowley Shoals, are less exposed to local pressures (e.g. degraded water quality, pollution, depleted fish stocks), and have recovered faster, but the lack of larval connectivity with other reef systems also increases susceptibility to reef-wide reductions in population stocks (Graham et al. 2006; Sandin et al. 2008; Holbrook et al. 2018). At Scott Reef, there was a comparable decrease in coral cover and recruitment following the mass bleaching and this stock-recruitment relationship remained through the recovery period (Gilmour et al. 2013b). Recovery across the reef system relied on the surviving corals and their offspring, and not the supply of recruits from other reef systems (Underwood et al. 2009; Underwood et al. 2018). Nonetheless, high post-recruitment growth and survival was facilitated by high water quality, healthy fish stocks and a decade (1999-2009) with few disturbances (Gilmour et al. 2013b).

The heat stress in 2016 at Scott Reef was the worst on record and the mortality that followed was comparable to that in 1998, with similar variation among communities and coral groups. A recovery trajectory of 10–15 years would therefore be expected, if the future disturbance regime was also similar. However, the frequency and severity of disturbances at Scott Reef have increased since 2010, and a similar pattern is evident at many other reefs in Western Australia and around the world (Hughes et al. 2018b; Gilmour et al. 2019). With further climate change (Hoegh-Guldberg et al. 2018; Steffen et al. 2018), cyclones are expected to produce more damaging waves (Chand et al. 2017; Cheal et al. 2017; Simpkins 2018) and rising ocean temperatures (Raftery et al. 2017) are expected to increase outbreaks of coral diseases (Harvell et al. 2002; Maynard et al. 2015) and the frequency and severity of coral bleaching (Eakin et al. 2018).

Through the previous cycles of impact and recovery, the Scott Reef system transitioned through four general states indicative of the level of degradation and return times for severe disturbances. The healthier states had a much higher coral cover (> 40%) than degraded states (< 20%), but corals were replaced by crustose coralline that facilitates coral recruitment (Harrington et al. 2004). The space available for recolonization reflects the potential for the reef to recover, rather than permanently transitioning to a state in which algae or other benthic invertebrates dominate (Hoegh-Guldberg et al.

2007). Both degraded states also had a much lower cover of *Acropora, Isopora* and Pocilloporidae, which contribute most to the structure of the reef and micro-habitats used by fish and other organisms (Emslie et al. 2008; Wilson et al. 2009; Graham and Nash 2013; Darling et al. 2017; Richardson et al. 2017). These degraded states are indicative of the condition of the reef when recovery periods from severe mass bleaching are < 10 years. In contrast, at the Rowley Shoals communities maintained a healthy state through cycles of impact and rapid recovery from cyclones. Mass bleaching has not affected the reef system, but heat stress in 2016 was the highest on record and the severity of both coral bleaching and cyclones impacts are also likely to increase further at the Rowley Shoals.

The future condition of the Rowley Shoals and Scott Reef fundamentally depend on local water quality, fish stocks and regimes of disturbances, but also on local refuges from cyclones and heat stress, and the adaptive capacity of their corals. Contrasting susceptibilities and an increased understanding of the coral holobiont highlight the potential for coral adaptation to heat stress (Coles and Brown 2003; Baker et al. 2004; Maynard et al. 2008; Palumbi et al. 2014; Coles et al. 2018; DeCarlo et al. 2019). At all reefs, inferring coral adaptation to heat stress at the reef-scale is confounded by fine-scale variability, community structure, disturbance history and survey methods (percentage cover). Nonetheless, observations at the Rowley Shoals and Scott Reef suggest some adaptation to heat stress. Higher levels of heat stress at the Rowley Shoals in 2014 and 2016 caused similar or less bleaching to that in 2005. At Scott Reef, a similar level of heat stress in 2013 caused far less bleaching and mortality than in 1998, while bleaching was similar in 1998 and 2016 despite more severe heat stress in 2016. Among the coral taxa, the responses to heat stress were not consistent. For example, at Scott Reef the *Acropora* were among the worst affected by bleaching in 1998, 2010 and 2016, but not 2013; massive *Porites*, *Montipora* and Pocilloporidae had smaller relative decreases in cover in 2016 than in 1998, despite a higher level of heat stress. Other reefs also have consistent and contrasting patterns of bleaching susceptibility within and among groups (Pratchett et al. 2013; Palumbi et al. 2014; Hoey et al. 2016; McClanahan 2017; Coles et al. 2018).

Existing data for Scott Reef, the Great Barrier Reef (Hughes et al. 2017), and other reefs around the world, confirm that the current rate of adaptation by corals will not significantly reduce the likelihood of mass bleaching events in coming decades. Instead, reductions in the severity of mass bleaching at reef scales usually reflect a shift to a lower total coral cover and a higher proportion of less susceptible taxa (sliding baselines), rather than rapid and widespread adaptation (Osborne et al. 2017; Hughes et al. 2018a; Edmunds 2019). Management of Scott Reef and the Rowley Shoals must now focus on maintaining high water quality and healthy fish stocks, to aid recovery between acute disturbances (Diaz-Pulido et al. 2010; Jones et al. 2016; Johns et al. 2018; Richmond et al. 2018), and apply our emerging understanding of the reefs' natural capacity to adapt to future conditions (McLeod et al. 2019).

6. Appendices

Appendix I

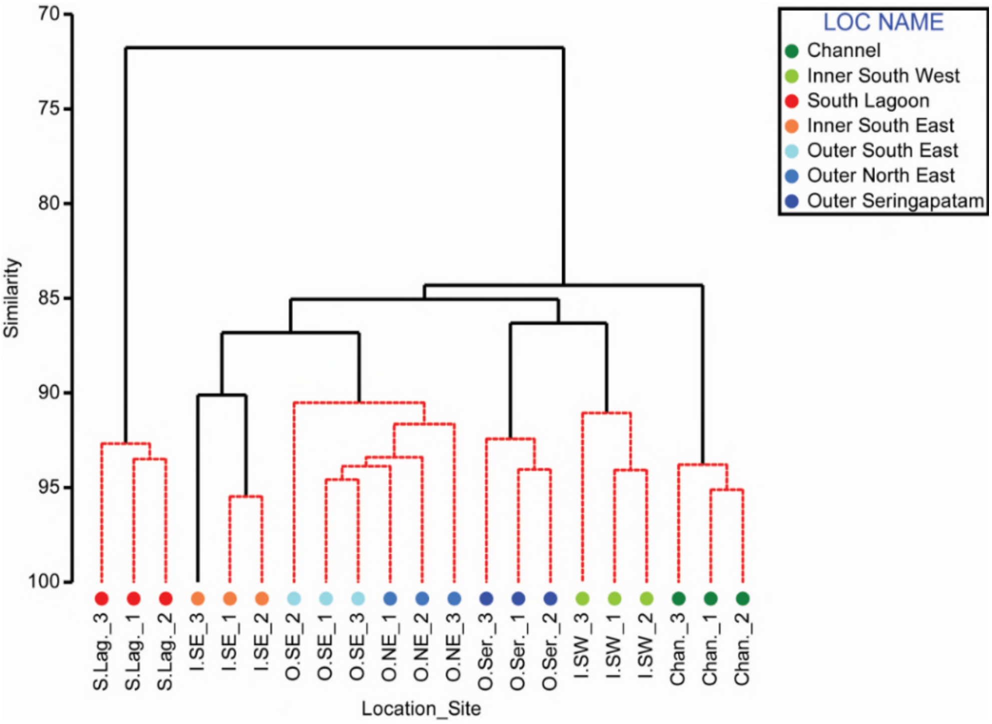

Figure A 1: Grouping of the long-term monitoring sites surveyed at the Scott Reef system over the study period 1994 – 2014 based on similarities in benthic community structure. Spatial variation in the structure of coral communities at Scott Reef (1994–2014). Replicate sites (n = 3) consistently grouped together within locations (Figure 1). Sites linked by red lines are not significantly different, according to the SIMPROF procedure at a significance level of 5%. Data are Bray Curtis similarities for Log+1 transformed percentage cover of benthic groups (Table 1).

Appendix 2

The physical parameters that best distinguished locations at Scott Reef were associated with their regimes of sedimentation, water temperatures and current speeds, winds and waves, and concentrations of chlorophyll and turbidity (**Figure A2**).

The outer-slope locations at South Reef (Outer South East) and North Reef (Outer North East) were exposed to the open ocean to the east but sheltered from monsoonal storms from the west, and had a sloping substrata with a low cover of sand; they experienced moderate variation in water temperatures, but with occasional increases in temperature at the Outer North East due to the flow of warm water out of the lagoon and over the reef flat in summer. The outer-slope locations had intermediate rates of sediment deposition spanning a range of particle sizes, moderate current velocities and exposure to moderate winds and waves from the east (**Figure A2**). Although not quantified, the routine habitat conditions at Outer Seringapatam were similar to Outer North East.

Among the inner-slope locations, habitat conditions varied according to their proximity to the sheltered lagoon in South Reef and to the western side of the deep channel between North and South Reef. The South Lagoon was by far the most sheltered, having the lowest exposure to winds and waves, the slowest current speeds, a low deposition of fine particle sizes (silt, clay) and relatively high turbidity and chlorophyll concentrations. Consequently, its community experienced moderate temperature variation and was characterised by a fragile and gently sloping substrata with a low cover of sand.

Inner South West and Channel locations were the most exposed to winds and waves generated by seasonal storms from a westerly, south-westerly direction, and had high maximum current speeds and wave heights in summer (**Figure A2a, A2c**). Both locations had a high cover of sand, a high deposition of larger particle sizes (sand, coarse sand), and a low concentration of chlorophyll and turbidity. The Inner South West and Channel both had large temperature ranges and the highest 'cooling index' of all locations (**Figure A2a, A2b**). The Channel had steep substrata, while Inner South West was comparatively flat with patchy coral outcrops. Conditions at Inner South East were a mixture of the other locations, being exposed to winds, waves and cool water through the channel from the west, while also being sheltered from the open ocean to the east.

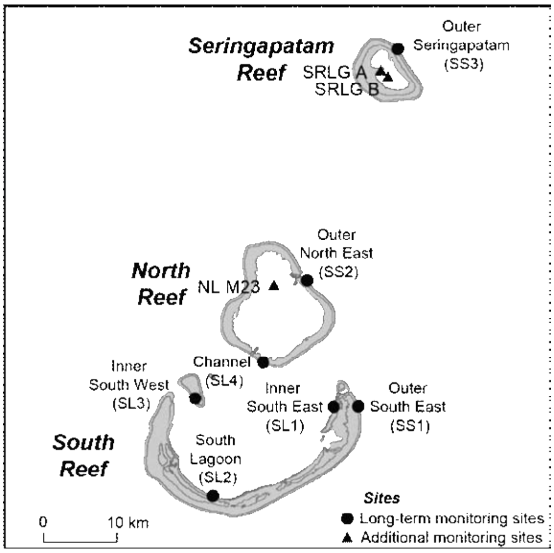

Figure A 2: (a) Location of monitoring sites at Scott Reef. Long-term monitoring sites (black circles) have been surveyed since 1994 and additional monitoring sites (black triangles) since 2016

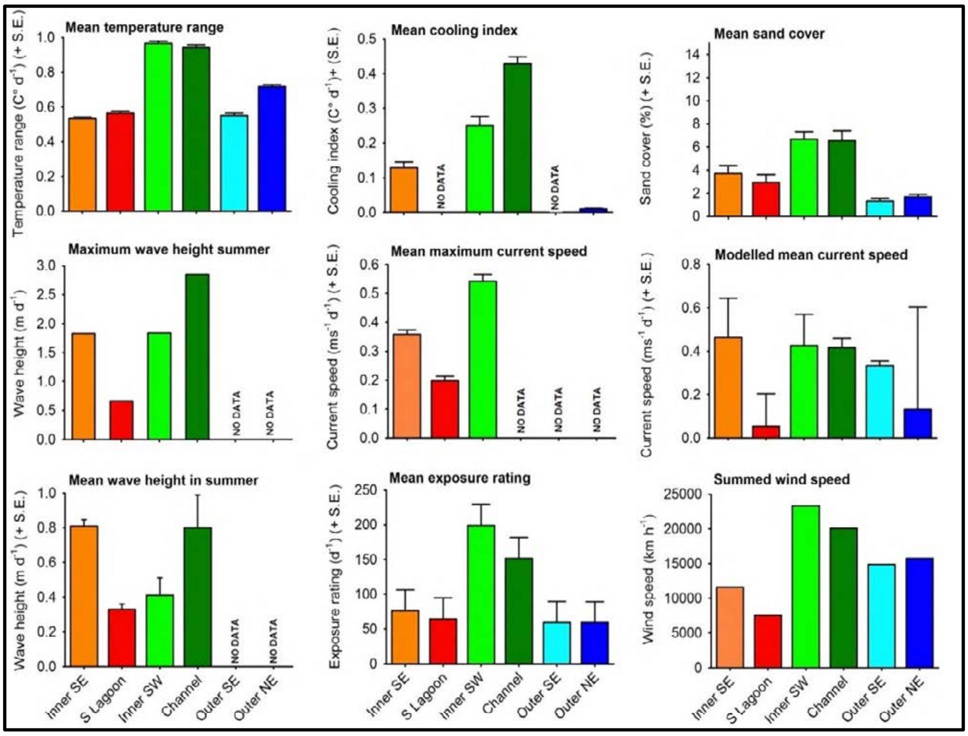

Figure A 2: (b) Physical parameters measured at the long-term monitoring locations at Scott Reef. (c) Seasonal variation in physical parameters long-term monitoring locations at Scott Reef.

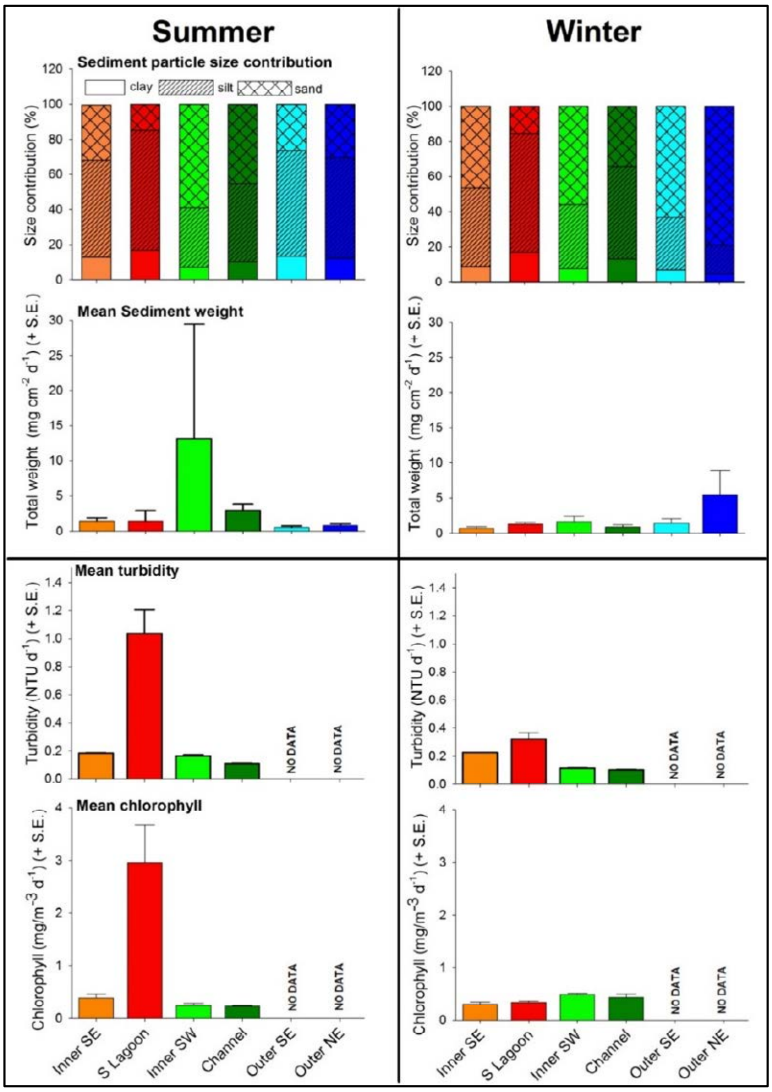

Figure A 2: (c) Seasonal variation in physical parameters long-term monitoring locations at Scott Reef.

Appendix 3

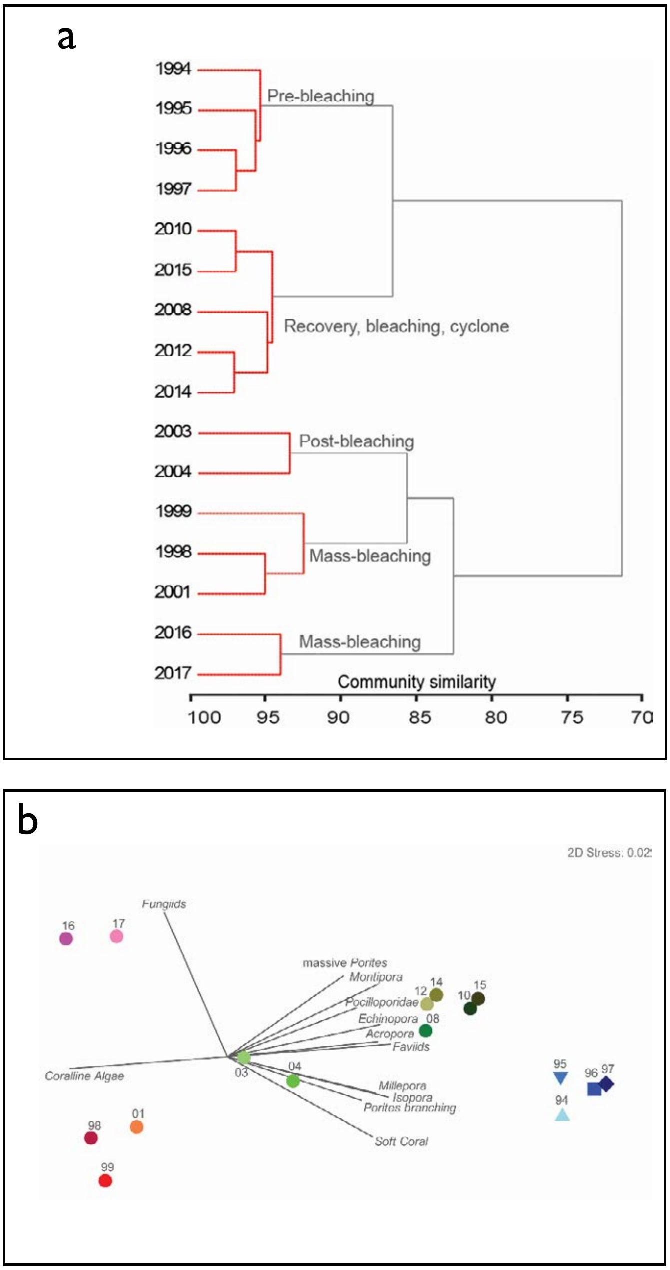

Figure A 3: Temporal variation in community structure across Scott Reef grouped into five distinct periods, according to the cycles of impact and recovery from multiple disturbances, which were indicative of the state of the reef. a) Dendrogram showing years when coral community structure varied significantly (grey lines) across Scott Reef, according to the SIMPROF procedure at a significance level of 5%. Data are Bray Curtis similarities for Log + 1 transformed percentage cover of benthic groups. (b) Grouping of coral communities among years according to their differences in structure, with vectors indicating which coral groups are most abundant during the nearest years and distinguish communities from other years. Non-metric Multidimensional Scaling of coral community structure, using Bray-Curtis similarities of percentage cover of coral groups (square root transformed) by survey year.

Appendix 4

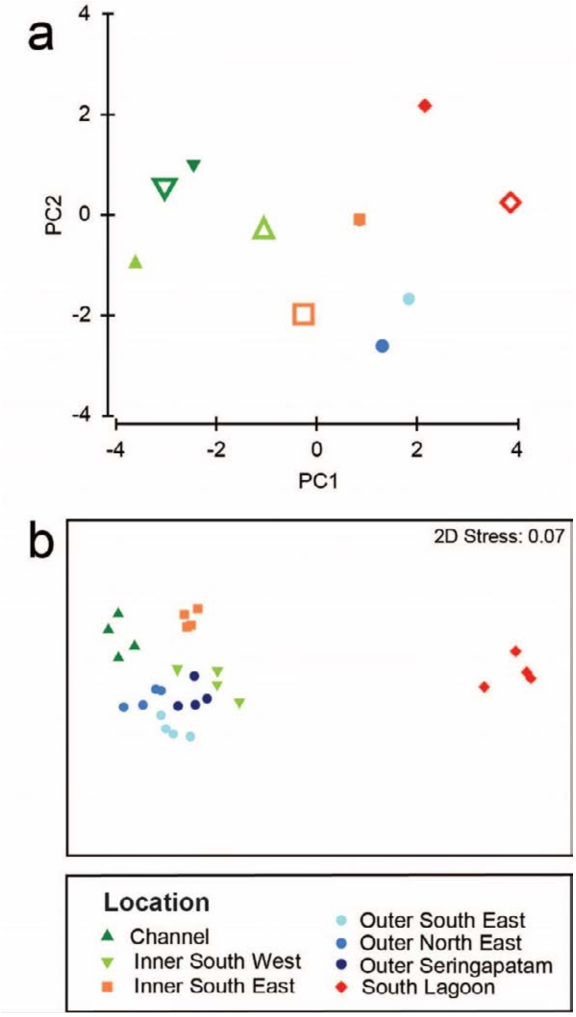

Figure A 4: Physical conditions varied among locations across Scott Reef and caused comparable variation in coral community structure. (a) Principal Coordinate Analyses showing variation in physical conditions among locations (solid symbols) at North and South Reef, and additional parameters quantified only at the inner slope locations (hollow symbols). Physical conditions and their contribution to differences among location are in Appendix 1 and Appendix 5. (b) Non-metric Multidimensional Scaling, illustrating comparable variation in coral community structure among locations, during pre-bleaching (1994-1997) when the influence of physical conditions was not confounded by severe disturbances. Data are Bray-Curtis similarities of percentage cover of coral groups (square root transformed).

Appendix 5

Table A 5: Variation in habitat conditions among locations at Scott Reef. Results of principal component analysis (PCA) of 10 variables quantified at all locations, and an additional 10 variables quantified at only the inner slope locations. Data for most parameters were first converted to daily averages and divided between summer (sum.) and winter (win.) months. More detailed parameter descriptions are in Table 2. Values indicate the strength of the correlation coefficient for each variable with the eigenvector of each PC. The first principle component (PC1) accounts for most of the variation among locations, and the contribution (positive, negative) of each parameter is ranked below each principle component.

All locations				**Inner slope locations**			
Principal Component	Eigenvalue	%Var.	Cum.%Var.	Principal Component	Eigenvalue	%Var.	Cum.%Var.

Appendix 6

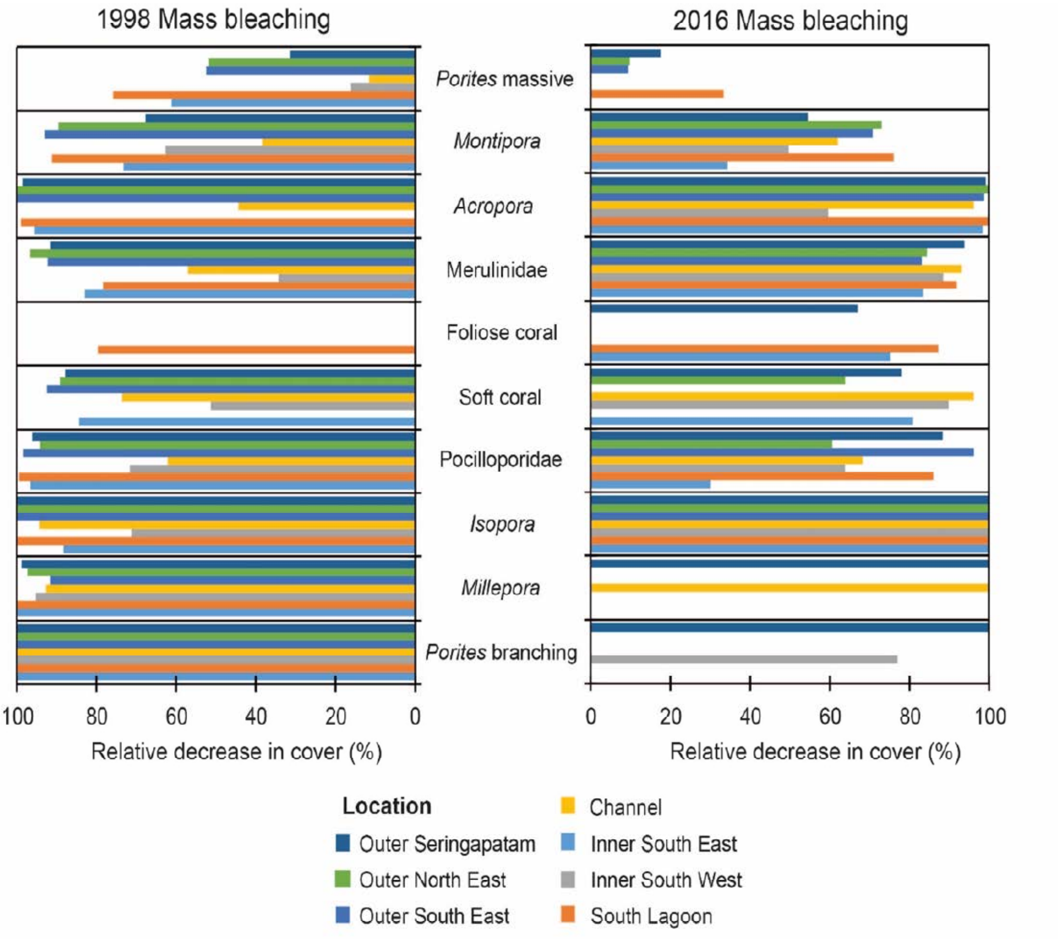

Figure A 6: The variable impact of mass bleaching in 1998 and 2016 among coral groups and locations at Scott Reef. The mean (± SE) relative decreases (%) in coral cover before (October 1997, January 2016) and after (October 1998, October 2016) mass bleaching in March/April. Coral groups and locations were included only if their mean pre-bleaching cover was > 1%, as estimates of relative change are not accurate for rare corals. Not all coral groups were common (> 1%) at all sites prior to the mass bleaching in 1998 (e.g. Foliose corals), and others were rare prior to the mass bleaching in 2016 because they had not recovered from the 1998 mass bleaching (e.g. *Porites* branching, *Millepora,* Soft Coral). Coral groups are in Table 1 and locations in Figure 1.

Appendix 7

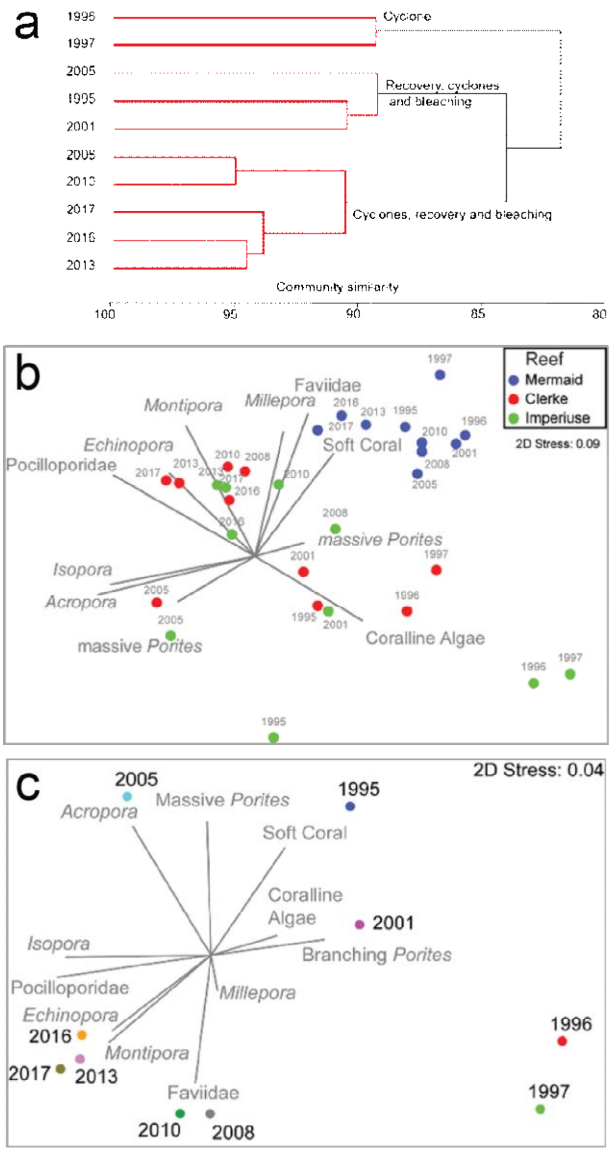

Figure A 7: Temporal variation in community structure across the Rowley Shoals grouped into three distinct periods, according to the cycles of impact and recovery from multiple disturbances. a) Dendrogram showing years when coral community structure varied significantly (black lines) across Rowley Shoals, according to the SIMPROF procedure at a significance level of 5%. Data are Bray Curtis similarities for Log + 1 transformed percentage cover of benthic groups. The grouping of coral communities among years b) at each reef, and c) averaged across all reefs, according to their differences in structure. Vectors indicate which coral groups are most abundant at the nearest reefs and/or years and distinguish communities from other reefs and/or years. Non-metric Multidimensional Scaling of coral community structure, using Bray-Curtis similarities of percentage cover of coral groups (square root transformed) by survey year.

Executive Summary

The Browse Joint Venture (BJV) proposes to develop the Brecknock, Calliance, and Torosa fields (collectively known as the Browse resources) via the development drilling of wells and the installation of subsea production system that will supply two 1100 Million standard cubic feet per day (annual daily export average) Floating Production Storage and Offloading (FPSO) facilities. The Browse to North West Shelf (NWS) Project gas will be transported from the FPSO facilities to the existing North West Shelf (NWS) Project infrastructure via a ~900 km trunkline. Each FPSO will have a turret mooring system that will be stabilised using mooring lines secured to the seabed by piles. These piles may have to be installed using impact piling methods.

Underwater noise will be generated during the following activities considered in this modelling study:

- The installation of one subsea FPSO mooring pile per day through impact piling using either a medium or high power hammer,
- The operations of a Mobile Offshore Drilling Unit (MODU),
- Vertical Seismic Profiling (VSP) during drilling operations,
- FPSO operational noise for Torosa and Brecknock FPSO's under normal operating conditions and with Dynamic Positioning (DP) operating,
- FPSO operational noise during offtake, including the FPSO under DP, an Offshore Support Vessel (OSV) near each FPSO (presented in isolation also) and a noiseless condensate tanker, and
- Aggregate scenarios which include FPSOs under normal operating conditions (without DP), as well as offtake operations at both locations simultaneously.

The objective of the modelling study was to determine ranges to acoustic exposure thresholds representing the best available science for potential injury, temporary threshold shift (TTS), and behavioural disturbance of marine fauna including marine mammals, turtles, and fish. For pygmy blue whales and green turtles during pile driving, an additional objective of this modelling study was to predict the number of animals that may be exposed to sound levels that could result in permanent threshold shift (PTS), TTS, or behavioural disturbance.

Acoustic fields caused by pressure were modelled and are presented as sound pressure levels (SPL), zero-to-peak pressure levels (PK), and either single-impulse (i.e., per-strike, per-pulse) or accumulated sound exposure levels (SEL) as appropriate for different noise effect criteria for either continuous (vessels) or impulsive (piling and VSP) noise sources. The effects of range-dependent environmental properties on sound propagation in the study area were accounted for by the numerical models.

For pygmy blue whales and green turtles, the JASCO Animal Simulation Model Including Noise Exposure (JASMINE) was used to integrate the sound fields with species-specific behaviour. JASMINE results provide an estimate of the probability of sound exposure, which can be compared to acoustic thresholds and then scaled to estimate the number of animals expected to receive sound levels that may cause PTS, TTS or behavioural disturbance. To assist with exposure modelling, a modified Biologically Important Area (BIA) for inter-nesting green turtles and a migrating area were considered, along with the pygmy blue whale BIAs for migrating and foraging.

FPSO Anchor Pile Installation

The predicted distances to all per-strike isopleths (contours of equal sound level) are farthest from the piles at the start of piling, when most of the pile remains in the water column, and shortest at the end of piling, when most of the pile is buried in the sediment. This is despite the increased frictional resistance of sediments and stronger stress-wave reflections at the pile toe at later stages of insertion.

For exposure criteria based on SEL_{24h} metrics, the ranges must be considered in context of the duration of operations. The modelling assumed one pile will be driven per day; therefore, the corresponding sound level is denoted as SEL_{24h}; however, the estimated times for driving piles are 78.5 or 45.5 minutes (Torosa) and 80.1 or 47.4 minutes (Brecknock) for medium and high-power hammers, respectively. SEL_{24h} is a cumulative metric that reflects the dosimetric impact of noise levels within the driving period, assuming that an animal is consistently exposed to such noise levels at a fixed position. The radii that correspond to SEL_{24h} typically represent an unlikely worst-case scenario for SEL-based exposure because, more realistically, marine fauna (mammals or fish) would not stay in the same location or at the same distance from a sound source for an extended period. Therefore, a reported radius for SEL_{24h} criteria does not mean that any animal travelling within this radius from the source *will* be exposed to PTS or TTS, but rather that it *could* be exposed if it remained within that range for the entire duration of the pile driving.

Animal Movement and Exposure Modelling

To present more biologically relevant results, JASMINE was applied for pygmy blue whales and green turtles. The potential risk of acoustic exposure for these species was estimated by finding the accumulated SEL and maximum PK or SPL each simulated animal (animat) received over the duration of the simulation, using acoustic exposure thresholds representing the best available science for PTS, TTS, and behavioural disturbance. The results include the range within which 95% of the exposure exceedances occur (95th percentile ranges, P_{95}) and the projected number of individual animals exposed to sound levels above threshold values. The number of individuals was determined by scaling the number of animats exposed above threshold in the simulation using available density data and considering the relevant BIAs. The modelling considered the behaviour of pygmy blue whales while migrating and foraging, and green turtles while inter-nesting and migrating. For migratory green turtles, no density data were available, so results are presented in terms of 95th percentile ranges only. Mitigation of potential impacts through exclusion zones for pygmy blue whales and turtles (2000 and 500 m, respectively) were considered in the modelling.

Torosa Location

The number of green turtle exposures above PTS PK or PTS SEL_{24h} thresholds was zero, regardless of hammer type. The number of pygmy blue whale exposures above PTS PK was zero, and there were between 0.02 and 0.03 migrating or foraging pygmy blue whale exposures above the PTS SEL_{24h} threshold for either hammer without mitigation.

No inter-nesting green turtle animats were predicted to be exposed above threshold levels for PTS or TTS for either hammer. Densities were not available for migratory turtles; however, no turtle animats were predicted to be exposed to noise levels above PTS PK, PTS SEL_{24h}, or TTS PK thresholds. No migratory pygmy blue whales were predicted to be exposed to noise above PTS PK or TTS PK thresholds. With exclusion zones in place, exposures to injury threshold criteria for both species and both hammers were reduced to zero. TTS SEL_{24h} was still predicted to occur, with no substantial change to exposure numbers. This is because a large proportion of animats exposed above that threshold occurred at ranges greater than the exclusion zones.

The overall potential for behavioural impacts is also predicted to be low for both species. None are predicted for inter-nesting green turtles. While no real-world densities for migratory green turtles are available, the 95th percentile ranges for the most conservative case (the high power hammer and the 166 dB SPL behavioural response threshold) were between 2.54 and 4.64 km from the pile. The number of individual pygmy blue whales predicted to be exposed to noise levels exceeding the behavioural threshold was between 0.56 and 1.41 individuals, depending upon the hammer size.

Applying exclusion zones had less influence on exposures above behavioural thresholds. Ranges associated with migrating green turtles showed no substantial change, except that all animats exposed to the 175 dB SPL behavioural disturbance threshold, which were within 50 m of the pile, were removed from consideration. Therefore, the application of the exclusion zone reduced the number of animats exposed above threshold by 100%, or to zero. Both foraging and migrating pygmy blue whale exposures above the 160 dB SPL threshold, for both hammers, decreased slightly.

Brecknock Location

Results predicted that green turtles were unlikely to be exposed the noise above threshold levels for PTS, TTS, or behavioural disturbance, even without applying a 500 m exclusion zone. This is because the Brecknock pile location is more than 40 km from either the modified inter-nesting or migration area BIAs.

With no exclusion zone, pygmy blue whales were not exposed to noise levels above PTS PK or TTS PK for either hammer, exposures above the threshold for PTS SEL$_{24h}$ ranged from 0.02–0.04 for either the medium or high powered hammer, respectively. TTS SEL$_{24h}$ exposures for migrating blue whales ranged from 1.56–1.67 for either the medium or high powered hammer, respectively. The number of predicted exposures above TTS SEL$_{24h}$ threshold for foraging pygmy blue whales was much lower than for migrating pygmy blue whales because the Brecknock piling location is 10.3 km from the foraging BIA.

With the 2000 m exclusion zone in place, PTS SEL$_{24h}$ exposures reduced to zero for either hammer. The number of predicted exposures for foraging pygmy blue whales did not change as a result of applying an exclusion zone because of the large distance to the BIA.

Torosa and Brecknock Ranges to Exposure Thresholds

The analysis considered multiple effects criteria commonly used in pile driving noise assessments. Key results of the acoustic modelling are summarised below.

Marine Mammals

- United States National Marine Fisheries Service (NMFS 2014) acoustic threshold for behavioural effects in cetaceans: Pile driving impulse sounds are predicted to exceed the SPL threshold of 160 dB re 1 µPa for behavioural effects of marine mammals within 10.48 or 17.15 km (Torosa), or 7.06 or 13.97 km (Brecknock), of the pile (medium and high power hammer, respectively), are associated with the shallowest penetration of 17 m for both hammers.
- The results for the NMFS (2018) criteria applied for marine mammal PTS and TTS consider both metrics within the criteria (PK and SEL), with SEL assessed here for a single pile within a 24 h period, i.e., a single pile per day. The metric with the longest distance must be applied, and these maximum distances along with the relevant metric are summarised in Table 1.

Table 1. *Marine mammal injury and hearing sensitivity changes*: Maximum-over-depth distances (in km) from the pile to PTS and TTS thresholds (NMFS 2018).

Hearing group	PTS				TTS			
	IHC S-600		IHC S-1200		IHC S-600		IHC S-1200

† PK (L_{pk}; dB re 1 µPa)

Frequency weighted SEL$_{24h}$ ($L_{E,24h}$). For the SEL$_{24h}$ criteria, the model does not account for shutdowns.

Turtles

- The maximum distances to the two criteria considered in relation to turtle behaviour, behavioural response and disturbance, are associated with the shallowest penetration of 17 m for both hammers, with the maximum distances summarised in Table 2.
- The results for the Finneran et al. (2017) criteria applied for turtle PTS and TTS consider both metrics within the criteria (PK and SEL), with SEL assessed here for a single pile within a 24 h period, i.e., a single pile per day. The metric with the longest distance must be applied, and these maximum distances along with the relevant metric are summarised in Table 3.

Table 2. *Turtle behaviour*: Maximum (R_{max}) and 95% ($R_{95\%}$) horizontal distances (in km) from the pile to modelled maximum-over-depth behavioural response thresholds, maximum across all three penetration depths.

SPL (L_p; dB re 1 µPa)	**IHC S-600**		**IHC S-1200**	
	R_{max} (km)	$R_{95\%}$ (km)	R_{max} (km)	$R_{95\%}$ (km)
Torosa				
175†	0.68	0.64	1.87	1.79
166‡	5.11	4.99	9.11	5.66
Brecknock				
175†	0.67	0.63	1.87	1.77
166‡	2.87	2.70	6.38	5.92

† Threshold for turtle behavioural response to impulsive noise (McCauley et al. 2000a, 2000b).
‡ Threshold for turtle behavioural response to impulsive noise (NSF 2011).

Table 3. *Turtle injury and hearing sensitivity changes*: Maximum-over-depth distances (in km) from the pile to turtle PTS and TTS thresholds (Finneran et al. 2017).

Hearing group	**PTS**				**TTS**			
	IHC S-600		**IHC S-1200**		**IHC S-600**		**IHC S-1200**	
	R_{max} (km)	$R_{95\%}$ (km)	R_{max} (km)	$R_{95\%}$ (km)	R_{max} (km)	$R_{95\%}$ (km)	R_{max} (km)	$R_{95\%}$ (km)
Torosa								
Turtles	0.24	0.23	0.25	0.25	4.79	2.36	5.07	4.94
Brecknock								
Turtles	0.24	0.23	0.25	0.24	2.58	2.44	2.60	2.47

All distances are associated with frequency weighted SEL$_{24h}$ ($L_{E,24h}$; dB re 1 µPa^2·s), not PK (L_{pk}; dB re 1 µPa). For the SEL$_{24h}$ criteria, the model does not account for shutdowns.

Fish, Fish Eggs, and Fish Larvae

- The modelling study assessed the ranges for quantitative criteria from Popper et al. (2014) associated with mortality and potential mortal injury and impairment (as defined in the criteria) in the following:
    - Fish without a swim bladder (also appropriate for sharks in the absence of other information)
    - Fish with a swim bladder not used for hearing
    - Fish that use their swim bladders for hearing
    - Fish eggs, and fish larvae
- The distance from pile driving at which sound levels exceeded mortality and potential mortal injury for the most sensitive fish groups from the piles was as follows for the medium or high-powered hammer, respectively:
    - Torosa, 210 or 220 m (SEL_{24h} metric),
    - Brecknock, 200 or 220 m (SEL_{24h} metric)
- Fish (including sharks) could experience TTS from the proposed pile driving activity. It is predicted that this will occur within the following distances of the pile for the medium or high-powered hammer, respectively:
    - Torosa, 9.05 or 9.15 km
    - Brecknock, 6.12 or 6.27 km

Vertical Seismic Profiling

The modelling scenarios for VSP considered a single 750 in^3 array suspended at 6 m at the MODU location at both Torosa TRD Well and Brecknock, and these scenarios assessed both individual impulses and multiple impulses within a 24 h period to determine SEL_{24h}.

The analysis considered multiple effects criteria commonly used in seismic survey noise assessments. Key results of the acoustic modelling are summarised below.

Marine mammals

- The maximum distance where the NMFS (2014) marine mammal behavioural response criterion of 160 dB re 1 µPa (SPL) could be exceeded varied between 1.6 and 1.7 km, with the distance being longer at Brecknock.
- The results for the criteria applied for marine mammal PTS, NMFS (2018), consider both metrics within the criteria (PK and SEL_{24h}), and a range of impulses within 24 h, from 1 to 150. The applicable metric from the criteria, associated with the longest distance associated with either metric, depends upon the number of impulses with the 24 h. The ranges presented are based upon no more than 150 impulses within 24 h.

  PTS and TTS are not predicted to occur in mid-frequency cetaceans. For PTS in high-frequency cetaceans, the PK metric is always associated with the longest range (68 m), while for PTS in low-frequency cetaceans, for less than 10 impulses the range is greater due to the PK metric (12 m), but otherwise the range is determined by SEL_{24h}, with the maximum distance of 200 m being associated with 150 impulses at either Torosa TRD Well or Brecknock.

  For TTS in high-frequency cetaceans the PK metric is always associated with the longest range (141 m), while for TTS in low-frequency cetaceans the range is determined by SEL_{24h}, with the maximum distance of 1.69 km for 150 impulses at Torosa TRD Well or Brecknock.

Turtles

- The VSP source is not predicted to cause PTS in turtles, as it doesn't cause either the PK or SEL_{24h} criteria from Finneran et al. (2017) to be exceeded at a distance greater than the horizontal modelling resolution (20 m) from the source.

As with marine mammals, the SEL_{24h} considers a range of impulses within 24 h, from 1 to 150. While the TTS criteria due to the PK metric isn't exceeded, depending upon the number of impulses, the TTS SEL_{24h} criteria can be exceeded at up to 160 m for 150 impulses at Torosa TRD Well or Brecknock.

- The distances at where the two criteria considered in relation to turtle behaviour, behavioural response and disturbance could be exceeded are summarised in Table 4.

Table 4. *Turtle behaviour*: Distances to behavioural response criteria for VSP.

SPL (**L_p; dB re 1 µPa**)	**R_{max} (km)**	**$R_{95\%}$ (km)**
Torosa TRD Well		
175†	0.23	0.23
166‡	0.81	0.77
Brecknock		
175†	0.23	0.23
166‡	0.72	0.69

† Threshold for turtle behavioural response to impulsive noise (McCauley et al. 2000a, 2000b).
‡ Threshold for turtle behavioural response to impulsive noise (NSF 2011).

Fish, fish eggs, and fish larvae

- This modelling study assessed the ranges for quantitative criteria based on Popper et al. (2014) and considered both PK (seafloor and water column) and SEL_{24h} metrics associated with mortality and potential mortal injury and impairment in the groups listed in the piling section
- The distance from pile driving at which sound levels exceeded mortality and potential mortal injury for the most sensitive fish groups was 40 m (PK metric).
- Sound levels at the seafloor do not exceed any of the fish criteria, and SEL_{24h} metrics for injury were not exceeded in the water column

Sponges and Coral

- To assist with assessing the potential effects on sponges and coral receptors, the PK sound level at the seafloor directly underneath the VSP source was estimated at both modelling sites. It was found that the sound level of 226 dB re 1 µPa PK, a sound level associated with no effect (Heyward et al. 2018) was not reached.

Vessel Operations

The modelled scenarios for vessels consider the following sources or scenarios:

- Two FPSO facilities 370 m long and 67 m wide, both under typical operations, with no thrusters and no offtake, only topsides equipment, and under dynamic positioning representative of typical operational loads during moderate weather conditions;
- A representative OSV, a dynamic positioning Class 2 (DP2) vessel within 700 m of each FPSO under dynamic positioning representative of typical operational loads during moderate weather conditions;
- A representative MODU that is 100 × 80 m under dynamic positioning, representative of typical operational loads during moderate weather conditions;
- FPSO operational noise during offtake, including the FPSO under DP, an Offshore Support Vessel (OSV) near each FPSO (presented in isolation also) and a noiseless condensate tanker, and
- Aggregate scenarios which include FPSOs under normal operating conditions (without DP), as well as offtake operations, at both locations simultaneously.

The analysis considered multiple effects criteria commonly used, with key results of the acoustic modelling are summarised below.

Marine mammals

- The results for the NMFS (2018) criteria applied for marine mammal PTS and TTS for vessels are assessed here for a 24 h period. The maximum distances to PTS are summarised in Table 5.
- The maximum distances to the NMFS (2014) marine mammal behavioural response criterion of 120 dB re 1 µPa (SPL) are summarised in Table 6.
- For aggregate scenarios considering both FPSO's, it was found that due to the separation between the sites, distances to PTS, TTS, and behavioural thresholds remained unaltered compared to the individual operations. This was quantified by verifying that the total aggregate area within threshold isopleth for marine mammal behavioural response to continuous noise (NMFS 2014) area equals the sum of the areas for the individual operations.

Table 5. *Marine mammal injury*: Maximum (R_{max}) horizontal distances (km) to modelled maximum-over-depth PTS thresholds from NMFS (2018) for vessel-based scenarios.

Hearing group	**Threshold for PTS, SEL_{24h} (dB re 1 µPa²·s)** [#]	**Distance R_{max} (km)**

FPSO offtake includes an FPSO under DP, a noiseless condensate tanker and an OSV.

Turtles

- The results for the Finneran et al. (2017) criteria applied for turtle PTS for vessel-based scenarios are assessed here for a 24 h period, and the maximum distances are summarised in Table 7.

Table 7. *Turtle injury*: Maximum-over-depth distances (in km) to PTS threshold (Finneran et al. 2017) for vessel-based scenarios.

SEL_{24h} ($L_{E,24h}$; dB re 1 µPa²·s)	Distance R_{max} (km)				
	MODU	OSV	FPSO on DP	FPSO without DP	FPSO offtake
Torosa					
220†	0.06	0.06	<0.02	-	<0.02
Brecknock					
220†	0.06	0.06	<0.02	-	<0.02

† Threshold for turtle-weighted SEL_{24h} (Finneran et al. 2017).
A dash indicates the level was not reached.
FPSO offtake includes an FPSO under DP, a noiseless condensate tanker and an OSV.

Fish

- Sound produced by the vessel operations could cause physiological effects, and recoverable injury, to some fish species, but only if the animals are in very close proximity to the sound sources–within a planar distance of 60 m, for 48 h. Temporary impairment due to TTS could occur at similar short distances if fish remain at the same point within the sound field for long periods of time (12 h). The distances are farther for the MODU, and smallest for the FPSO without DP.
- For offtake operations, recoverable injury and temporary impairment could happen if fish remain within planar distances of <20 m and 40 m, respectively, from the FPSO or the OSV thrusters.
- There is no increased risk to fish from aggregate scenarios, with ranges to thresholds from the individual sources unchanged.

1. Introduction

JASCO Applied Sciences (JASCO) performed a modelling study of underwater sound levels associated with the Browse to North West shelf (NWS) Project development of the Brecknock, Calliance, and Torosa fields (collectively known as the Browse resources) by the Browse Joint Venture (BJV). This will involve the development drilling of wells and the installation of subsea production system that will supply two 1100 Million standard cubic feet per day (annual daily export average) Floating Production Storage and Offloading (FPSO) facilities. Gas will be transported from the FPSO facilities to the existing North West Shelf (NWS) Project infrastructure via a ~900 km trunkline. Each FPSO will have a turret mooring system that will be stabilised using mooring lines secured to the seabed by piles.

The modelling study considers:

- The installation of a single subsea FPSO mooring pile per day through impact piling using either a medium or high power hammer;
- The operations of a Mobile Offshore Drilling Unit (MODU);
- Vertical Seismic Profiling (VSP) during drilling operations;
- FPSO operational noise for Torosa and Brecknock FPSO’s under normal operating conditions and with Dynamic Positioning (DP) operating;
- FPSO operational noise during offtake, including the FPSO under DP, an Offshore Support Vessel (OSV) near each FPSO (presented in isolation also) and a noiseless condensate tanker; and
- Aggregate scenarios which include FPSOs under normal operating conditions (without DP), as well as offtake operations at both locations simultaneously.

The modelling study specifically assessed distances from operations where underwater sound levels reached thresholds corresponding to various levels of impact to marine fauna. The animals considered here included marine mammals (pygmy blue whales, *Balaenoptera musculus brevicauda*), turtles, and fish (including fish eggs and larvae). Due to the variety of species considered, there are several different thresholds for evaluating effects, including: mortality, injury, temporary reduction in hearing sensitivity, and behavioural disturbance.

The modelling methodology considered source directivity and range-dependent environmental properties. Estimated underwater acoustic levels are presented as sound pressure levels (SPL, L_p), zero-to-peak pressure levels (PK, L_{pk}), and either single-impulse (i.e., per-strike) or accumulated sound exposure levels (SEL, L_E) as appropriate for different noise effect criteria for either continuous (vessels) or impulsive (piling and VSP) noise sources.

In addition to the propagation modelling, this report describes the modelled predictions of sound levels that individual animals may receive during the operations. Sound exposure distribution estimates for pygmy blue whales and green turtles (*Chelonia mydas*) to pile driving operations are determined by moving large numbers of simulated animals through a modelled time-evolving sound field, computed using specialised sound source and sound propagation models. This approach provides the most realistic prediction of the maximum expected SPL, PK, and the temporal accumulation of SEL that are considered the most relevant sound metrics for impact assessment. The most recent science in the peer-reviewed literature regarding sound propagation and animal movement modelling was used.

The geographic coordinates for the modelled sites are provided in Table 8 and an overview of the modelling area is shown in Figure 1.

Table 8. Location details for the modelled sites.

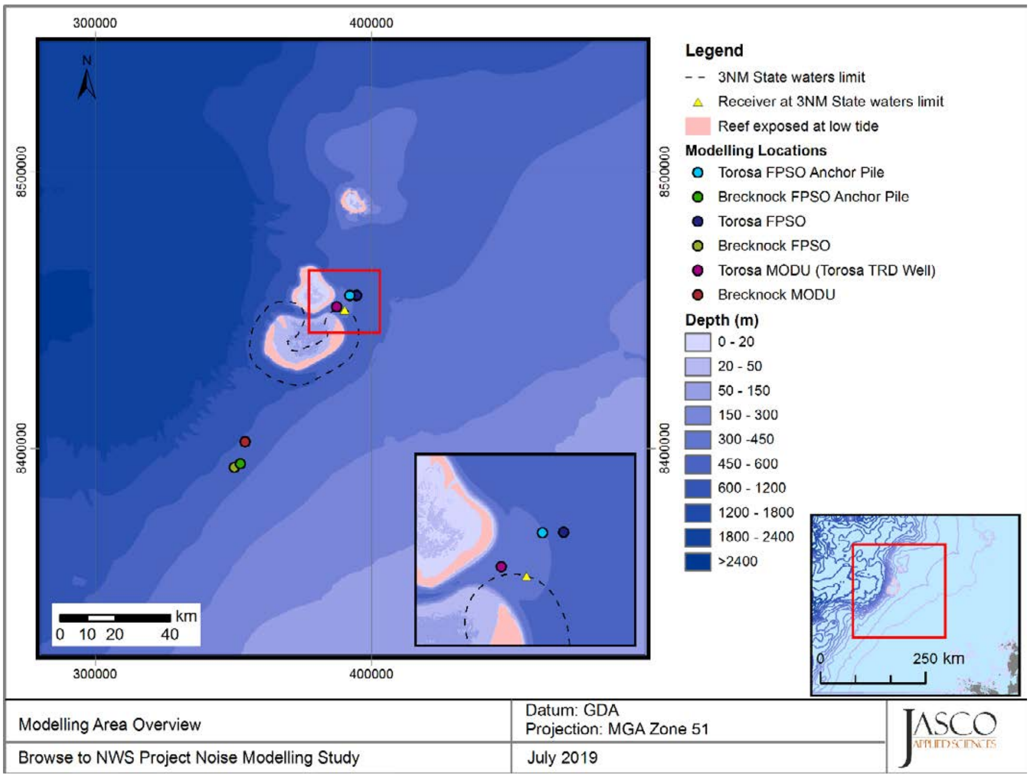

Figure 1. Overview of the modelled area and local features.

1.1. Acoustic Modelling Scenario Details

The modelling scenario for pile driving of the Torosa FPSO anchor pile (Section 3.4) considers a pile 53.25 m long, 5.5 m in diameter with 60 mm thick walls, driven a total of 51.5 m into the seabed. Two pile driving hammers were considered in this study: the IHC S-600 with 600 kJ per-strike energy and the IHC S-1200 with 1200 kJ. The modelling assumed one pile will be driven per day; therefore, while the corresponding sound level is denoted SEL_{24h}, the period of accumulation considered in the scenario is determined based upon the estimated time for driving the single pile.

The modelled scenarios for vessels (Section 3.6) consider:

- Two FPSO facilities 370 m long and 67 m wide:
    - Both under typical operations, with no thrusters and no offtake, only topsides equipment;
    - Under dynamic positioning representative of typical operational loads during moderate weather conditions;
    - Under offtake, during which the FPSO is under DP, and an OSV under DP is located 700 m behind the FPSO, and a noiseless condensate tanker is between the FPSO and the OSV; and
    - Aggregate scenarios which include FPSOs under normal operating conditions (without DP), as well as offtake operations at both locations simultaneously.
- A representative OSV, a dynamic positioning Class 2 (DP2) vessel 87.08 m long, within 700 m of each FPSO under dynamic positioning representative of typical operational loads during moderate weather conditions.
- A representative MODU that is 100 × 80 m under dynamic positioning, representative of typical operational loads during moderate weather conditions.

The modelling scenarios for VSP (Section 3.5) consider a single 750 in^3 array suspended at 6 m at the MODU location at both Torosa TRD Well and Brecknock, and these scenarios assessed both individual impulses and up to 150 impulses within a 24 h period.

Table 9. Modelled receiver location for Torosa FPSO Anchor Piling

Sound field sampling location	Latitude (S)	Longitude (E)	MGA (GDA94), Zone 51		Relevant modelled scenario	Distance from sampling location to modelled site (km)	Water depth (m)
			X (m)	*Y* (m)			
3NM State waters limit	14° 01' 02.5404"	121° 59' 03.5282"	390318	8450117	Torosa FPSO anchor pile	5.41	414

2. Noise Effect Criteria

To assess the potential impacts of a sound-producing activity, it is necessary to first establish exposure criteria (thresholds) for which sound levels may be expected to have a negative impact on animals. Whether acoustic exposure levels might injure or disturb marine fauna is an active research topic. Since 2007, several expert groups have developed SEL-based assessment approaches for evaluating auditory injury, with key works including Southall et al. (2007), Finneran and Jenkins (2012), Popper et al. (2014), and United States National Marine Fisheries Service (NMFS 2018). The number of studies that investigate the level of behavioural disturbance to marine fauna by anthropogenic sound has also increased substantially.

Several sound level metrics, such as PK, SPL, and SEL, are commonly used to evaluate noise and its effects on marine life (Appendix A). In this report, the duration of the SEL accumulation is defined differently depending on the source considering, as per the following:

- For piling: As either a “per-strike” value (i.e., integrated over the time of a single strike), or over all strikes that occur over the driving of a single pile, one pile per 24 h time period.
- For VSP: As either a “per-pulse” value (i.e., integrated over the time of a single pulse), or over all impulses that occur in a 24 h time period.
- For vessels: Integrated over a 24 h time period.

Appropriate subscripts indicate any applied frequency weighting applied (Appendix A.3). The acoustic metrics in this report reflect the updated ANSI and ISO standards for acoustic terminology, ANSI S1.1 (R2013) and ISO 18405:2017 (2017).

This study applies the following noise criteria (Sections 2.1–2.2 and Appendix A.2), chosen for their acceptance by regulatory agencies and because they represent current best available science:

1. Peak pressure levels (PK; L_{pk}) and frequency-weighted accumulated sound exposure levels (SEL; $L_{\text{E,24h}}$) from the U.S. National Oceanic and Atmospheric Administration (NOAA) Technical Guidance (NMFS 2018) for the onset of permanent threshold shift (PTS) and temporary threshold shift (TTS) in marine mammals.
2. Marine mammal behavioural threshold based on the current interim U.S. National Marine Fisheries Service (NMFS) criterion NMFS (2014) for marine mammals of 160 dB re 1 µPa and 120 dB re 1 µPa SPL (L_{p}) for impulsive and non-impulsive sound sources, respectively.
3. Sound exposure guidelines for fish, fish eggs, and larvae (Popper et al. 2014).
4. Peak pressure levels (PK; L_{pk}) and frequency-weighted accumulated sound exposure levels (SEL; $L_{\text{E,24h}}$) from Finneran et al. (2017) for the onset of permanent threshold shift (PTS) and temporary threshold shift (TTS) in turtles.
5. Turtle behavioural response threshold of 166 dB re 1 µPa SPL (L_{p}) (NSF 2011), as applied by the US NMFS, along with a sound level associated with behavioural disturbance 175 dB re 1 µPa (SPL) (McCauley et al. 2000a, 2000b).

Additionally, for comparison to published literature, for VSP only, a sound level of 226 dB re 1 µPa PK (L_{pk}), a no effect sound level, is reported for comparing to Heyward et al. (2018) for sponges and corals.

2.1. Marine Mammals

The criteria applied in this study to assess possible effects of pile driving noise and vessel noise on marine mammals are summarised in Tables 10 and 11 and detailed in Sections 2.1.1 and 2.1.2, with frequency weighting explained in Appendix A.3.

Table 10. Acoustic effects of impulsive noise on marine mammals: Unweighted SPL, SEL$_{24h}$, and PK thresholds

Hearing group	NMFS (2014)	NMFS (2018)			
	Behaviour	**PTS onset thresholds* (received level)**		**TTS onset thresholds* (received level)**	
	SPL (L_p; dB re 1 µPa)	Weighted SEL$_{24h}$ ($L_{E,24h}$; dB re 1 µPa^2·s)	PK (L_{pk}; dB re 1 µPa)	Weighted SEL$_{24h}$ ($L_{E,24h}$; dB re 1 µPa^2·s)	PK (L_{pk}; dB re 1 µPa)
LF cetaceans	160	183	219	168	213
MF cetaceans		185	230	170	224
HF cetaceans		155	202	140	196

* Dual metric acoustic thresholds for impulsive sounds: Use whichever results in the largest isopleth for calculating PTS onset. If a non-impulsive sound has the potential of exceeding the peak sound pressure level thresholds associated with impulsive sounds, these thresholds should also be considered.
L_p denotes sound pressure level period.
$L_{pk,flat}$ denotes peak sound pressure is flat weighted or unweighted.
L_E denotes cumulative sound exposure over a 24 h period.

Table 11. Acoustic effects of continuous noise on marine mammals: Unweighted SPL and SEL$_{24h}$ thresholds.

Hearing group	NMFS (2014)	NMFS (2018)	
	Behaviour	**PTS onset thresholds (received level)**	**TTS onset thresholds (received level)**
	SPL (L_p; dB re 1 µPa)	Weighted SEL$_{24h}$ ($L_{E,24h}$; dB re 1 µPa^2·s)	Weighted SEL$_{24h}$ ($L_{E,24h}$; dB re 1 µPa^2·s)
LF cetaceans	120	199	179
MF cetaceans		198	178
HF cetaceans		173	153

L_p denotes sound pressure level period and has a reference value of 1 µPa.
L_E denotes cumulative sound exposure over a 24 h period and has a reference value of 1 µPa^{2}s.

2.1.1. Behavioural response

Numerous studies on marine mammal behavioural responses to sound exposure have not resulted in consensus in the scientific community regarding the appropriate metric for assessing behavioural reactions. However, it is recognised that the context in which the sound is received affects the nature and extent of responses to a stimulus (Southall et al. 2007, Ellison and Frankel 2012, Southall et al. 2016). Because of the complexity and variability of marine mammal behavioural responses to acoustic exposure, NMFS has not yet released technical guidance on behaviour thresholds for use in calculating animal exposures (NMFS 2018). The NMFS currently uses a step function to assess behavioural impact. A 50% probability of inducing behavioural responses at a SPL of 160 dB re 1 µPa was derived from the HESS (1999) report which, in turn, was based on the responses of migrating mysticete whales to airgun sounds (Malme et al. 1983, Malme et al. 1984). The HESS team recognised that behavioural responses to sound may occur at lower levels, but significant responses were only likely to occur above a SPL of 140 dB re 1 µPa. An extensive review of behavioural responses to sound was undertaken by Southall et al. (2007, their Appendix B). Southall et al. (2007) found varying responses for most marine mammals between a SPL of 140 and 180 dB re 1 µPa, consistent with the HESS (1999) report, but lack of convergence in the data prevented them from suggesting explicit step functions.

2.1.1.1. Impulsive noise

The absence of controls, precise measurements, appropriate metrics, and context dependency of responses (including the activity state of the animal) all contribute to the variability of the behavioural response of individuals. Therefore, unless otherwise specified, this study applied NMFS's relatively simple sound level criterion for potentially disturbing a marine mammal. For impulsive sounds, this threshold is 160 dB re 1 µPa SPL for cetaceans (NMFS 2014).

2.1.1.2. Continuous noise

The NMFS non-pulsed noise criterion was selected for this assessment because it represents the most commonly applied behavioural response criterion by regulators. The distances at which behavioural responses could occur were therefore determined to occur in areas ensonified above an unweighted SPL of 120 dB re 1 µPa (NMFS 2014).

2.1.2. Injury and hearing sensitivity changes

There are two categories of auditory threshold shifts or hearing loss: permanent threshold shift (PTS), a physical injury to an animal's hearing organs; and Temporary Threshold Shift (TTS), a temporary reduction in an animal's hearing sensitivity as the result of receptor hair cells in the cochlea becoming fatigued.

To assist in assessing the potential for effects to marine mammals, this report applies the criteria recommended by NMFS (2018), considering both PTS and TTS (Tables 10 and 11). Appendix A.2 provides more information about the NMFS (2018) criteria.

2.2. Fish, Turtles, Fish Eggs, and Fish Larvae

In 2006, the Working Group on the Effects of Sound on Fish and Turtles was formed to continue developing noise exposure criteria for fish and turtles, work begun by a NOAA panel two years earlier. The Working Group developed guidelines with specific thresholds for different levels of effects for several species groups (Popper et al. 2014). The guidelines define quantitative thresholds for three types of immediate effects:

- Mortality, including injury leading to death,
- Recoverable injury, including injuries unlikely to result in mortality, such as hair cell damage and minor haematoma, and
- TTS.

Masking and behavioural effects can be assessed qualitatively, by assessing relative risk rather than by specific sound level thresholds. However, as these depend upon activity-based subjective ranges, these effects are not addressed in this report and are included in Tables 12 and 14 for completeness only. Because the presence or absence of a swim bladder has a role in hearing, fish's susceptibility to injury from noise exposure depends on the species and the presence and possible role of a swim bladder in hearing. Thus, different thresholds were proposed for fish without a swim bladder (also appropriate for sharks and applied to whale sharks in the absence of other information), fish with a swim bladder not used for hearing, and fish that use their swim bladders for hearing. Turtles, fish eggs, and fish larvae are considered separately.

2.2.1. Impulsive noise

Impulsive noise from both piling and airguns (VSP) is assessed in this study, the relevant effects thresholds from Popper et al. (2014) are listed in Table 12. In general, whether an impulsive sound adversely effects fish behaviour depends on the species, the state of the individual exposed, and other factors.

The SEL metric integrates noise intensity over some period of exposure. Because the period of integration for regulatory assessments is not well defined for sounds that do not have a clear start or end time, or for very long-lasting exposures, an exposure evaluation time must be defined. Southall et al. (2007) defines the exposure evaluation time as the greater of 24 h or the duration of the activity. Popper et al. (2014) recommend a standard period of the duration of the activity; however, the publication also includes caveats about considering the actual exposure times if fish move. Integration times in this study for piling have been applied over the time a single pile was driven since only one pile is expected to be driven per day, while for VSP operations it is over the total number of impulses per day.

Table 12. Criteria for pile driving and seismic noise exposure for fish, adapted from Popper et al. (2014).

Type of animal	**Mortality and Potential mortal injury**	**Impairment**			**Behaviour**
		Recoverable injury	TTS	Masking	
Fish: No swim bladder (particle motion detection)	> 219 dB SEL$_{24\text{h}}$ or > 213 dB PK	> 216 dB SEL$_{24\text{h}}$ or > 213 dB PK	>> 186 dB SEL$_{24\text{h}}$	Pile driving: (N) Moderate (I, F) Low Seismic: (N, I, F) Low	(N) High (I) Moderate (F) Low
Fish: Swim bladder not involved in hearing (particle motion detection)	210 dB SEL$_{24\text{h}}$ or > 207 dB PK	203 dB SEL$_{24\text{h}}$ or > 207 dB PK	>> 186 dB SEL$_{24\text{h}}$	Pile driving: (N) Moderate (I, F) Low Seismic: (N, I, F) Low	(N) High (I) Moderate (F) Low
Fish: Swim bladder involved in hearing (primarily pressure detection)	207 dB SEL$_{24\text{h}}$ or > 207 dB PK	203 dB SEL$_{24\text{h}}$ or > 207 dB PK	186 dB SEL$_{24\text{h}}$	Pile driving: (N, I) High (F) Moderate Seismic: (N, I) Low (F) Moderate	(N, I) High (F) Moderate
Fish eggs and fish larvae	> 210 dB SEL$_{24\text{h}}$ or > 207 dB PK	(N) Moderate (I) Low (F) Low	(N) Moderate (I) Low (F) Low	Pile driving: (N) Moderate (I, F) Low Seismic: (N, I, F) Low	(N) Moderate (I, F) Low

Peak sound pressure level dB re 1 µPa; SEL$_{24\text{h}}$ dB re 1µPa^{2}·s.
All criteria are presented as sound pressure even for fish without swim bladders since no data for particle motion exist.
Relative risk (high, moderate, low) is given for animals at three distances from the source defined in relative terms as near (N), intermediate (I), and far (F).

2.2.1.1. Turtles

There is a paucity of data regarding responses of turtles to acoustic exposure, and no studies of hearing loss due to exposure to loud sounds. McCauley et al. (2000a) observed the behavioural response of caged turtles—green (*Chelonia mydas*) and loggerhead (*Caretta caretta*)—to an approaching seismic airgun. For received levels above 166 dB re 1 µPa (SPL), the turtles increased their swimming activity and above 175 dB re 1 µPa they began to behave erratically, which was interpreted as an agitated state. The 166 dB re 1 µPa level has been used as the threshold level for a behavioural disturbance response by NMFS and applied in the Arctic Programmatic Environment Impact Statement (PEIS) (NSF 2011). At that time, and in the absence of any data from which to determine the sound levels that could injure an animal, TTS or PTS onset were considered possible at an SPL of 180 dB re 1 µPa (NSF 2011). Some additional data suggest that behavioural responses occur closer to an SPL of 175 dB re 1 µPa, and TTS or PTS at even higher levels (Moein et al. 1995), but the received levels were unknown and the NSF (2011) PEIS maintained the earlier NMFS criteria levels of 180 and 166 dB re 1 µPa (SPL) for injury and behavioural response, respectively. Popper et al. (2014) suggested injury to turtles could occur for sound exposures above 207 dB re 1 µPa (PK) or above 210 dB re 1 µPa^2·s (SEL$_{24h}$). Sound levels defined by Popper et al. (2014) show that animals are very likely to exhibit a behavioural response when they are near an airgun (tens of metres), a moderate response if they encounter the source at intermediate ranges (hundreds of metres), and a low response if they are far (thousands of meters) from the airgun.

Finneran et al. (2017) presented revised thresholds for turtle injury (PTS) and TTS, considering both PK and frequency weighted SEL, which have been applied in this study, along with the NMFS criterion for behavioural response (SPL of 166 dB re 1 µPa), and a criterion for behavioural disturbance (SPL of 175 dB re 1 µPa) (Moein et al. 1995, McCauley et al. 2000a, 2000b) (Table 13).

Table 13. Acoustic effects of impulsive noise on turtles: Unweighted SPL, SEL$_{24h}$, and PK thresholds

NSF (2011)	**Moein et al. (1995), McCauley et al. (2000a), (2000b)**	**Finneran et al. (2017)**			
Behaviour		**PTS onset thresholds* (received level)**		**TTS onset thresholds* (received level)**	
SPL (L_p; dB re 1 µPa)		Weighted SEL$_{24h}$ ($L_{E,24h}$; dB re 1 µPa^2·s)	PK (L_{pk}; dB re 1 µPa)	Weighted SEL$_{24h}$ ($L_{E,24h}$; dB re 1 µPa^2·s)	PK (L_{pk}; dB re 1 µPa)
160	175	204	232	189	226

* Dual metric acoustic thresholds for impulsive sounds: Use whichever results in the largest isopleth for calculating PTS onset. If a non-impulsive sound has the potential of exceeding the peak sound pressure level thresholds associated with impulsive sounds, these thresholds should also be considered.

L_p denotes sound pressure level period and has a reference value of 1 µPa.

$L_{pk,flat}$ denotes peak sound pressure is flat weighted or unweighted and has a reference value of 1 µPa.

L_E denotes cumulative sound exposure over a 24 h period and has a reference value of 1 µPa^{2}s.

2.2.2. Continuous noise

Table 14 lists the relevant effects thresholds from Popper et al. (2014) for shipping and continuous noise. Some evidence suggests that fish sensitive to acoustic pressure show a recoverable loss in hearing sensitivity, or injury when exposed to high levels of noise (Scholik and Yan 2002, Amoser and Ladich 2003, Smith et al. 2006); this is reflected in the SPL thresholds for fish with a swim bladder involved in hearing.

Finneran et al. (2017) presented revised thresholds for turtle injury, considering frequency weighted SEL, which have been applied in this study for vessels (Table 15).

Table 14. Criteria for vessel noise exposure for fish, adapted from Popper et al. (2014).

Type of animal	**Mortality and Potential mortal injury**	**Impairment**			**Behaviour**
		Recoverable injury	TTS	Masking	
Fish: No swim bladder (particle motion detection)	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) Moderate (I) Low (F) Low	(N) High (I) High (F) Moderate	(N) Moderate (I) Moderate (F) Low
Fish: Swim bladder not involved in hearing (particle motion detection)	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) Moderate (I) Low (F) Low	(N) High (I) High (F) Moderate	(N) Moderate (I) Moderate (F) Low
Fish: Swim bladder involved in hearing (primarily pressure detection)	(N) Low (I) Low (F) Low	170 dB SPL for 48 h	158 dB SPL for 12 h	(N) High (I) High (F) High	(N) High (I) Moderate (F) Low
Turtles	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) Moderate (I) Low (F) Low	(N) High (I) High (F) Moderate	(N) High (I) Moderate (F) Low
Fish eggs and fish larvae	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) High (I) Moderate (F) Low	(N) Moderate (I) Moderate (F) Low

Sound pressure level dB re 1 µPa.
Relative risk (high, moderate, low) is given for animals at three distances from the source defined in relative terms as near (N), intermediate (I), and far (F).

Table 15. Acoustic effects of continuous noise on turtles, weighted SEL_{24h}, Finneran et al. (2017).

PTS onset thresholds* (received level)	**TTS onset thresholds* (received level)**
Weighted SEL_{24h} ($L_{E,24h}$; dB re 1 µPa2·s)	Weighted SEL_{24h} ($L_{E,24h}$; dB re 1 µPa2·s)
204	189

L_E denotes cumulative sound exposure over a 24 h period and has a reference value of 1 µPa^{2}s.

3. Methods

The operations considered in this study will take place at the Torosa and Brecknock fields, respectively, at depths 391–567 m (Appendix F.3.1). For the sites within the Torosa field, sound propagation is partially blocked in some directions by the reefs, due to a sharp decrease in water depth. Activities could take place at any time in the year. For this reason, the most conservative water sound speed profile (i.e., the profile leading to the longest acoustic propagation) was selected for modelling (Appendix F.3.2). Directly under the modelled sites, the seabed consists of silt, typical of the continental slope (Appendix F.3.3). When approaching the reefs, however, the seabed transitions from silt to sand/gravel, and then to limestone at the reefs.

This section described the methods used to characterise acoustic sources (driven piles, vessels and VSP), as well as the acoustic propagation models and frequency ranges considered for estimation of acoustic fields.

3.1. Pile driving

To predict the acoustic field around the pile driving at frequencies from 10 Hz to 1 kHz, JASCO's Pile Driving Source Model (PDSM; Appendix B) was used in conjunction with JASCO's Full Waveform Range-dependent Acoustic Model (FWRAM, Appendix E.2). In addition, a model-based extrapolation was applied to these results to extend the modelling range up to 25 kHz. Three different seafloor penetration depths were accounted for.

The SEL results for the entire pile were determined through the accumulation of energy across the entire pile driving operation, accounting for the sound fields from each strike and how the sound field changes as the pile penetrates further into the seafloor.

3.2. Vertical Seismic Profiling

The pressure signature of the individual airguns and the composite 1/3-octave-band point-source equivalent directional levels (i.e., source levels) of the 750 in^3 VSP source operated at 6 m were modelled with JASCO's Airgun Array Source Model (AASM, Appendix C.1).

Three sound propagation models were used to predict the acoustic field around the VSP source:

- Combined range-dependent parabolic equation and Gaussian beam acoustic ray-trace model (MONM-BELLHOP, 10 Hz to 25 kHz, Appendix E.3).
- Full Waveform Range-dependent Acoustic Model (FWRAM, 0.5 Hz to 1024 Hz, Appendix E.2).
- Wavenumber integration model (VSTACK, 10 Hz to 2048 Hz, Appendix E.4).

The models were used in combination to characterise the acoustic fields at short and long ranges in terms of SEL, SPL, PK, and PK-PK. Appendix E details each model. MONM was used to calculate SEL of a 360° area around each source location. VSTACK was used to calculate close range PK, PK-PK, and SEL along transects at the seafloor from the broadside direction of the seismic source. For the VSP source, FWRAM was used to calculate PK in the entire water column along four selected transects, and to obtain a conversion factor to estimate SPL from the MONM-BELLHOP SEL results.

3.3. Vessel noise (MODU, OSV, and FPSO)

JASCO's Marine Operations Noise Model (MONM-BELLHOP Appendix E.3) was used to predict the acoustic field at frequencies of 10 Hz to 63 kHz for all vessels.

For all vessels, the sound exposure level (SEL) modelling results were converted to SPL by the duration of the measurement, which is appropriate for a continuous noise source. As SEL was assessed over 24 h, the conversion to SPL was obtained by reducing the levels by $10*\log_{10}(T)$, where T is 86,400 (the number of seconds in 24 h).

3.4. Pile Driving Modelling

3.4.1. Per-strike Modelling

For impact pile driving sounds, time-domain representations of the pressure waves generated in the water are required for calculating sound pressure level (SPL), sound exposure level (SEL), and peak sound pressure level (PK). Appendix A.1 describes these sound level metrics. The following steps comprise the general approach applied in this study to model sounds from impact pile driving activities:

1. Piles driven into the sediment by impact driving are characterised as sound-radiating sources. This characterisation strongly depends on the rate and extent of pile penetration, pile dimensions, and pile driving equipment.
2. The theory of underwater sound propagation is applied to predict how sound propagates from the pile into the water column as a function of range, depth, and azimuthal direction. Propagation depends on several conditions including the frequency content of the sound, the bathymetry, the sound speed in the water column, and sediment geoacoustics (Appendix F.3 describes environmental properties such as bathymetry, sound speed profile, and geoacoustics).
3. The propagated sound field is used to compute received levels over a grid of simulated receivers, which distances to criteria thresholds and maps of ensonified areas are generated from.

To model sounds resulting from impact pile driving of cylindrical pipes, PDSM (Appendix B), a physical model of pile vibration and near-field sound radiation (MacGillivray 2014), is used in conjunction with the GRLWEAP 2010 wave equation model (GRLWEAP, Pile Dynamics 2010). JASCO modelled the IHC S-600 and IHC S-1200 impact hammers. Figure 2 shows the force at the top of the pile that is produced by GRLWEAP.

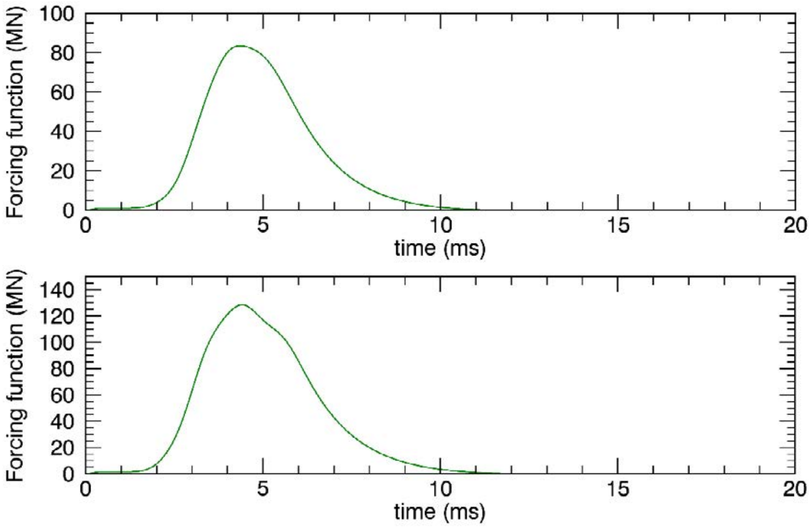

Figure 2. Force (in meganewtons) at the top of the pile corresponding to impact pile driving of a 5.5 m diameter pile, computed using the GRLWEAP 2010 wave equation model for the (top) IHC S-600 and (bottom) IHC S-1200 impact hammers.

The forcing functions (Figure 2) are used by the PDSM to obtain equivalent pile driving signatures for a vertical array of discrete point sources (Appendix B). These represent the pile as an acoustic source and account for parameters (pile type, material, size, and length), the pile driving equipment, and approximate pile penetration rate. The amplitude and phase of the point sources along the pile are computed so they collectively mimic the time-frequency characteristics of the acoustic wave at the pile wall that results from a hammer strike at the top of the pile. This approach accurately estimates spectral levels within the band 10–1000 Hz where most of the energy from impact pile driving is concentrated.

Time-domain Full Waveform Range-dependent model (FWRAM; Appendix E.2) calculates sound propagation from physically distributed impulsive sources and is valid at all distances. In the present study, received sound levels were calculated using FWRAM along transects at 28 azimuths out to 80 km from the source every 10 m, generating a total modelling area of 20000 km^2. Modelling was conducted in non-uniform azimuth increments, with a higher concentration of transects in the direction of bathymetric features of interests, such as reefs around the pile. Grids of received sound levels with 3° azimuth resolution were constructed. To this end, each 3° resolution transect was assigned the received levels corresponding to the modelled transect with the most similar bathymetry.

Source band levels at 1000 Hz were extrapolated up to 25 kHz using a 20 dB/decade decay rate to match acoustic measurements of impact pile driving of similarly sized piles (Illingworth & Rodkin 2007, Matuschek and Betke 2009).

Receiver depths are chosen to span the entire water column over the modelled areas, from 1 to 2600 m, with step size that increase with depth. To produce maps of received sound level distributions and to calculate distances to specified sound level thresholds, the maximum-over-depth level is calculated at each modelled easting and northing position within the considered region. The radial grids of maximum-over-depth levels are then resampled (by linear triangulation) to produce a regular Cartesian grid. The contours and threshold ranges are calculated from these flat Cartesian projections of the modelled acoustic fields (Appendix F.1).

3.4.2. Accumulated SEL Modelling

The modelling approach outlined in Sections 3.4.1 provides per-strike SEL for three stages of pile driving (i.e., three penetration depths). Several noise effect criteria, however, depend on accumulated SEL over many strikes (Section 2). For the purposes of modelling, one pile will be driven per day; therefore, while the corresponding sound level is denoted SEL_{24h}, the period of accumulation is determined based upon the estimated time for driving a single complete pile. Therefore, the accumulated SEL over a single pile, or the SEL_{24h}, depends on the total number of strikes.

Total driving time was estimated assuming continuous piling at a rate of approximately 0.67 strikes/second (40 strikes/minute) and 0.52 strikes/second (31 strikes/minute) for the IHC S-600 and the IHC S-1200 hammers, respectively. The number of strikes required for the driving of the pile were determined based upon a drivability assessment provided by Woodside for these two hammers operating at 95% efficiency. A summary of the total number of strikes per penetration depth and over the entire pile is provided in Tables 16 and 17.

Table 16. *Torosa*: total number of strikes and driving time. Strikes were broken down into stages corresponding to the three modelled penetrations.

Hammer	Modelled penetration (m)	Penetration range for accumulated SEL (m)	Number of strikes	Penetration rate (mm/strike)	Total number of strikes	Time for full penetration (min)
IHC S-600	17	10–24	595	19.9	3141	78.5
	31	24–38	1026	13.4		
	45	38–51.5	1520	8.0		
IHC S-1200	17	10–24	256	38.5	1412	45.5
	31	24–38	488	28.4		
	45	38–51.5	668	18.3		

Table 17. *Brecknock*: total number of strikes and driving time. Strikes were broken down into stages corresponding to the three modelled penetrations.

Hammer	Modelled penetration (m)	Penetration range for accumulated SEL (m)	Number of strikes	Penetration rate (mm/strike)	Total number of strikes	Time for full penetration (min)
IHC S-600	17	10–24	582	19.7	3203	80.0
	31	24–38	1043	12.7		
	45	38–51.5	1578	7.49

	31	24–38	497	27.0		
	45	38–51.5	709	16.9		

3.5. VSP Modelling

3.5.1. Per-pulse Modelling

To assess sound levels with MONM-BELLHOP, the sound field modelling calculated propagation losses up to distances at least 150 km from the source, with a horizontal separation of 20 m between receiver points along the modelled radials. The sound fields were modelled with a horizontal angular resolution of $\Delta\theta$ = 2.5° for a total of N = 144 radial planes. Receiver depths were chosen to span the entire water column over the modelled areas, from 2 m to a maximum of 3100 m, with step sizes that increased with depth. To supplement the MONM results, high-frequency results for propagation loss were modelled using Bellhop for frequencies from 2 to 25 kHz. The MONM and Bellhop results were combined to produce results for the full frequency range of interest.

FWRAM was run to 80 km, but along only four radials (fore and aft endfire, and port and starboard broadside) for computational efficiency, from 5 to 1024 Hz in 1 Hz steps. This was done to compute SEL-to-SPL conversions (Appendix F.2) but also to quantify water column PK and PK-PK. The horizontal range step is dependent on frequency and ranges from 50 m at lower frequencies to 10 m above 800 Hz.

The maximum modelled range for VSTACK was 1500 m and a variable receiver range increment that increased away from the source was used. The increment increased from 5 to 50 m. Received levels were computed for receivers at seafloor

3.5.2. Multiple-pulse Modelling

The VSP operation was assessed in this report by considering several potential scenarios for a maximum number of pulses per 24 h. The SEL was assessed over 24 h by adjusting the single-pulse SEL by $10 \cdot \log_{10}(N)$, where the total number of pulses N was 1, 5, 10, 15, 25, 50, 100, and 150 at each location (Torosa TRD Well and Brecknock).

3.6. Acoustic Source Parameters for MODU, OSV, and FPSO

3.6.1. Mobile Offshore Drilling Unit (MODU)

The estimates of the MODU, or semi-submersible platform, acoustic source levels and sound spectrum were based on the *Seadrill West Sirius* (Figure 3). *Seadrill West Sirius* is reportedly equipped with eight Rolls-Royce UUC 355 thrusters.

The parameters for the UUC 355 thruster are:

- 3.5 m propeller diameter,
- 177 rpm nominal propeller speed, and
- 3800 kW maximum continuous power input.

For modelling, all eight thrusters were assumed to operate at 50%. The vertical position of the thrusters was 18 m below the sea surface (draft of the rig during drilling operations). Figure 4 shows the thruster locations.

Figure 3. *Seadrill West Sirius* semi-submersible platform.

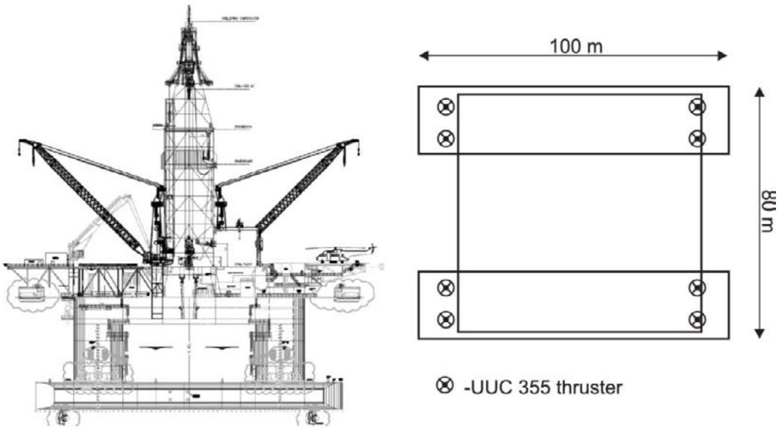

Figure 4. *Seadrill West Sirius* dimensions and thruster locations (circles).

The source levels and the sound spectrum for vessel thrusters were estimated based on the thruster specifications (diameter, revolutions-per-minute (rpm)) and the method described in Section 3.6. It is expected that the MODU at Torosa and Brecknock will operate under dynamic positioning representative of typical operational loads during moderate weather conditions. Measurements and modelling of thruster noise from the Technip *Deep Orient* (Quijano and McPherson 2018) suggest that the broadband source levels decrease when the vessel operates under mild environmental conditions compared to rough weather. Based on the monopole source levels calculated for the Technip *Deep Orient* during the measurement study, we decreased the MODU thruster levels by 5.75 dB, to account for the typical scenario with moderate environmental conditions. Figure 8 shows the MODU source levels used for this modelling, compared to measurements obtained from a similar MODU and a drillship (West Aquarius and Stena IceMAX, see Martin et al. (2019)). For additional reference, MODU thruster source levels corresponding to full capacity (i.e., rough weather) from Zykov (2016) are shown. Note that the MODU source levels correspond to the noise generated by eight thrusters operating simultaneously, while the modelling considers each thruster as an individual source.

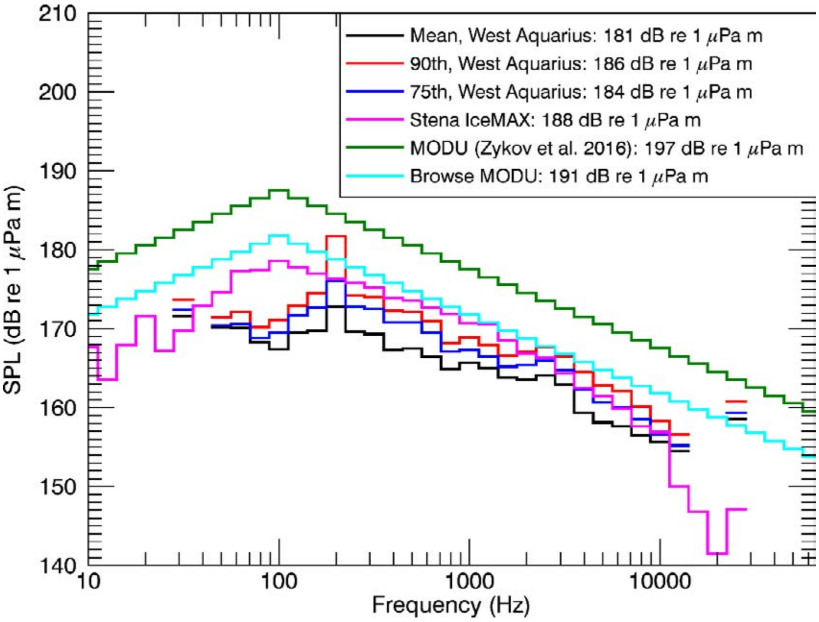

Figure 5. *MODU*: One-third-octave-band source levels. The levels assume operation of the MODU at 50% load, and account for the presence of eight thrusters. For comparison, source levels obtained from measurements of the noise generated by the West Aquarius and the Stena IceMAX (Martin et al. 2019) are provided. In addition, predicted source levels for the same MODU considered in this study under heavy operating conditions (Zykov 2016) are presented.

3.6.2. Offshore Support Vessel (OSV)

The estimates of acoustic source levels and sound spectrum for the support vessel were based on the *MMA Inscription* platform supply vessel, referred to in this report as an Offshore Support Vessel (OSV) (Figure 6). The *MMA Inscription*, of length 87.08 m, breadth of 18.8 m and maximum draft of 5.9 is equipped with two bow (main) azimuthal thrusters, one stern retractable azimuthal thruster, and one bow thruster. Since parameters such as propeller size or thruster vertical position were not available, thrusters were modelled at depth 5.9 m, equal to the draft. The bow thrusters are 2000 kW maximum continuous power input each, while the bow thruster is 910 kW maximum continuous power input. For this modelling, the stern retractable thruster was not included. Figure 7 shows the thruster locations.

Source levels for the *MMA Inscription* were obtained based on those of the Damen platform supply vessel 3300CD (length 80.08 m, breadth of 16.8 m and maximum draft of 6.9), which was used in previous studies (Zykov 2016). For the Damen 3300CD, the bow (main) thrusters are 2000 kW maximum continuous power input each, while smaller bow thrusters are 735 kW maximum continuous power input. Unlike Zykov (2016), in which thrusters were assumed to operate at full capacity, modelling in this study was conducted assuming a 25% capacity. For this reason, thrusters levels from Zykov (2016) were offset by $10*\log_{10}(0.25)$ for the main thrusters, and by $10*\log_{10}(0.25)+10*\log_{10}(910/735)$ for the bow thruster. The source levels for individual thrusters are shown in Figure 8.

Figure 6. Image of the *MMA Inscription* (MMA Offshore 2019).

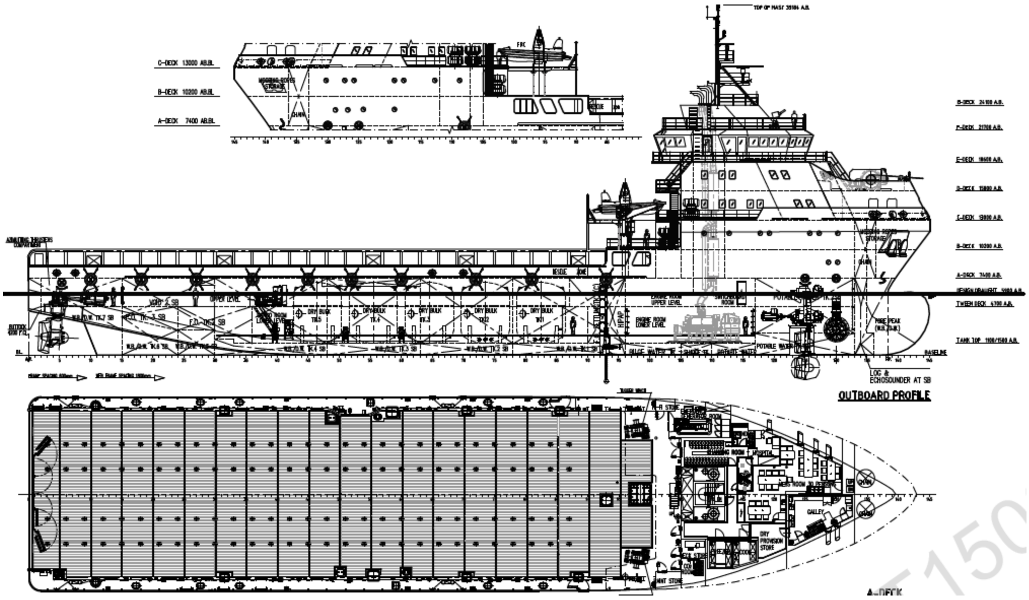

Figure 7. Nominal dimensions and thruster locations (circles) of the *MMA Inscription* (MMA Offshore 2019).

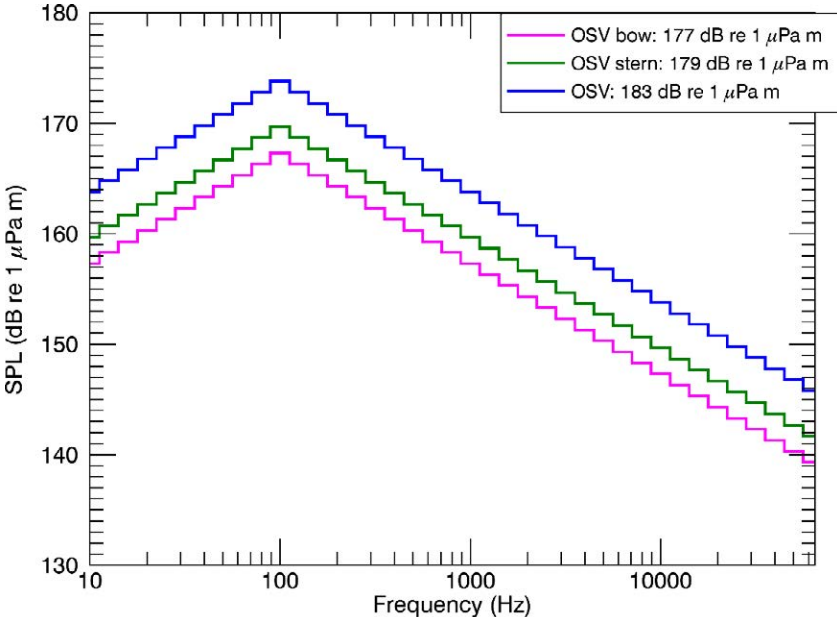

Figure 8. *OSV*: One-third-octave-band source levels of individual bow and stern thrusters. The OSV curve include the two individual stern thrusters and the bow thruster.

3.6.3. Floating Production, Storage, and Offloading (FPSO) facility

The proposed FPSO facility is a dynamically positioned production vessel approximately 370 m long and 67 m wide with a draft of 16 m. While in DP mode, it operates on two stern thrusters positioned laterally on the keel at the stern of the ship, right next to each other. Each thruster is rated at 5 MW. The vessel type and specifications are similar to the Woodside FPSO facilities *Ngujima Yin* and *Nganhurra* (with the important exception of the two thrusters rated at 2.94 MW each), from which JASCO gathered measurements in 2010 (Erbe et al. 2013). The measured spectra for these two vessels were averaged and used as a surrogate for the FPSO facility. Because the *Ngujima Yin* and *Nganhurra* were moored, they were not offloading, and the weather was calm, they were not under DP when they were measured. These averaged source levels were used in this report to model FPSO operations without DP.

To model operations that include DP, sound levels of thruster noise were added to the (non-DP) source spectrum. Sound levels for DP thruster noise were based on measurements of the dive support vessel *DSV Fu Lai* (MacGillivray 2006). The composite source spectrum (i.e., non-DP and DP components) was adjusted for the difference in total operational power level between the DSV *Fu Lai* and the FPSO facility using the following equation:

$$SL = SL_{FuLai} + 10\log\left(HP/HP_{ref}\right)\ , \qquad (1))$$

where HP_{ref} is the level of reference power. The source spectrum was additionally modified to consider the operational level of the *Fu Lai* thrusters relative to the desired operational level for the FPSO facility. Given that DP does not require full thrust, the *Fu Lai*'s thrusters only operated at between 20% and 30% of capacity when measured. To achieve a conservative estimate, FPSO facility thrusters were modelled at 50% power capacity. In addition to the adjustment in Eq.1, an offset of 10*$\log_{10}$(5/2.94) was applied to the composite source spectrum, to account for the difference in thruster power between the *Ngujima Yin* and *Nganhurra*, and the FPSO considered in this study.

The acoustic modelling source depth was determined by assuming the bottoms of the thrusters were at the draft of the vessel, but the noise from cavitation is known (Wright and Cybulski 1983) to be centralised at approximately three quarters of the propeller's height.

In the absence of information about the propeller diameters and vertical position, modelling was conducted assuming point sources at 16 m to be conservative. For modelling, it was assumed that both thrusters operated at the middle (50%) of their constant power range, at a constant speed. The thrusters are located at the stern section of the vessel; for modelling purposes, however, the source location was placed in the planar centre of the vessel to approximate a point source. Because this assessment is focused on the far-field noise from all sources on the vessel (including not just thruster noise, but also noise from ancillary equipment for power generation, etc.) the point source approximation is suitable. Figure 9 shows 1/3-octave-band source levels for the FPSO facility (with and without DP).

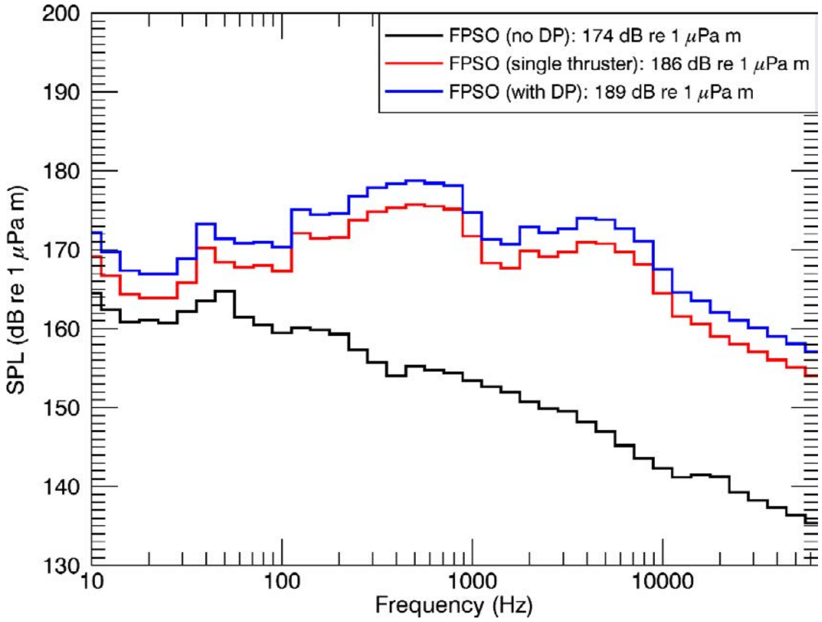

Figure 9. *FPSO*: One-third-octave-bands of modelled FPSO facility without DP, with DP (single thruster), and with DP (two thrusters).

3.6.4. FPSO Offtake

Offtake operations considered in this study consist of an FPSO on DP, a condensate tanker, and an OSV (Figure 10). The modelling scenario includes the tanker (which is considered noiseless in this study) is between the FPSO and the OSV, with the bow 80 m from the stern of the FPSO, and the OSV 700 m from the stern of the FPSO, pointing away from the FPSO. The offtake scenarios were modelled by adding the contributions from the maximum-over-depth grids computed for the individual vessels detailed in Sections 3.6.2 and 3.6.3.

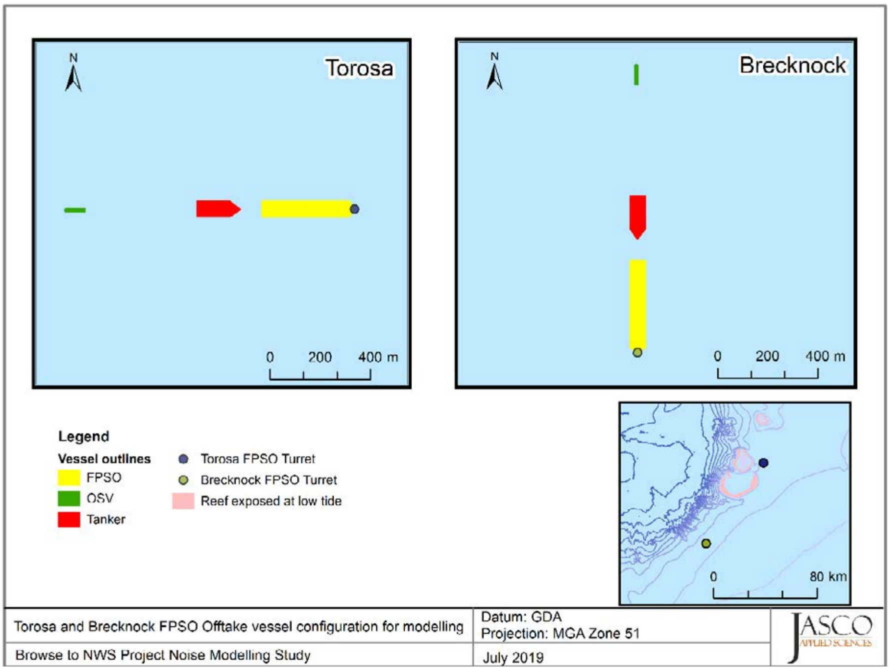

Figure 10. Torosa and Brecknock FPSO Offtake vessel configuration for modelling, showing FPSO, tanker, and OSV.

3.7. Animal Movement and Exposure Modelling

The JASCO Animal Simulation Model Including Noise Exposure (JASMINE) was used to predict the exposure of animats (virtual marine mammals) to sound arising from the pile driving. Sound exposure models like JASMINE integrate the predicted sound field with biologically meaningful movement rules for each marine mammal species (here: pygmy blue whales and green turtles) that result in an exposure history for each animat in the model. In JASMINE, the sound received by the animats is determined by the proposed pile driving activity pattern. As shown in Figure 11, animats are programmed to behave like the marine animals that may be present in the area. The parameters used for forecasting realistic behaviours (e.g., diving and foraging depth, swim speed, surface times) are determined and interpreted from marine mammal studies (e.g., tagging studies) where available, or reasonably extrapolated from related or comparable species. An individual animat's sound exposure levels are summed over a specified duration, such as 24 h or the entire simulation, to determine its total received energy, and then compared to the threshold criteria (for detailed information on JASMINE see Appendix G).

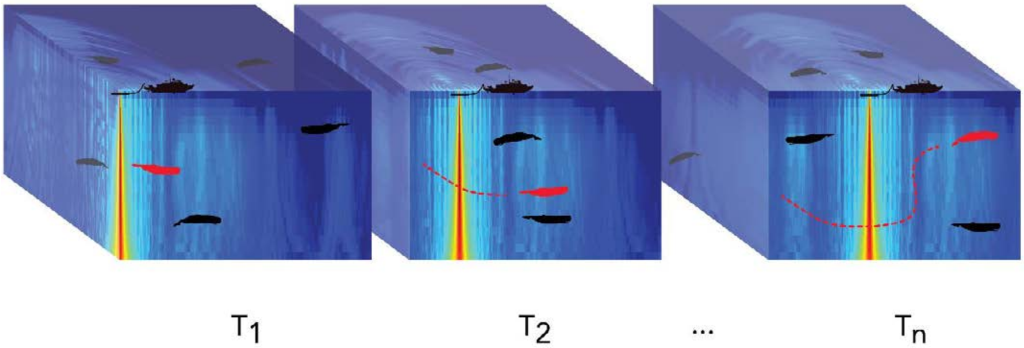

Figure 11. Cartoon of animats in a moving sound field. Example animat (red) shown moving with each time step (T_x). The acoustic exposure of each animat is determined by where it is in the sound field, and its exposure history is accumulated as the simulation steps through time.

3.7.1. Methodology

The exposure criteria for impulsive sounds (described in Section 2) were used to determine the number of animats exceeding thresholds. Model simulations were run with animat densities of 15 animats/km^2 for pygmy blue whales and 15 animats/km^2 green turtles to generate a statistically reliable probability density function for each species. To evaluate potential injury (PTS), TTS, and behavioural disturbance, exposure results were summed over the driving of a single pile (Table 16), which represents the exposure over 24 h, represented by animats described in Appendix G.

Specific areas of interest are defined for both pygmy blue whales and green turtles depending on behavioural mode (e.g., migrating, foraging, inter-nesting). Figures 12 and 14 show maps of the modified Biologically Important Areas (BIAs) for migrating and inter-nesting green turtles, while Figures 13 and 15 show the Department of Environment and Energy (DoEE) BIAs for migrating and foraging pygmy blue whales. Both of these maps also show the extents of the modelling and animat simulation area. For the final calculations, BIA areas are clipped to the extents of the simulation. To account for the difference between the animat simulation area and the BIAs, the final exposure estimates are scaled by the ratio of the clipped BIA relative to the simulation area.

The modified BIA for green turtle inter-nesting area is restricted to the 50 m contour around North and South Scott Reef, and connects between the two Reefs (Figure 12), this area was defined based upon the best available science (turtle tagging data (Guinea 2011) and external advice), and has been applied in this study instead of the DoEE defined inter-nesting BIA boundary around Scott Reef. While the simulations assume the inter-nesting green turtles are evenly distributed within the defined area of interest, the majority are concentrated on or next to Sandy Islet (Guinea 2009). The migratory area has been defined based upon tagged turtles (Guinea 2011) and the area prescribed is based upon the distance a turtle would transit within 24 h.

The animal simulation model requires detailed behavioural information on how the modelled species moves in the water column. This is detailed in Sections 3.7.2 and 3.7.3 for pygmy blue whales and green turtles, respectively.

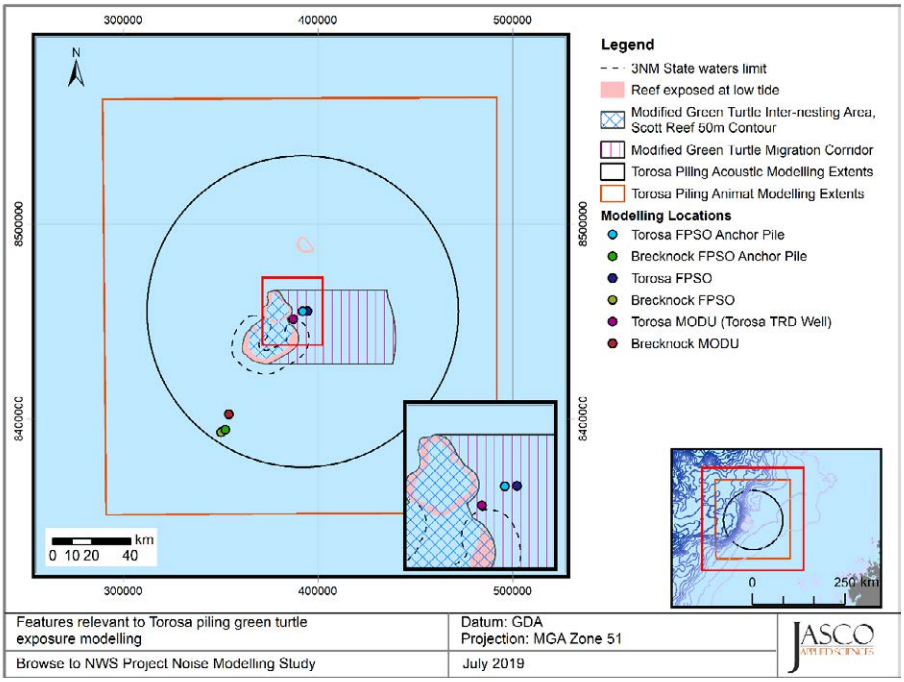

Figure 12. *Torosa:* Map of green turtle exposure modelling features, including modified BIAs for inter-nesting and migrating green turtles, along with extents for acoustic propagation modelling and animat modelling.

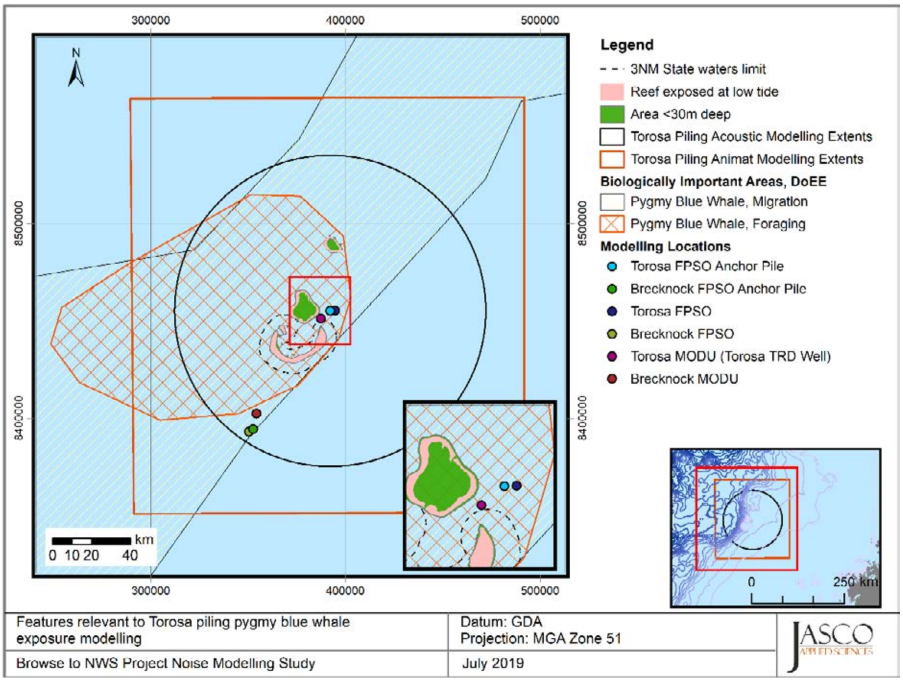

Figure 13. *Torosa*: Map of pygmy blue whale exposure modelling features, including BIAs for foraging and migrating pygmy blue whales, along with extents for acoustic propagation modelling and animat modelling.

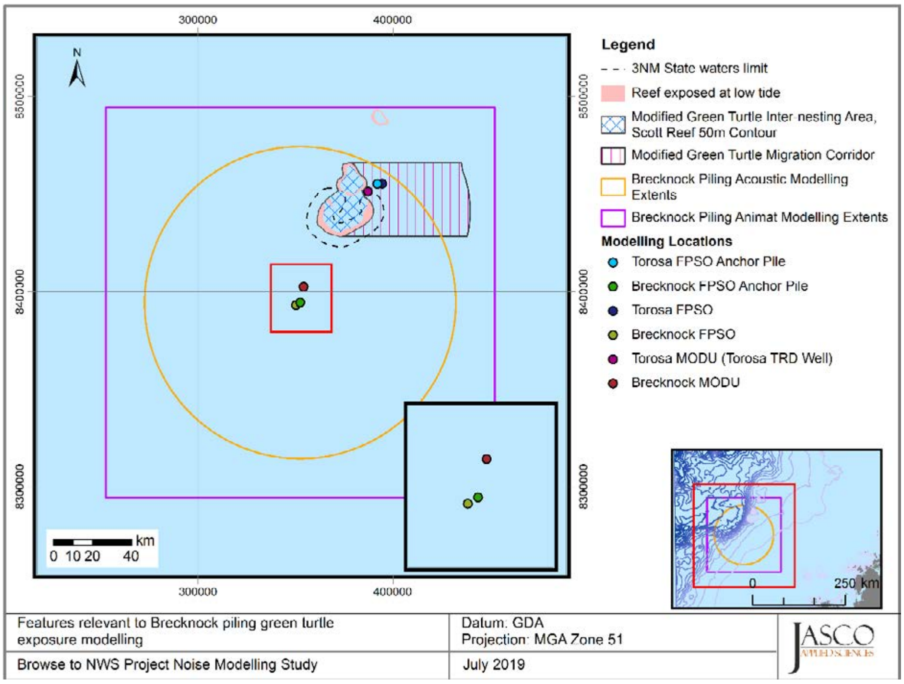

Figure 14. *Brecknock:* Map of green turtle exposure modelling features, including modified BIAs for inter-nesting and migrating green turtles, along with extents for acoustic propagation modelling and animat modelling.

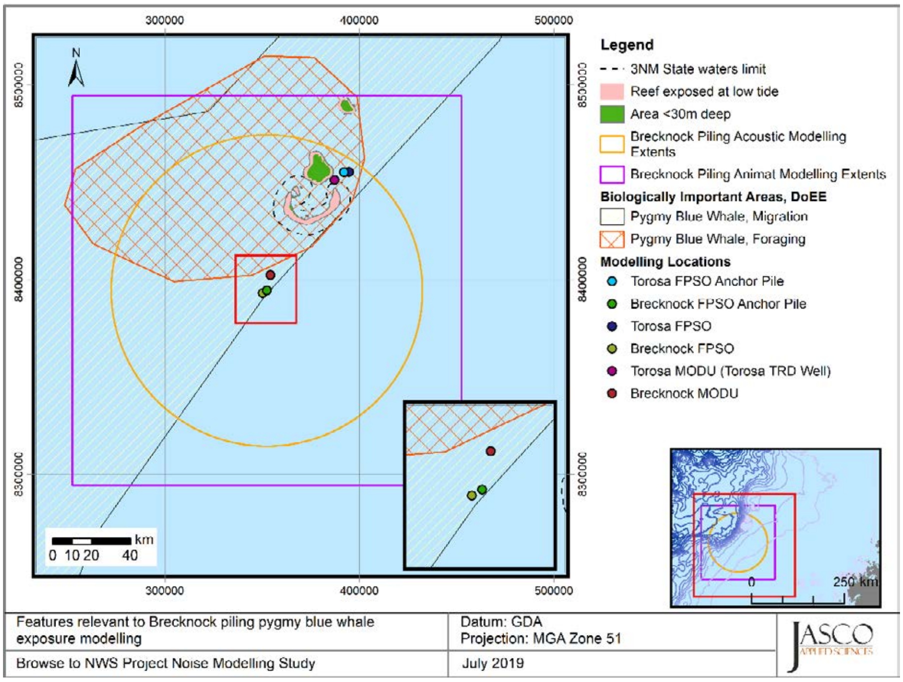

Figure 15. *Brecknock*: Map of pygmy blue whale exposure modelling features, including BIAs for foraging and migrating pygmy blue whales, along with extents for acoustic propagation modelling and animat modelling.

In the case of the inter-nesting green turtles, the pile location is approximately 7.9 km away from the closest point of the BIA. To ensure that no animats are impacted outside the relevant BIA, exposures occurring at ranges smaller than the minimum distance between the pile and the BIA were not included in the final count. This effectively reduces the simulation area by πr^2, where r = 7.9 km. Therefore, the final area-based scaling S_A is

$$S_A = \frac{BIA_{clipped}}{(A_{full} - \pi r^2)}, \quad (2)$$

where $BIA_{clipped}$ is the BIA clipped to the full animat simulation area A_{full}. Pygmy blue whales are not expected in water depths less than 30 m, so the clipped BIA is reduced by the area within the 30m depth contour (Figure 13). A summary of the BIA areas and the various inputs to exposure scaling for each of the animat modelling scenarios can be found in Table 18.

The total number of animats exposed above behaviour, TTS and PTS threshold criteria were scaled using the seeded density D_S and the real-world density D_R, where available. The scaling factor S_D is therefore

$$S_D = \frac{D_R}{D_S}. \quad (3)$$

The total number of real-world animals N_{exp} expected to be impacted above threshold is computed from the raw animat exposures and the scaling factors as

$$N_{exp} = S_A S_D. \quad (4)$$

The distribution of ranges of exposed animats was used to estimate the 95th percentile ranges at which the animats were exposed above threshold. Within the 95th percentile range, there are generally some proportion of animats that did not exceed threshold criteria.

During pile driving operations, exclusion zones of 500 m for turtles and 2000 m for pygmy blue whales will be in place. These will be managed using mitigation protocols determined by Woodside, and through their implementation, exposures to turtles and pygmy blue whales near the pile where sound levels are highest will be limited. The overall effect of implementing these exclusion zones was estimated using animat modelling by removing any exposures occurring within the exclusion zone.

3.7.2. Pygmy blue whales

3.7.2.1. Animal behaviour

Two behavioural profiles were considered for pygmy blue whales, foraging and migration. The research summarised in this section was used to inform the species behavioural definition (Appendix G.2). Detailed, fine-scale diving behaviour of a migrating pygmy blue whale was derived from Owen et al. (2016) who equipped an individual with a multi-sensor tag off the west coast of Australia. The study identified areas of high residence using the horizontal movement data; the analysis of the dive data showed that the depth of migratory dives was highly consistent over time and unrelated to local bathymetry. Blue whales (*Balaenoptera musculus*) are known to primarily migrate and feed in the first few hundred metres of the water column (Croll et al. 2001, Goldbogen et al. 2011), with the deepest dive being reported from a pygmy blue whale being 506 m (Owen et al. 2016). Dives were identified as migratory, feeding, or exploratory behaviour. The mean depth of migratory dives (82% of all dives) was 14 m ± 4 m, and the whale spent 94% of observed time and completed 99% of observed migratory dives at water depths of less than 24 m. A total of 21 feeding dives were identified during the duration of the tag deployment (one week) with a mean maximum depth of 129 ± 183 m (range 13–505 m). The mean maximum depth of exploratory dives (107 ± 81 m, range 23–320 m) was similar to the mean maximum depth of feeding dives (129 m) and did not appear to be related to seafloor depth.

The behaviour of pygmy blue whales was modelled without migration bias, i.e. the animats were resident in the animat modelling area over the entire modelling period. In reality, pygmy blue whales can be expected to transit through the area in less than half a day (based on McCauley and Jenner 2010); accordingly, the approach used is conservative as it results in higher exposure levels and higher number of animals exposed to levels exceeding the criteria thresholds.

The two migratory behaviours (migratory dives and exploratory dives) were modelled at an even probability of occurrence (i.e. probability for transitioning from one behaviour to another was 0.5 for both) while dive data published by Owen et al. (2016) suggest a higher likelihood for migratory dives to occur. This approach was chosen in the absence of quantitative information on the true proportion between the two dive behaviours. It represents another conservative measure, given the assumption that for sub-sea piling, exposure levels are higher at depth as compared to the surface.

3.7.2.2. Density estimates

The entire region off the northwestern coast of Australia is a poorly studied with regard to the abundance and distribution of pygmy blue whales. As described in McCauley et al. (2018), there are two estimates for the Eastern Indian Ocean pygmy blue whale population size along the coastline of Western Australia (WA), the first calculated in 2004 by McCauley and Jenner (2010) at 662–1559 southbound animals, using passive acoustics, and the second calculated over 2002–2006 by Jenner et al. (2008) of 712–1754. Neither of these estimates account for whales further west in the Indian Ocean, and there is evidence that along the WA coast north of latitude ~ 19° S that the migratory pathway spreads out (Gavrilov et al. 2018), with not all animals following the Australian coastline; therefore it is unknown what proportion of the Eastern Indian Ocean pygmy blue whale population either follow the coast or travel further west (McCauley et al. 2018).

However, while near the coast, the observations in McCauley and Jenner (2010) suggested most pygmy blue whales pass along the shelf edge out to water depths of 1000 m but centred near the 500 m depth contour. The boundaries of the DoEE pygmy blue whale migration BIA are designed to reflect this general migratory pattern. The areas considered in this simulation were greater than the acoustic modelling region to provide a buffer zone around the sound fields to account for the possibility of animats moving into and out of the modelled sound fields.

McCauley et al. (2018) provides an estimate for the annual growth rate of pygmy blue whales at Portland (Victoria) of 4.3% per year. However, as pointed out by the authors, this growth rate applies only to the proportion of the population using the south eastern Australian coast, and as such may not reflect the growth rate of the full population. However, in the absence of other population growth estimates, this estimate has been applied as a conservative estimate to the proportion of the population also using the WA coast, in particular the migratory BIA.

Considering an annual growth rate of 4.3%, the two population estimates provided in McCauley and Jenner (2010) and Jenner et al. (2008) have been considered to determine the potential current population, and thus the possible percentage increase since the estimate was derived, as shown in Table 19.

Table 19. Population growth estimates based on 4.3% per annum.

Source	Year	Minimum estimate	Maximum estimate	Percentage increase
Based on McCauley and Jenner (2010)	2004, Estimated	662	1559	
	2019, Extrapolated	1245	2932	188%
Based on Jenner et al. (2008)	2002-2006, Estimate	712	1724	
	2019, Extrapolated	1231	2980	173%

The acoustic detection data published by McCauley and Jenner (2010) revealed a maximum of three pygmy blue whales on a single day passing through the area during their southward migration (November to late December). McCauley and Jenner (2010) estimated the listening range of this noise logger to be 120 km, which is assumed to be a radius, however, to apply precaution in this assessment the recorder listening area was conservatively calculated using a 60 km radius. Based on an average swimming speed for the southbound pygmy blue whales of five knots (9.26 km/hr), McCauley and Jenner (2010) calculated a transit time through the area of 0.54 days; therefore, the number of animals detected per day equates to an estimated density for vocalising animals in the area of 0.0031207 animals per km^2 for their study. As not all animals are emitting calls during their migration, this density estimate has to be corrected for the percentage of animals calling ('calling rate'). McCauley and Jenner (2010) proposed that 8.5–20% of the animals present in an area could be vocalising, considering information relating to humpback whales (8.5%, Cato et al. (2001)), and pygmy blue whales (<20%, (McCauley et al. 2001), to take a precautionary approach this study has adopted the lower bound (8.5%), with the resulting density shown in Table 20, which has been used in this assessment. If the vocalisation rate of pygmy blue whales in the Perth Canyon is applied, the resulting density of vocalising animals would be 2.35 times greater, and thus the correction factor for calling animals would be only 5, rather than 11.76.

The maximum number of three pygmy blue whales per day occurred in associated with the population estimate of 662–1559 whales presented in McCauley and Jenner (2010). If the population increases, it is estimated that the number of whales present on any one day would also increase proportionally. Therefore, the population increase estimate of 4.3% per year, and a corresponding Scaling Factor of 188% (Table 19), has been applied in this study, as shown in Table 20. This results in a revised estimate of the maximum number of animals which could be detected within the listening area per day being 5.64, and a real-world density of 0.0690392 animals per km^2.

Table 20. Density calculations

Variable / Factor	Estimate using data from McCauley and Jenner (2010)	Estimate considering 4.3% population growth since 2004
Number of animals in listening area (animals detected per day in listening area)	3	5.64
Recorder listening area (km^2) (McCauley and Jenner 2010)	11309.73	
Density of Vocalising Animals (animals/km^2)	0.0031207	0.0058683
Calling rate based on humpbacks (8.5% of animals present vocalise)	8.5%	
Correction factor for calling animals	11.76	
Real World Density of animals (D_R) (animals/km^2)	0.03671	0.0690392
Seeded Density (D_S) (animats/km^2)	15	
Scaling Factor (S_D)	0.0024476	0.0046026
Increase in Scaling Factor considering population growth		188%
Comparison of Seeded Density (D_S) to Real World Density of animals (D_R)	408.56	217.27

3.7.3. Green turtles

3.7.3.1. Animal behaviour

Two behavioural profiles were considered for green turtles, inter-nesting and migrating. The research summarised in this section inform the species behavioural definition (Appendix G.3). The migratory behaviour and habitat use of green turtles has been studied at various locations throughout their distribution range for Western Australia, but few studies provide quantitative information on the swim and dive behaviour of these animals.

Studies of the green turtle population nesting on Sandy Islet, Scott Reef by Guinea (2010, 2011), however, include behavioural parameters. Inter-nesting turtle records indicate a maximum dive depth of 45 m and an average dive duration of 15–25 minutes, with a dive duration range of 20 seconds to 55 minutes (Guinea 2011). Migratory turtle records indicate a maximum dive depth of 80 m (average: 49 m) and an average dive duration of 10–15 minutes.

Inter-nesting turtle swimming speeds are not available for the Scott Reef green turtle population. An analogue based on information from a satellite tagging study of green turtle behaviour and movements conducted by the Department of Biodiversity, Conservation and Attractions (DBCA) during the 2018 and 2019 nesting period at Ningaloo has been derived. The inferred average inter-nesting swimming speed for green turtles at Scott Reef adopted for this study was 1.4 km/h.

For the Scott Reef population, the average swim speed of migrating green turtles ranged from 1.3–2.7 km/h (Pendoley 2005, Guinea 2011).

3.7.3.2. Density estimates

Based on beach monitoring at Scott Reef, Guinea (2009) estimated a green turtle abundance of 779 ± 383 (± se) in the years 2008 and 2009. These numbers included counts of green turtles with flipper tags and an estimate from marking and recapturing individuals (identified by sprayed painted carapace) at Sandy Islet. The density of inter-nesting green turtles was defined by the highest estimates of green turtles (1162 individuals) at Scott Reef as recorded by Guinea (2009) and an estimated density of 1.79 turtles/km^2 based on the highest estimate, primarily using an inter-nesting area defined by the 50 m bathymetry around North and South Scott Reef. No density estimates were calculated for migrating green turtles because no data were available.

4. Results

4.1. Pile Driving: Torosa FPSO Anchor Piles

4.1.1. Received levels at 10 m

Since piles are distributed and directional sources, they cannot be accurately approximated by a point source with corresponding source levels. It is possible to compare the maximum modelled levels at short distances from the piles. Figure 16 shows the 1/3-octave-band levels for the receiver with the highest SEL at the closest horizontal range (10 m), for the three modelled penetrations. The levels above 1000 Hz were extrapolated using a 20 dB/decade decay rate to match acoustic measurements of impact pile driving of similarly sized piles (Illingworth & Rodkin 2007, Matuschek and Betke 2009). The modelled results at a distance of 10 m are included to provide results comparable to other pile driving reports and literature, such as Illingworth & Rodkin (2007), and Denes et al. (2016).

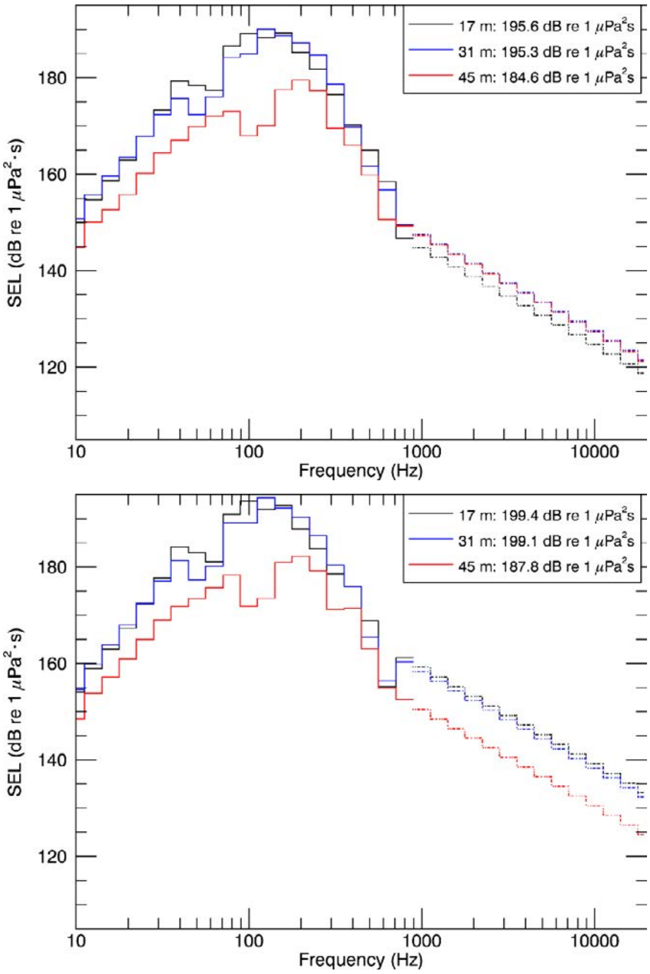

Figure 16. *Torosa*: One-third-octave-band levels for the receiver with highest SEL at 10 m horizontal range for impact pile driving using the IHC S-600 (top) and the IHC S-1200 (bottom), after high-frequency extrapolation (dashes indicate extrapolated portion of the spectrum). Legend items indicate the modelled pile penetration (Table 16) and the broadband SEL in dB re 1 μPa²·s.

4.1.2. Per-strike sound fields

Per-strike results for the proposed pile driving are presented in this section for maximum-over-depth SPL, SEL, and PK (tables in Section 4.1.2.1), maps and sound field vertical slices (Section 4.1.2.2).

4.1.2.1. Tabulated results

Tables 21–26 show the estimated distances for the various applicable per-strike effects criteria and isopleths of interest as maximum-over-depth.

Table 21. *Torosa piling, per-strike SEL:* Maximum (R_{max}) and 95% ($R_{95\%}$) horizontal distances (in km) from the pile to modelled maximum-over-depth isopleths.

4.1.2.2. Sound field maps and vertical slices

Maps of the per-strike SPL results associated with the three modelled penetration depths are shown in Figures 17, 18, and 19 for the IHC S-600, and in Figures 20, 21, and 22 for the IHC S-1200. Per-strike SEL maps are shown in Appendix H.1. For each hammer, the shallowest modelled penetration has the farthest distances to all per-strike isopleths. Additionally, maps showing the isopleths for marine mammal behavioural criteria (160 dB re 1 µPa) for each of the three considered penetration depths are provided in Figures 23 and 24 for the IHC S-600 and the IHC S-1200, respectively, to demonstrate visually the reduction in extent with increased penetration depth. Vertical slice plots for all penetrations are shown in Figures 25–27 (IHC S-600) and Figures 28–30 (IHC S-1200).

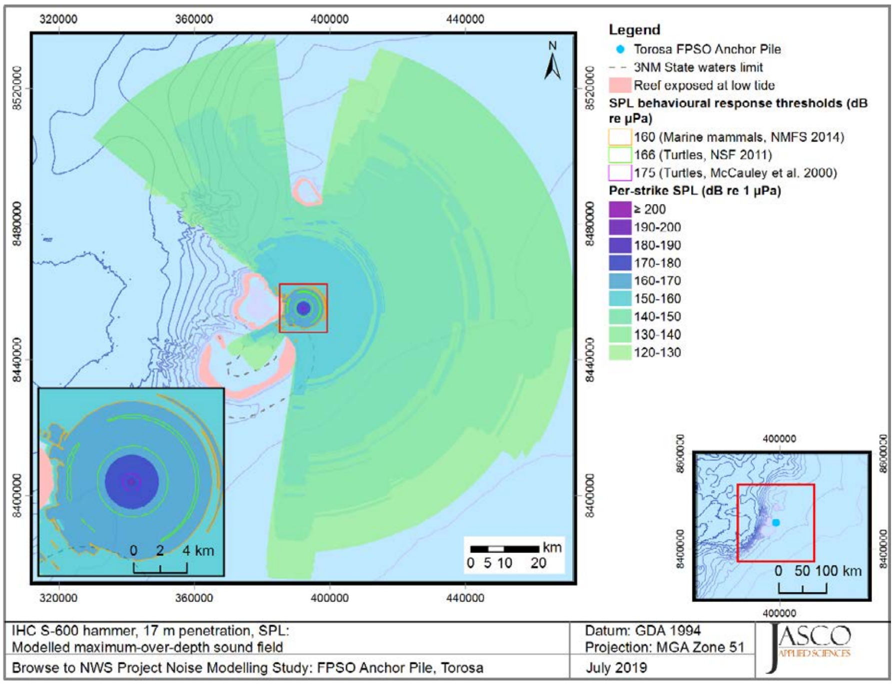

Figure 17. *Torosa, IHC S-600, SPL, 17 m penetration depth*: Sound level contour map, showing maximum-over-depth results. Isopleths for turtles (166 and 175 dB re 1 µPa) and marine mammal (160 dB re 1 µPa) behavioural criteria are shown.

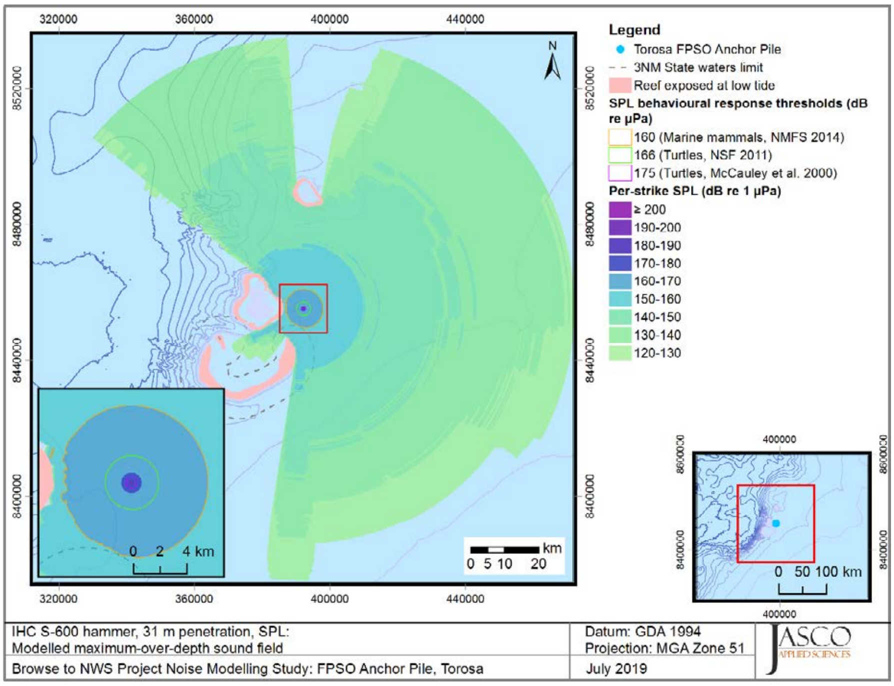

Figure 18. *Torosa, IHC S-600, SPL, 31 m penetration depth*: Sound level contour map, showing maximum-over-depth results. Isopleths for turtles (166 and 175 dB re 1 µPa) and marine mammal (160 dB re 1 µPa) behavioural criteria are shown.

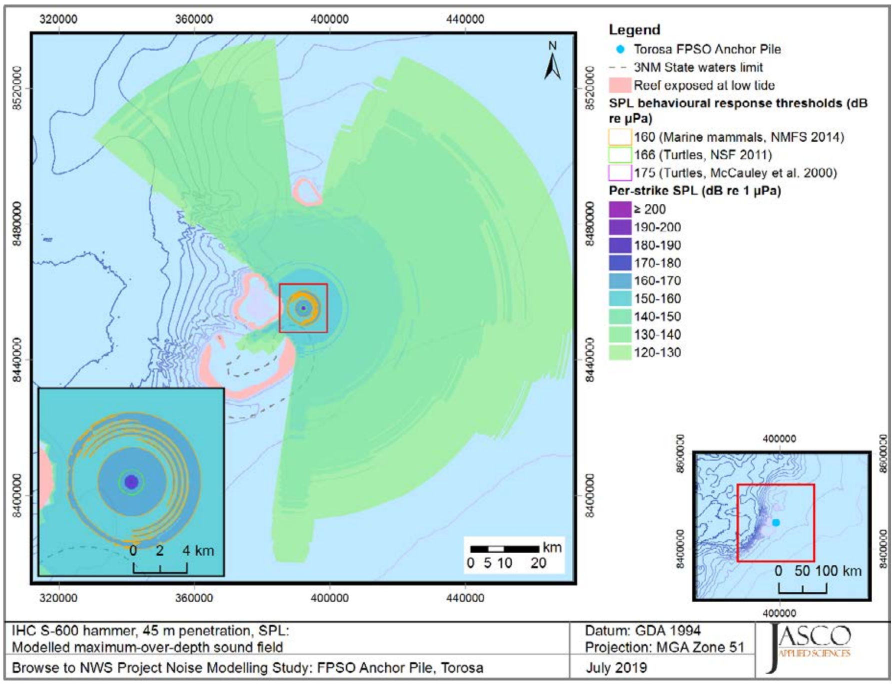

Figure 19. *Torosa, IHC S-600, SPL, 45 m penetration depth*: Sound level contour map, showing maximum-over-depth results. Isopleths for turtles (166 and 175 dB re 1 µPa) and marine mammal (160 dB re 1 µPa) behavioural criteria are shown.

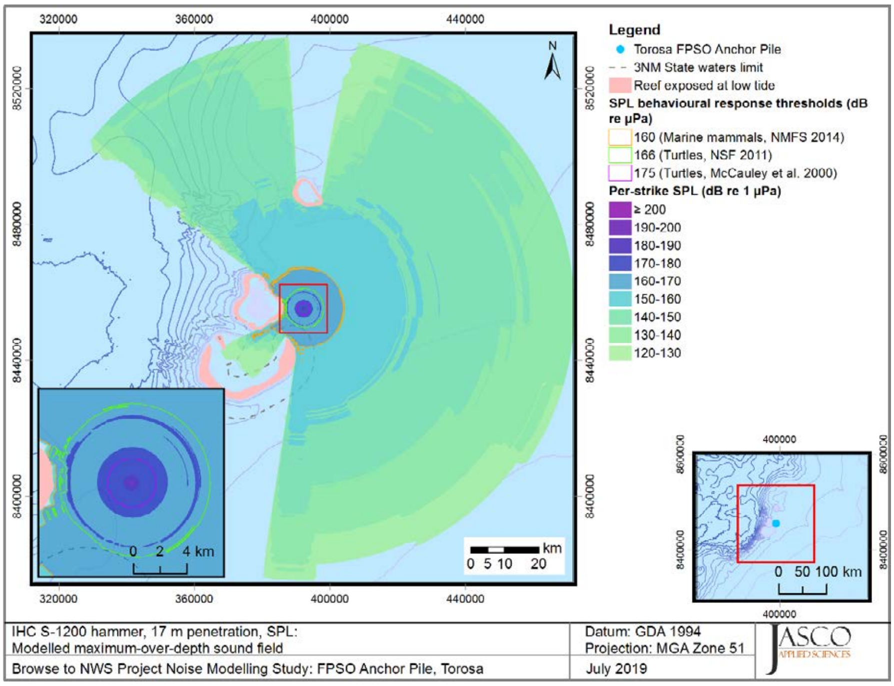

Figure 20. *Torosa, IHC S-1200, SPL, 17 m penetration depth*: Sound level contour map, showing unweighted maximum-over-depth results. Isopleths for turtles (166 and 175 dB re 1 µPa) and marine mammal (160 dB re 1 µPa) behavioural criteria are shown.

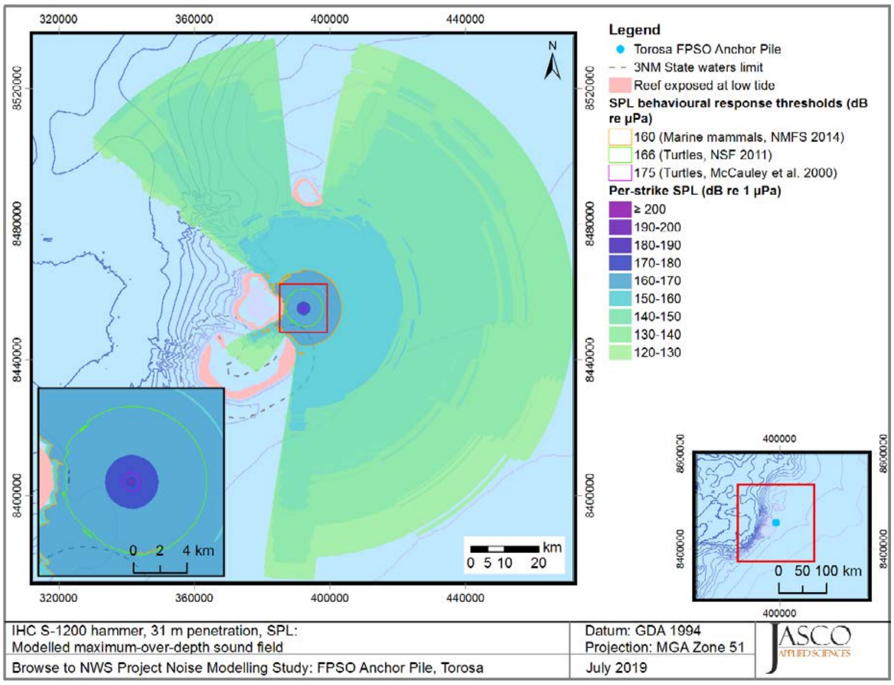

Figure 21. *Torosa, IHC S-1200, SPL, 31 m penetration depth*: Sound level contour map, showing maximum-over-depth results. Isopleths for turtles (166 and 175 dB re 1 µPa) and marine mammal (160 dB re 1 µPa) behavioural criteria are shown.

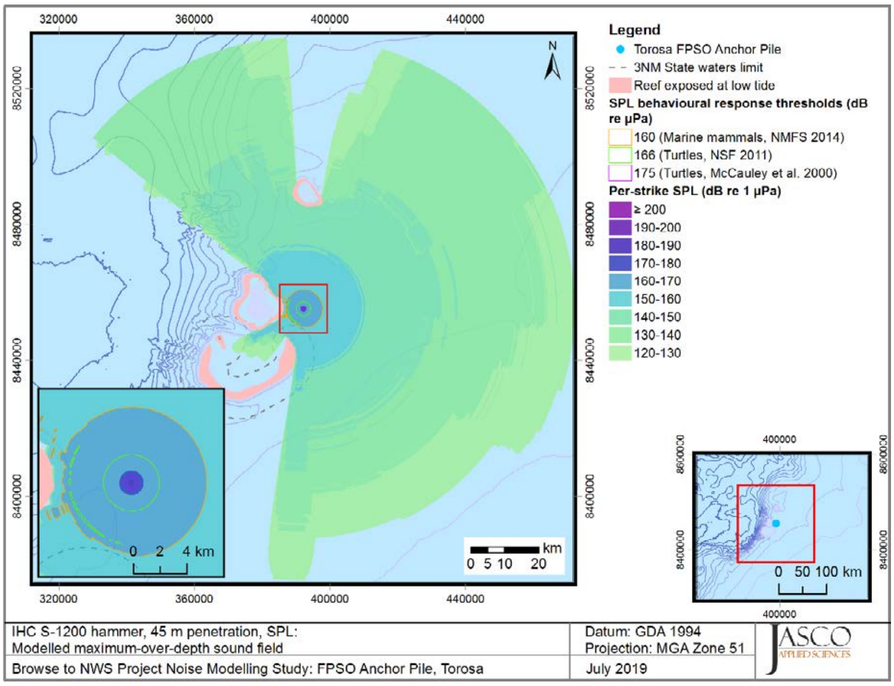

Figure 22. *Torosa, IHC S-1200, SPL, 45 m penetration depth*: Sound level contour map, showing maximum-over-depth results. Isopleths for turtles (166 and 175 dB re 1 µPa) and marine mammal (160 dB re 1 µPa) behavioural criteria are shown.

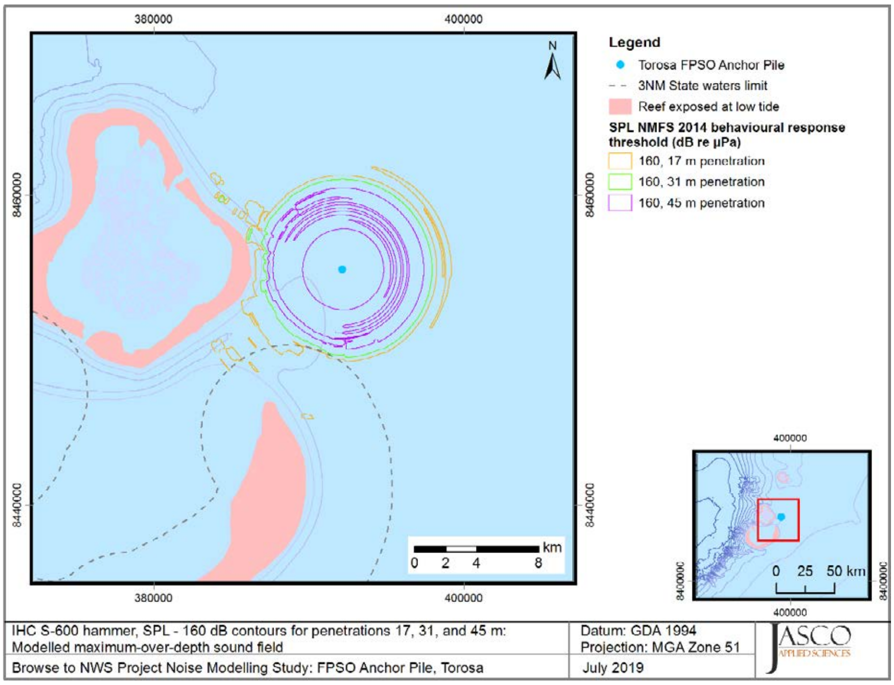

Figure 23. *Torosa, IHC S-600, SPL*: Sound level contour map showing unweighted maximum-over-depth SPL marine mammal (160 dB re 1 µPa) behavioural criteria results for all modelled penetration depths.

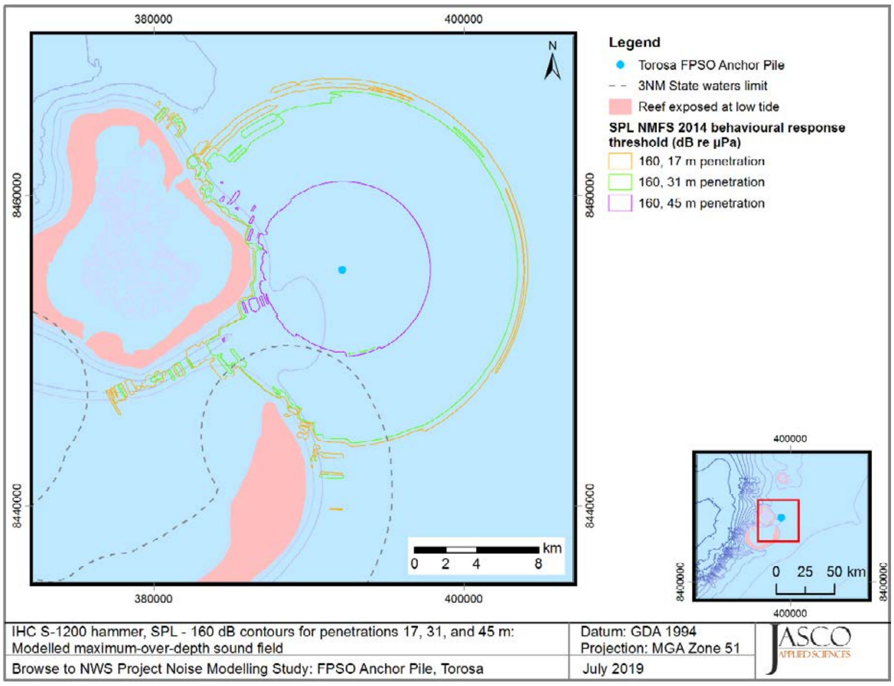

Figure 24. *Torosa, IHC S-1200, SPL*: Sound level contour map showing unweighted maximum-over-depth SPL marine mammal (160 dB re 1 µPa) behavioural criteria results for all modelled penetration depths.

4.1.2.2.1. Vertical slice plots

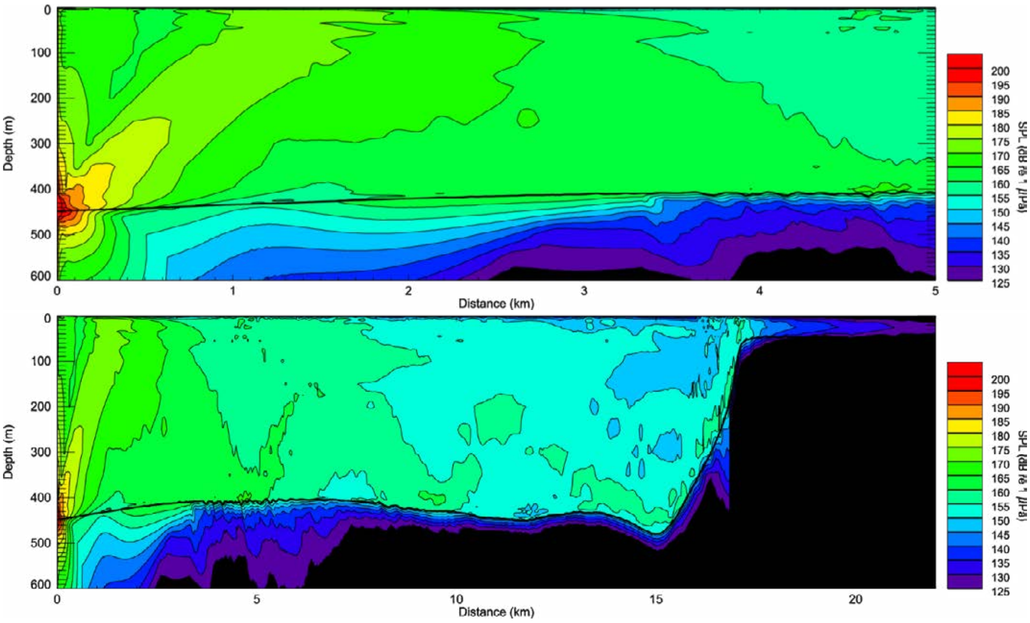

Figure 25. *Torosa, vertical slice, IHC S-600, SPL, 17 m penetration depth*: 0–5 km (top) and 0–22 km (bottom). Levels are shown along a single transect of azimuth 240°. The seabed outline is shown as a thick black line.

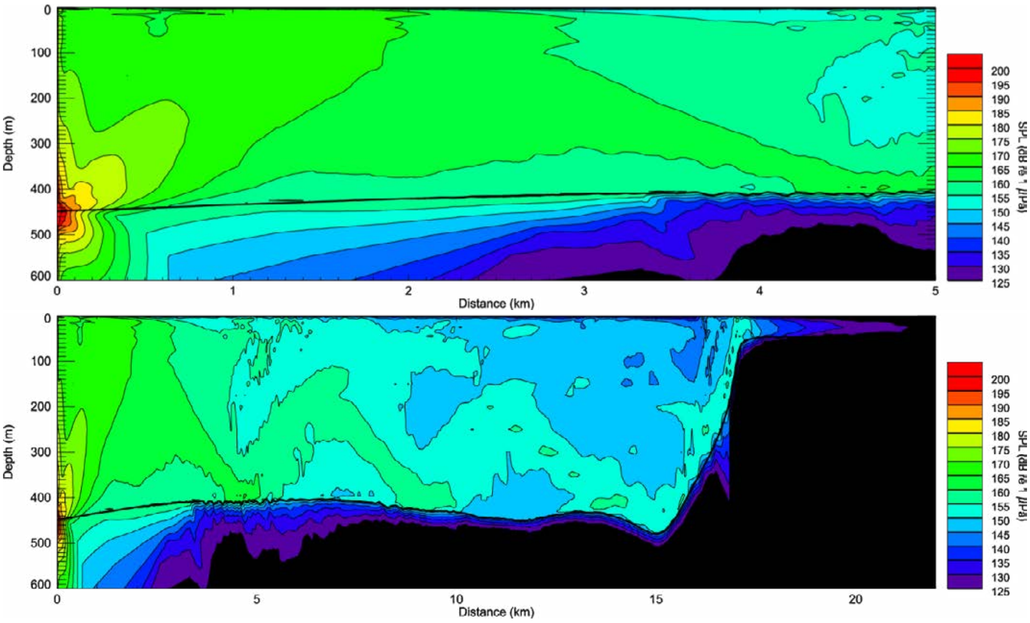

Figure 26. *Torosa, vertical slice, IHC S-600, SPL, 31 m penetration depth*: 0–5 km (top) and 0–22 km (bottom). Levels are shown along a single transect of azimuth 240°. The seabed outline is shown as a thick black line.

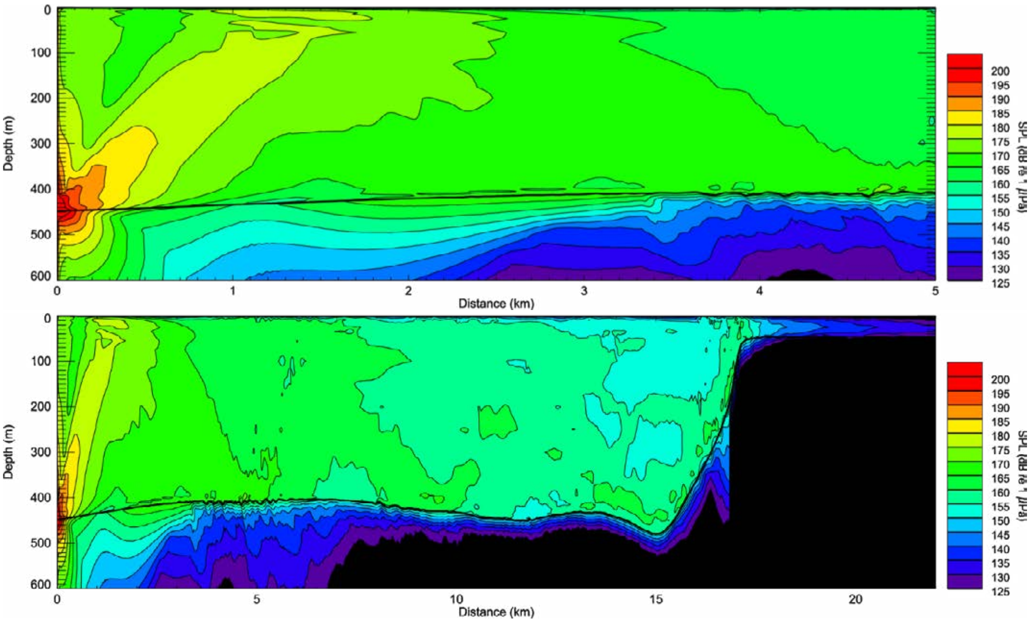

Figure 27. *Torosa, vertical slice, IHC S-600, SPL, 45 m penetration depth*: 0–5 km (top) and 0–22 km (bottom). Levels are shown along a single transect of azimuth 240°. The seabed outline is shown as a thick black line.

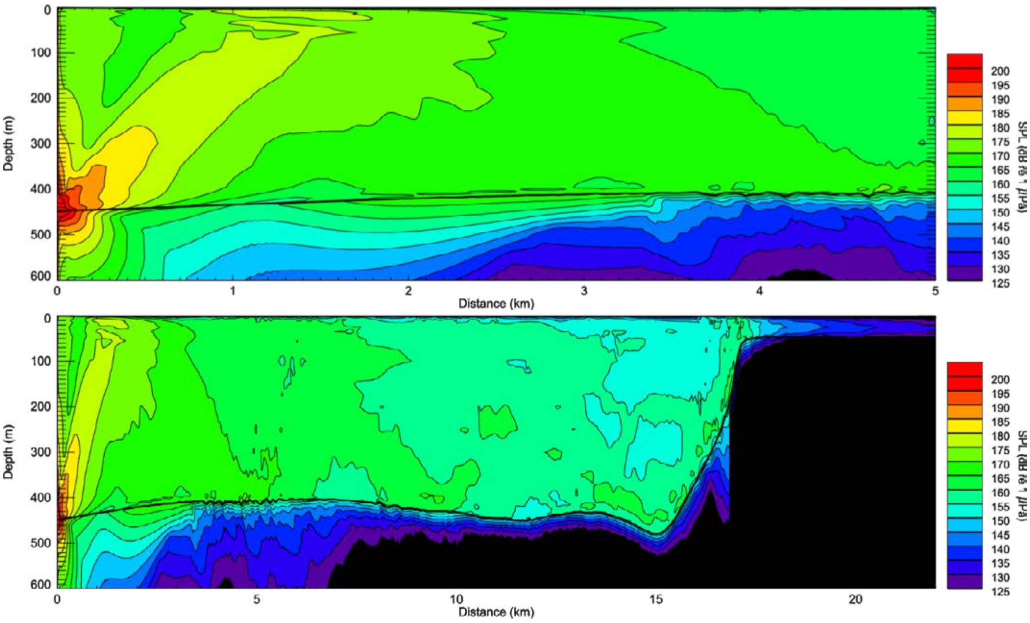

Figure 28. *Torosa, vertical slice, IHC S-1200, SPL, 17 m penetration depth*: 0–5 km (top) and 0–22 km (bottom). Levels are shown along a single transect of azimuth 240°. The seabed outline is shown as a thick black line.

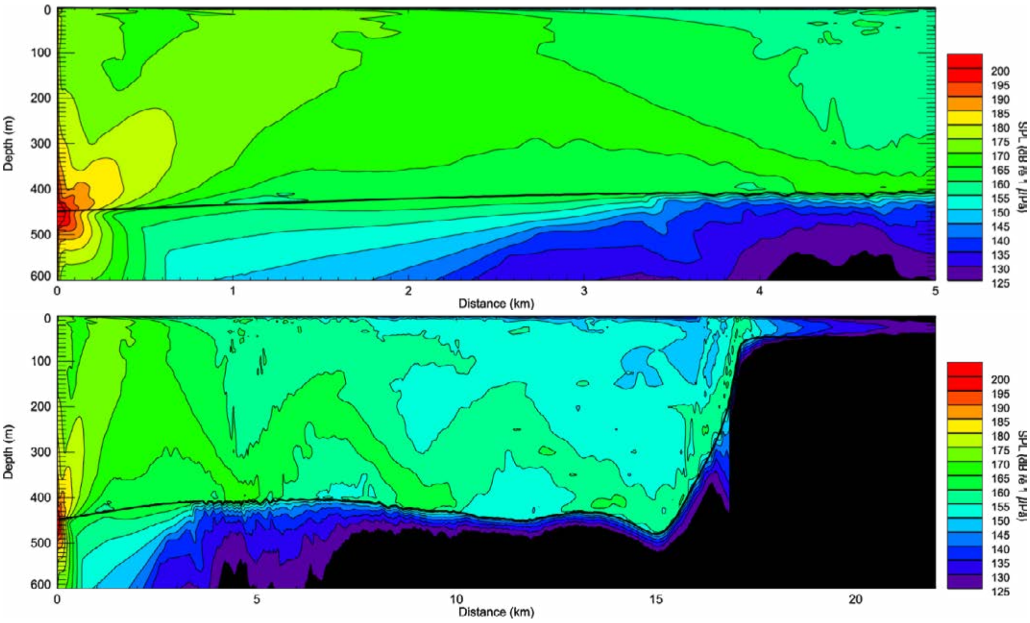

Figure 29. *Torosa, vertical slice, IHC S-1200, SPL, 31 m penetration depth*: 0–5 km (top) and 0–22 km (bottom). Levels are shown along a single transect of azimuth 240°. The seabed outline is shown as a thick black line.

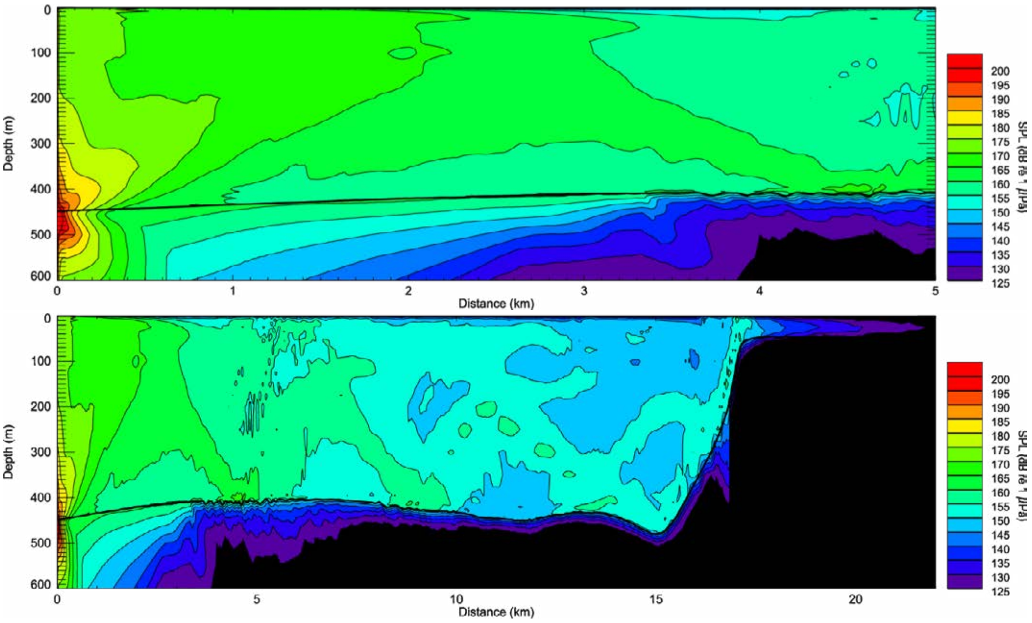

Figure 30. *Torosa, vertical slice, IHC S-1200, SPL, 45 m penetration depth*: 0–5 km (top) and 0–22 km (bottom). Levels are shown along a single transect of azimuth 240°. The seabed outline is shown as a thick black line.

Detailed plots of the sound fields along two transects for both the IHC S-600 and IHC S-1200 hammers relevant to the pygmy blue whale migratory behavioural profile (Table G-2) are shown in Figures 31–34. These plots highlight 1) the mean migratory dive depth (14 m), 2) 23 m – almost the deepest point of the migratory dives but the start point for exploratory dives, 3) the mean exploratory dive depth (107 m), and 4) the deepest point for exploratory dives (320 m), with all values from Owen et al. (2016).

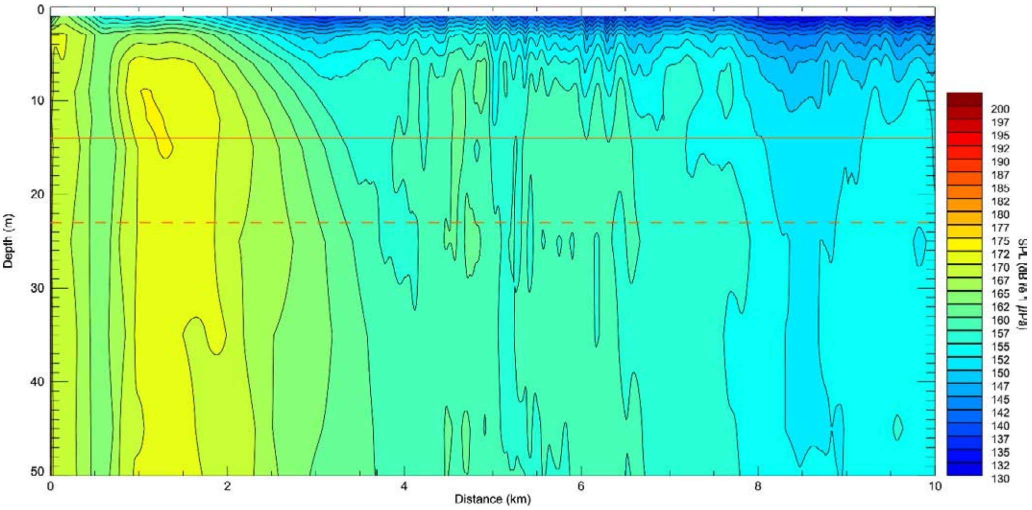

Figure 31. *Torosa, vertical slice, IHC S-600, SPL, 17 m penetration depth*: Levels are shown along a single transect of azimuth 240°, out to 10 km range, and down to 50 m depth, highlighting the depths of 14 and 23 m.

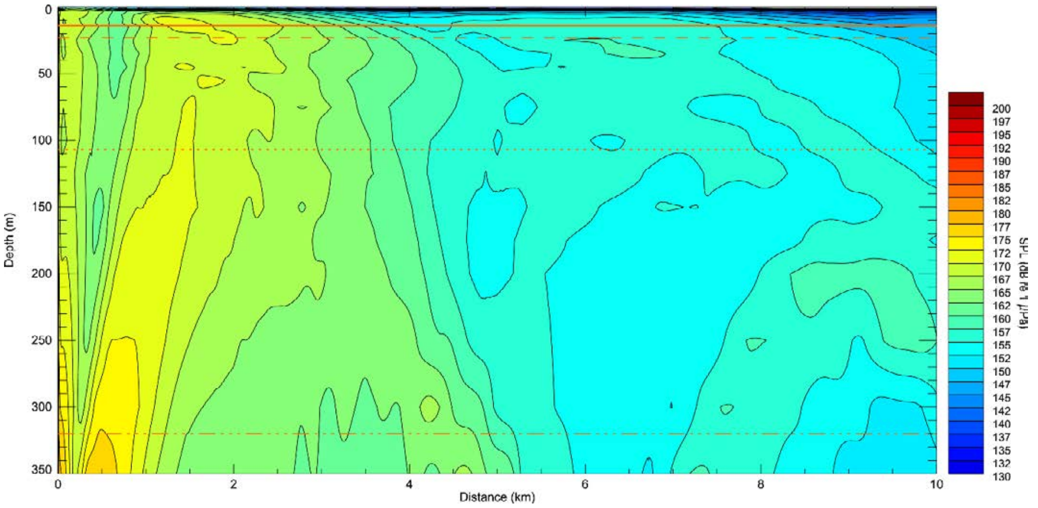

Figure 32. *Torosa, vertical slice, IHC S-600, SPL, 17 m penetration depth*: Levels are shown along a single transect of azimuth 240°, out to 10 km range, and down to 350 m depth, highlighting the depths of 14, 23, 107 and 320 m.

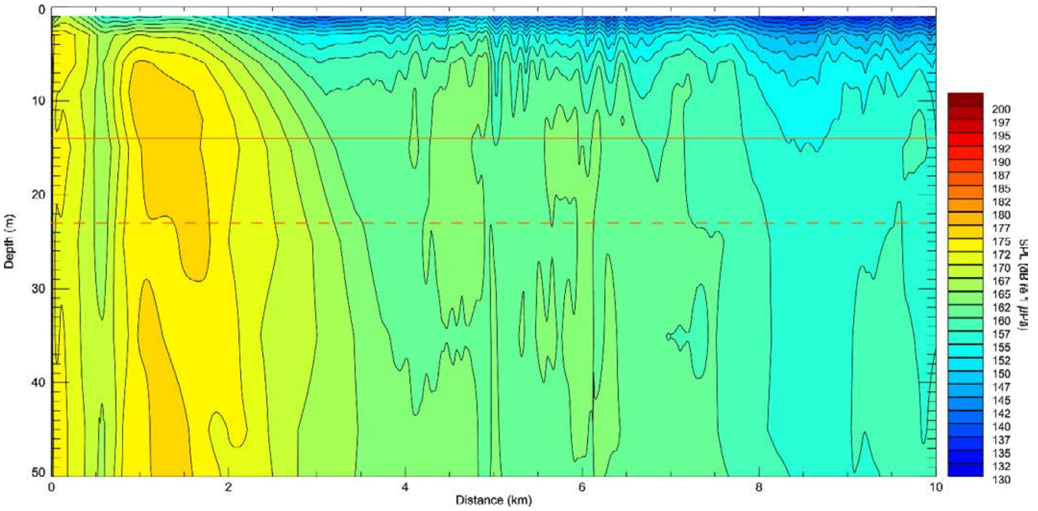

Figure 33. *Torosa, vertical slice, IHC S-1200, SPL, 17 m penetration depth*: Levels are shown along a single transect of azimuth 240°, out to 10 km range, and down to 50 m depth, highlighting the depths of 14 and 23 m.

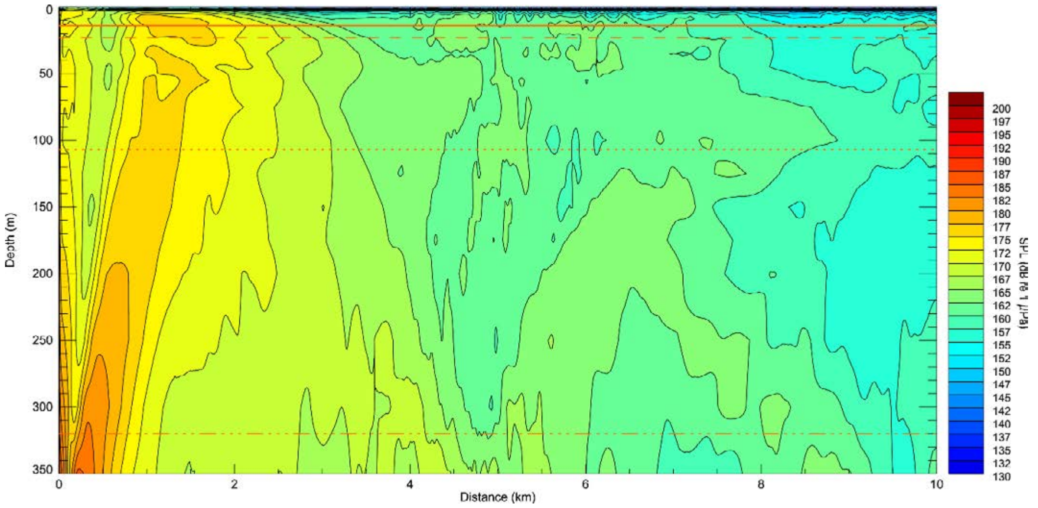

Figure 34. *Torosa, vertical slice, IHC S-1200, SPL, 17 m penetration depth*: Levels are shown along a single transect of azimuth 240°, out to 10 km range, and down to 350 m depth, highlighting the depths of 14, 23, 107 and 320 m.

4.1.3. Multiple Strike Sound Fields

Table 27 presents the SEL24h results relevant to marine mammals for the proposed pile driving operations, while Table 28 shows modelled distances to the cumulative exposure criteria contours for fish, fish eggs and larvae. The sound levels at the Scott Reef coastal waters limit are shown in Table 29. The sound level contour maps for cetaceans and turtles are presented in Figures 35 and 36 for the IHC S-600 and the IHC S-1200 hammers, respectively. The sound level contour maps for fish are presented in Figures 37 and 38 for the IHC S-600 and the IHC S-1200 hammers, respectively.

Table 27. *Torosa piling, SEL_{24}*: Maximum-over-depth distances (in km) to frequency-weighted SEL_{24h} based marine mammal PTS and TTS thresholds (NMFS 2018) and turtles (Finneran et al. 2017).

4.1.4. Animal Movement and Exposure Modelling

Summaries of the animat modelling results for inter-nesting and migrating green turtles are provided in Table 30, while those for migrating and foraging pygmy blue whales are provided in Table 31.

Table 30. *Torosa*: Summary of animat simulation results for migratory and inter-nesting turtles. Includes the distances to acoustic modelling thresholds (km), the 95th percentile exposure ranges (km), and the number of real-world individuals exposed above threshold (where densities are available). This summary includes both the original animat simulation results and the results excluding animats within a 500 m zone surrounding the pile, acoustic modelling results are presented in Tables 23, 24, and 27.

4.2. Pile Driving: Brecknock FPSO Anchor Piles

4.2.1. Received levels at 10 m

Since piles are distributed and directional sources, they cannot be accurately approximated by a point source with corresponding source levels. It is possible to compare the maximum modelled levels at short distances from the piles. Figure 39 shows the 1/3-octave-band levels for the receiver with the highest SEL at the closest horizontal range (10 m), for the three modelled penetrations. The levels above 1000 Hz were extrapolated using a 20 dB/decade decay rate to match acoustic measurements of impact pile driving of similarly sized piles (Illingworth & Rodkin 2007, Matuschek and Betke 2009). The modelled results at a distance of 10 m are included to provide results comparable to other pile driving reports and literature, such as Illingworth & Rodkin (2007), and Denes et al. (2016).

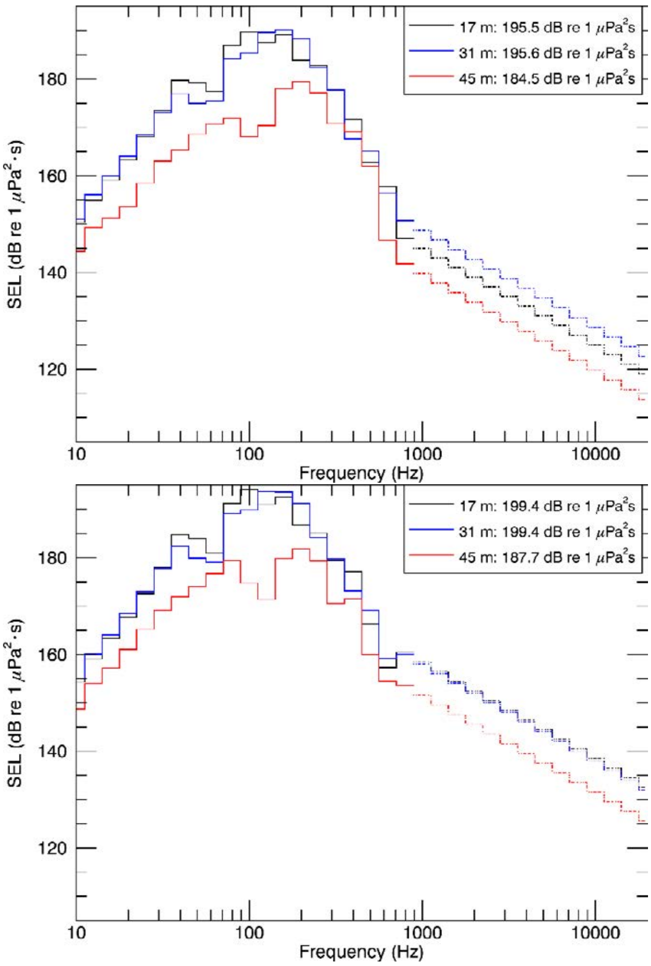

Figure 39. *Brecknock*: One-third-octave-band levels for the receiver with highest SEL at 10 m horizontal range for impact pile driving using the IHC S-600 (top) and the IHC S-1200 (bottom), after high-frequency extrapolation (dashes indicate extrapolated portion of the spectrum). Legend items indicate the modelled pile penetration (Table 16) and the broadband SEL in dB re 1 μPa^2·s.

4.2.2. Per-strike sound fields

Per-strike results for the proposed pile driving are presented in this section for maximum-over-depth SPL, SEL, and PK (tables in Section 4.2.2.1), maps and sound field vertical slices (Section 4.2.2.2).

4.2.2.1. Tabulated results

Tables 32–36 show the estimated distances for the various applicable per-strike effects criteria and isopleths of interest as maximum-over-depth.

Table 32. *Brecknock piling, per-strike SEL:* Maximum (R_{max}) and 95% ($R_{95\%}$) horizontal distances (in km) from the pile to modelled maximum-over-depth isopleths.

4.2.2.2. Sound field maps and vertical slices

Maps of the per-strike SPL results associated with the three modelled penetration depths are shown in Figures 40, 41, and 42 for the IHC S-600, and in Figures 43, 44, and 45 for the IHC S-1200. Per-strike SEL maps are shown in Appendix H.2. For each hammer, the shallowest modelled penetration has the farthest distances to all per-strike isopleths. Additionally, maps showing the isopleths for marine mammal behavioural criteria (160 dB re 1 µPa) for each of the three considered penetration depths are provided in Figures 46 and 47 for the IHC S-600 and the IHC S-1200, respectively, to demonstrate visually the reduction in extent with increased penetration depth. Vertical slice plots for all penetrations are shown in Figures 48–50 (IHC S-600) and Figures 51–53 (IHC S-1200).

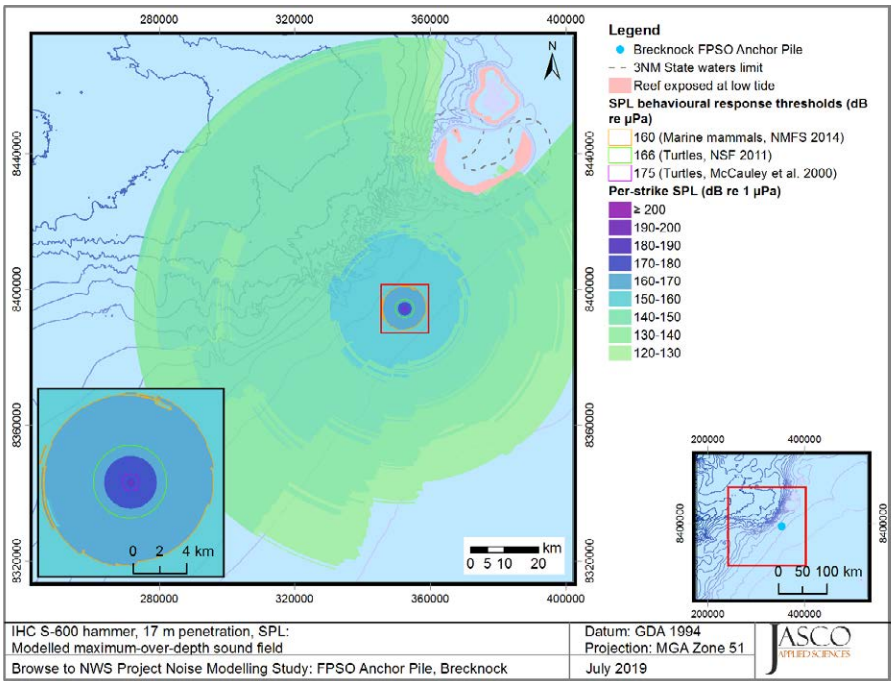

Figure 40. *Brecknock, IHC S-600, SPL, 17 m penetration depth*: Sound level contour map, showing maximum-over-depth results. Isopleths for turtles (166 and 175 dB re 1 µPa) and marine mammal (160 dB re 1 µPa) behavioural criteria are shown.

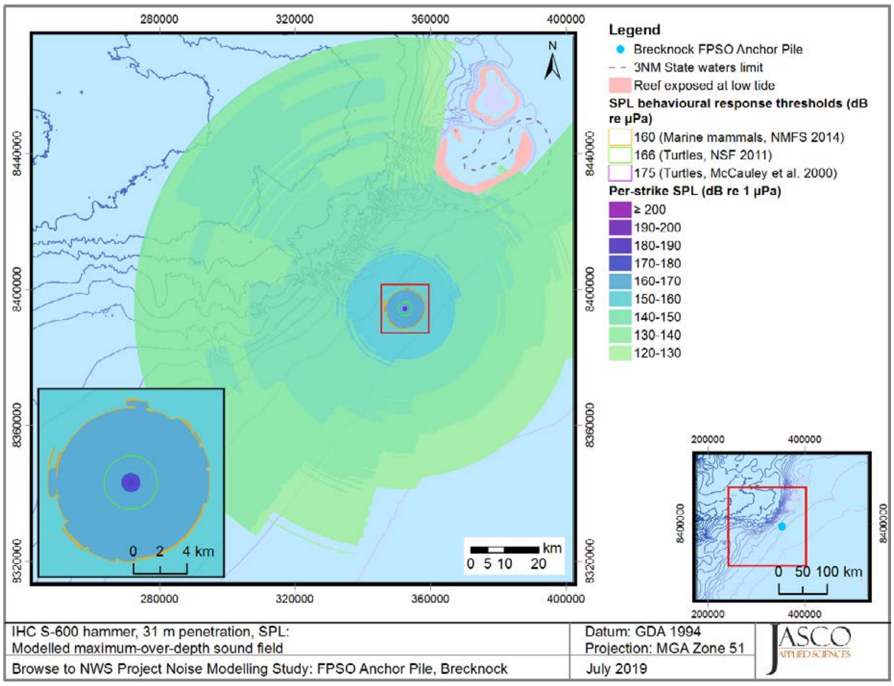

Figure 41. *Brecknock, IHC S-600, SPL, 31 m penetration depth*: Sound level contour map, showing maximum-over-depth results. Isopleths for turtles (166 and 175 dB re 1 µPa) and marine mammal (160 dB re 1 µPa) behavioural criteria are shown.

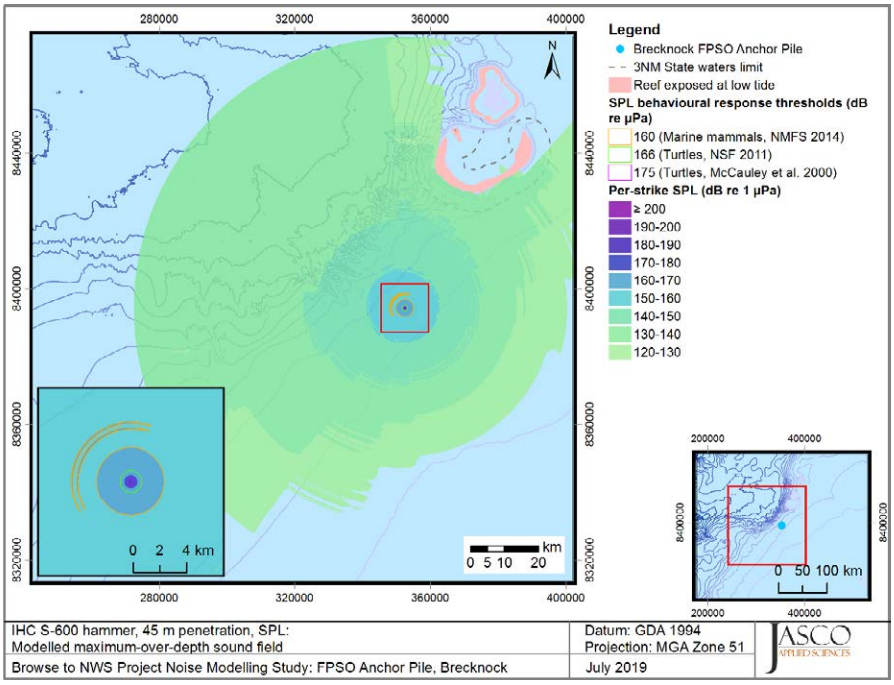

Figure 42. *Brecknock, IHC S-600, SPL, 45 m penetration depth*: Sound level contour map, showing maximum-over-depth results. Isopleths for turtles (166 and 175 dB re 1 µPa) and marine mammal (160 dB re 1 µPa) behavioural criteria are shown.

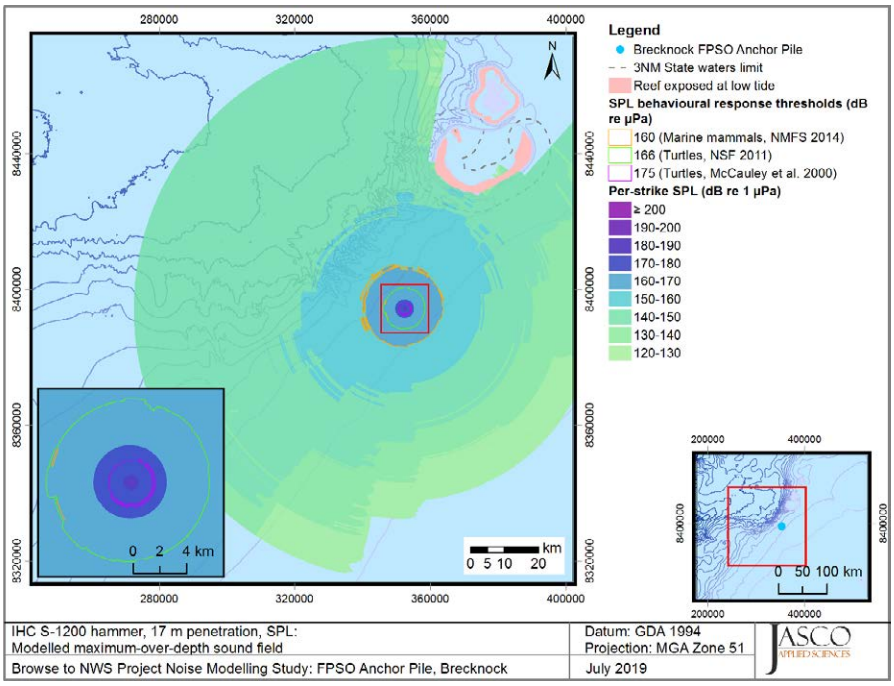

Figure 43. *Brecknock, IHC S-1200, SPL, 17 m penetration depth*: Sound level contour map, showing unweighted maximum-over-depth results. Isopleths for turtles (166 and 175 dB re 1 µPa) and marine mammal (160 dB re 1 µPa) behavioural criteria are shown.

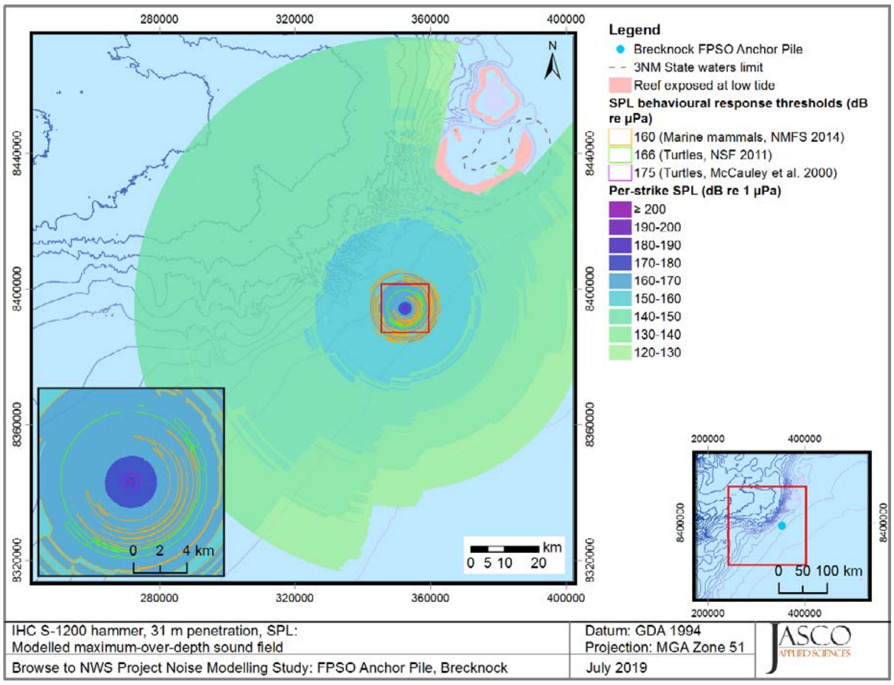

Figure 44. *Brecknock, IHC S-1200, SPL, 31 m penetration depth*: Sound level contour map, showing maximum-over-depth results. Isopleths for turtles (166 and 175 dB re 1 µPa) and marine mammal (160 dB re 1 µPa) behavioural criteria are shown.

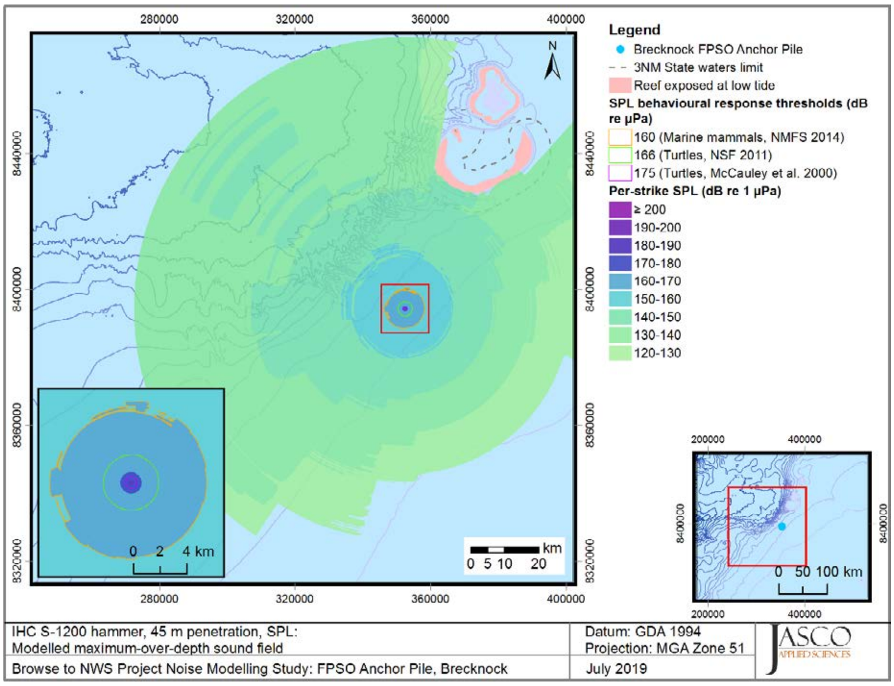

Figure 45. *Brecknock, IHC S-1200, SPL, 45 m penetration depth*: Sound level contour map, showing maximum-over-depth results. Isopleths for turtles (166 and 175 dB re 1 µPa) and marine mammal (160 dB re 1 µPa) behavioural criteria are shown.

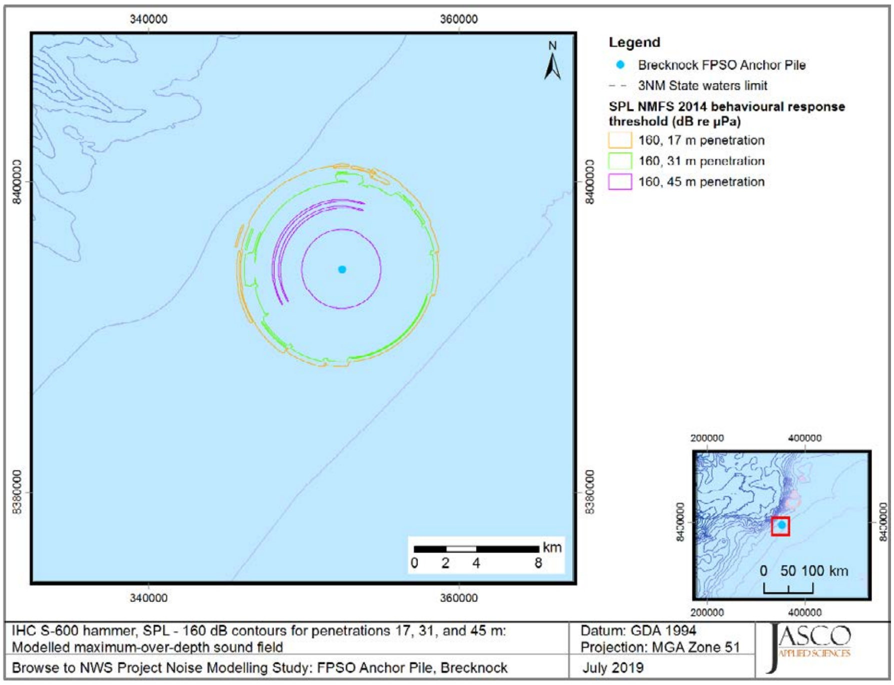

Figure 46. *Brecknock, IHC S-600, SPL*: Sound level contour map showing unweighted maximum-over-depth SPL marine mammal (160 dB re 1 µPa) behavioural criteria results for all modelled penetration depths.

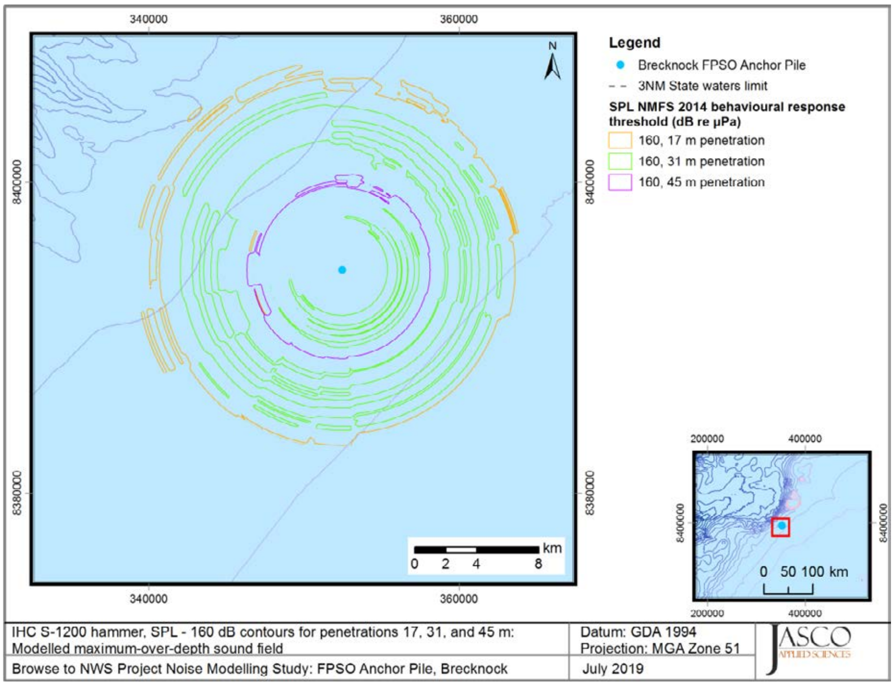

Figure 47. *Brecknock, IHC S-1200, SPL*: Sound level contour map showing unweighted maximum-over-depth SPL marine mammal (160 dB re 1 µPa) behavioural criteria results for all modelled penetration depths.

4.2.2.2.1. Vertical slice plots

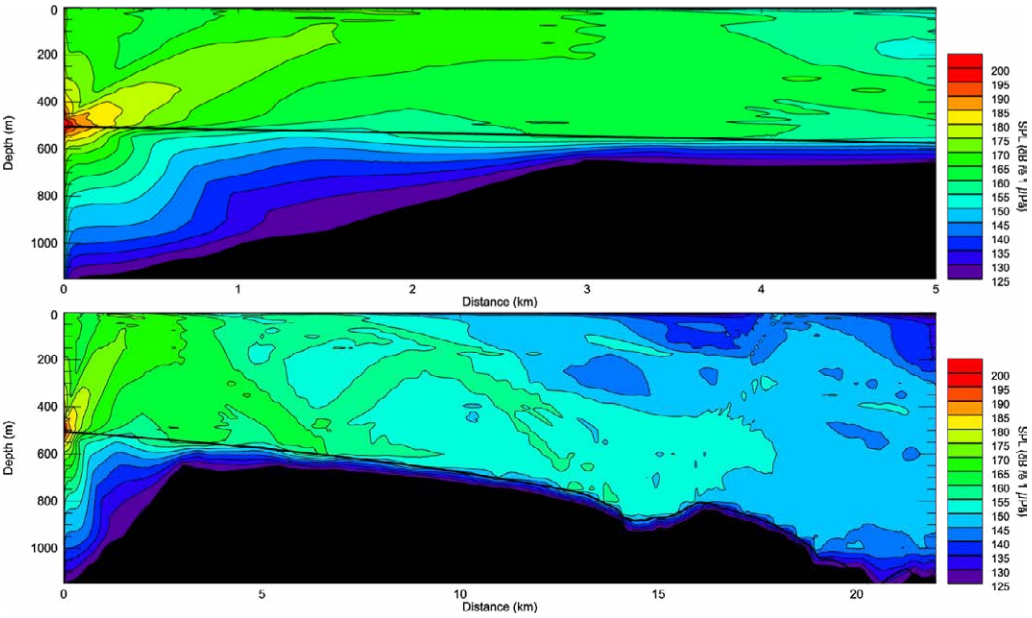

Figure 48. *Brecknock, vertical slice, IHC S-600, SPL, 17 m penetration depth*: 0–5 km (top) and 0–22 km (bottom). Levels are shown along a single transect of azimuth 315°. The seabed outline is shown as a thick black line.

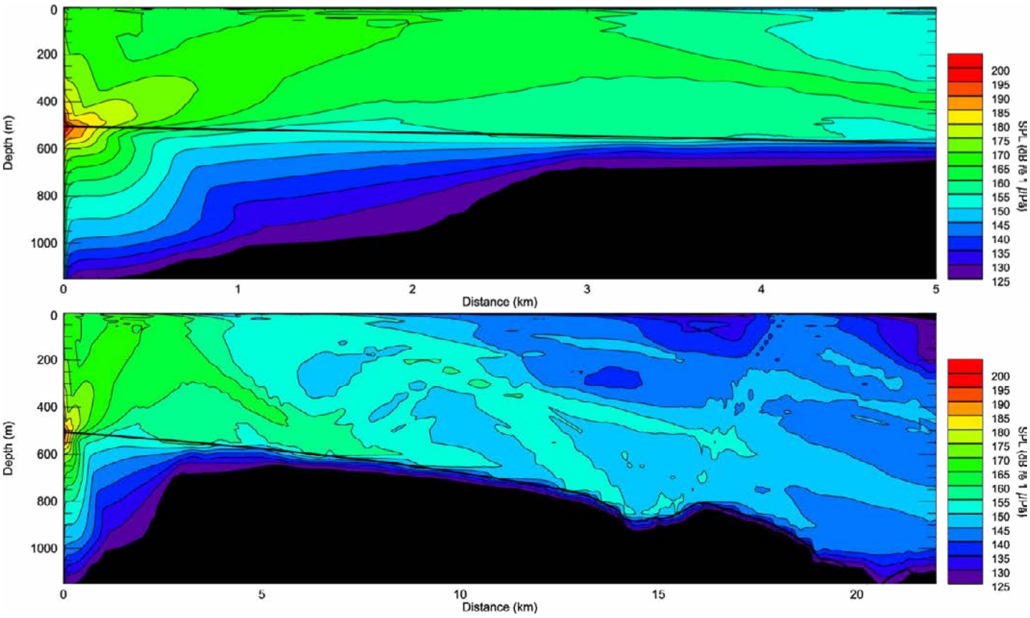

Figure 49. *Brecknock, vertical slice, IHC S-600, SPL, 31 m penetration depth*: 0–5 km (top) and 0–22 km (bottom). Levels are shown along a single transect of azimuth 315°. The seabed outline is shown as a thick black line.

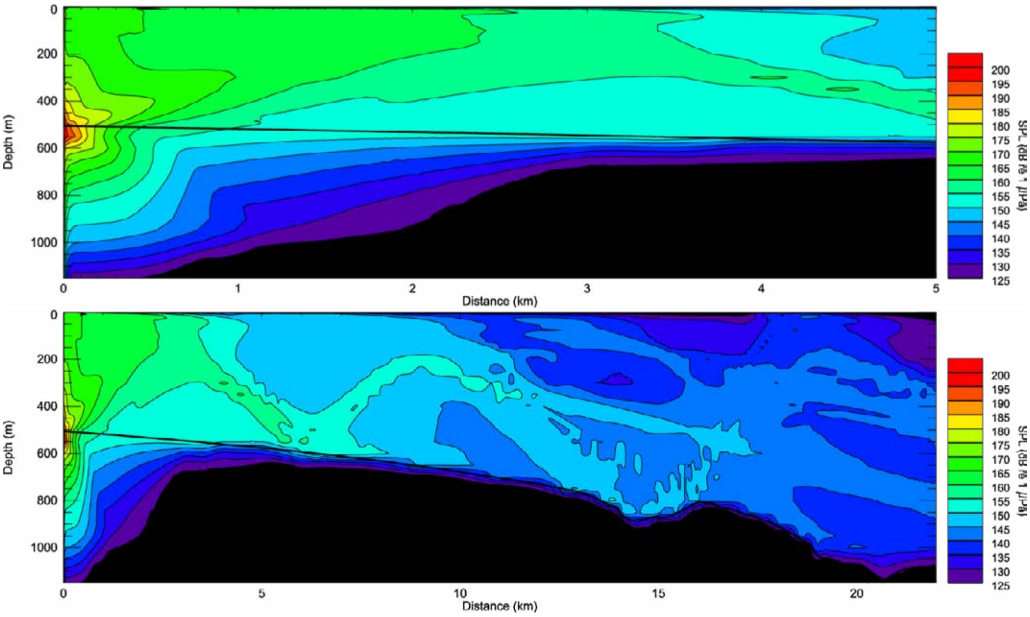

Figure 50. *Brecknock, vertical slice, IHC S-600, SPL, 45 m penetration depth*: 0–5 km (top) and 0–22 km (bottom). Levels are shown along a single transect of azimuth 315°. The seabed outline is shown as a thick black line.

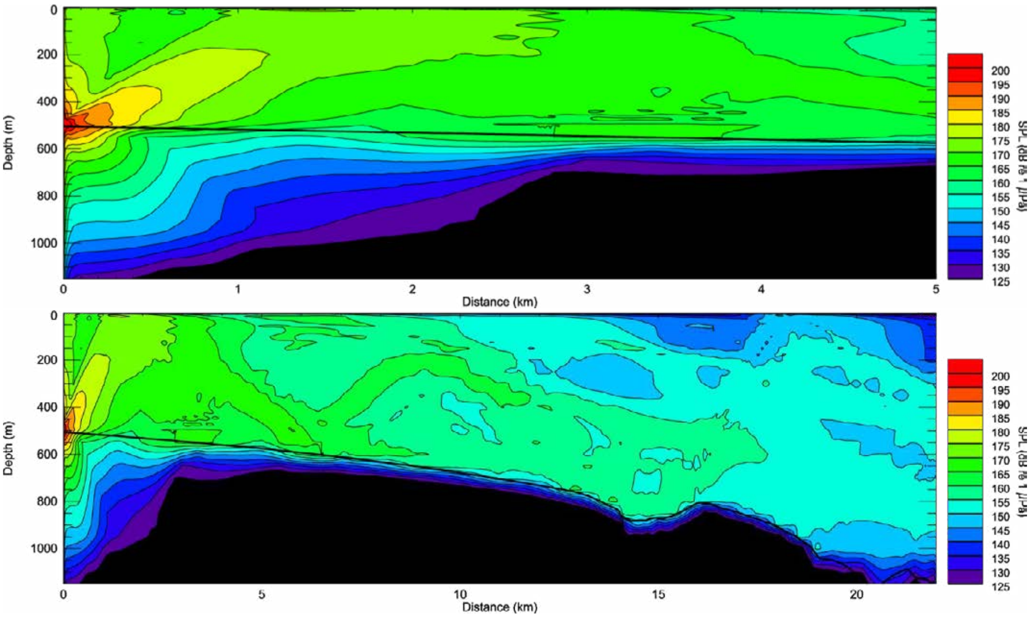

Figure 51. *Brecknock, vertical slice, IHC S-1200, SPL, 17 m penetration depth*: 0–5 km (top) and 0–22 km (bottom). Levels are shown along a single transect of azimuth 315°. The seabed outline is shown as a thick black line.

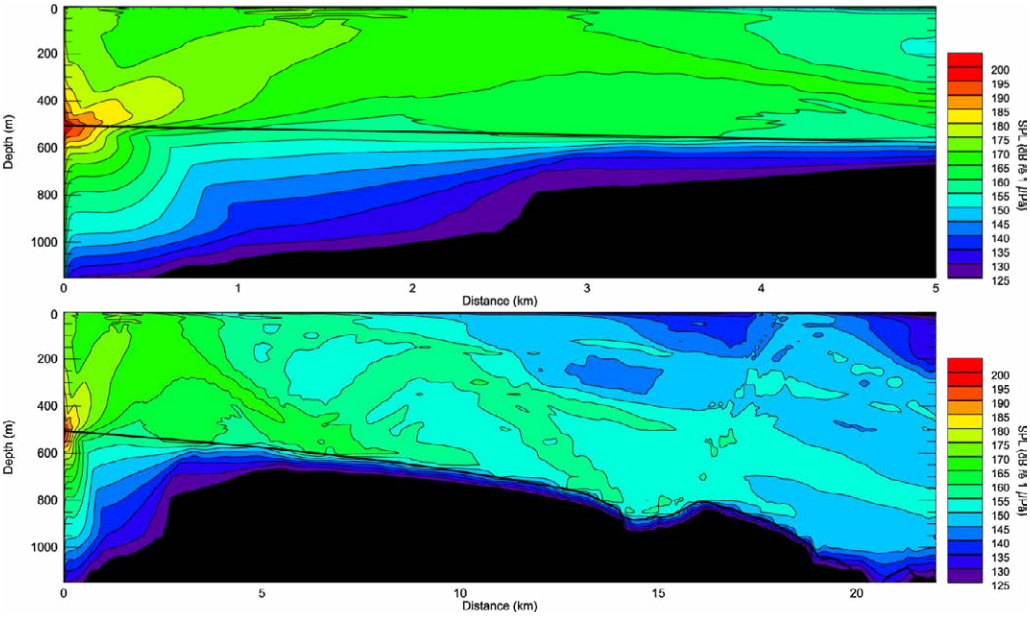

Figure 52. *Brecknock, vertical slice, IHC S-1200, SPL, 31 m penetration depth*: 0–5 km (top) and 0–22 km (bottom). Levels are shown along a single transect of azimuth 315°. The seabed outline is shown as a thick black line.

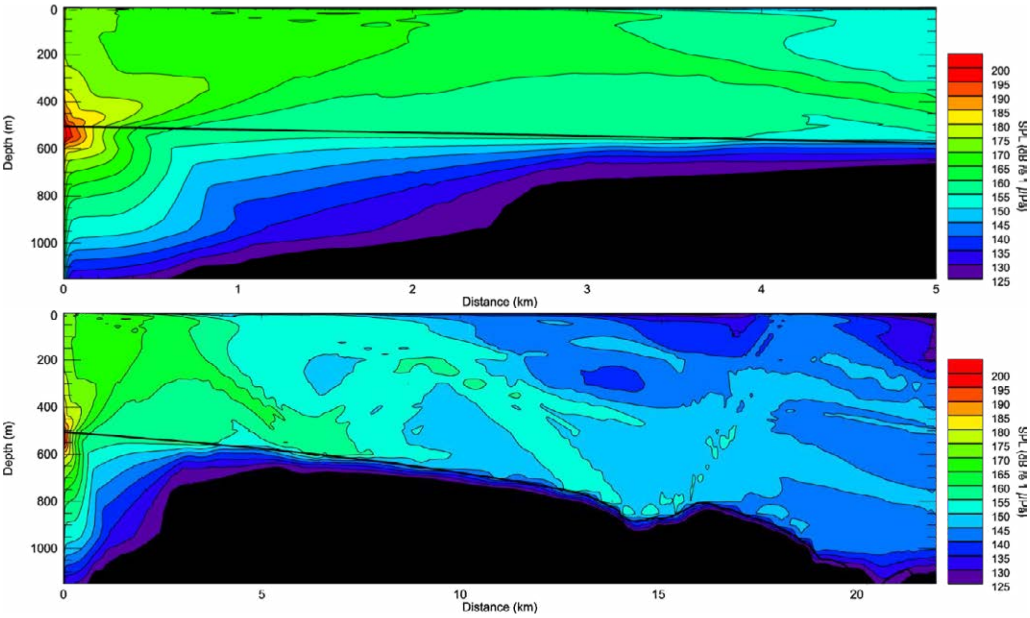

Figure 53. *Brecknock, vertical slice, IHC S-1200, SPL, 45 m penetration depth*: 0–5 km (top) and 0–22 km (bottom). Levels are shown along a single transect of azimuth 315°. The seabed outline is shown as a thick black line.

Detailed plots of the sound fields along two transects for both the IHC S-600 and IHC S-1200 hammers relevant to the pygmy blue whale migratory behavioural profile (Table G-2) are shown in Figures 58–61. These plots highlight 1) the mean migratory dive depth (14 m), 2) 23 m – almost the deepest point of the migratory dives but the start point for exploratory dives, 3) the mean exploratory dive depth (107 m), and 4) the deepest point for exploratory dives (320 m), with all values from Owen et al. (2016).

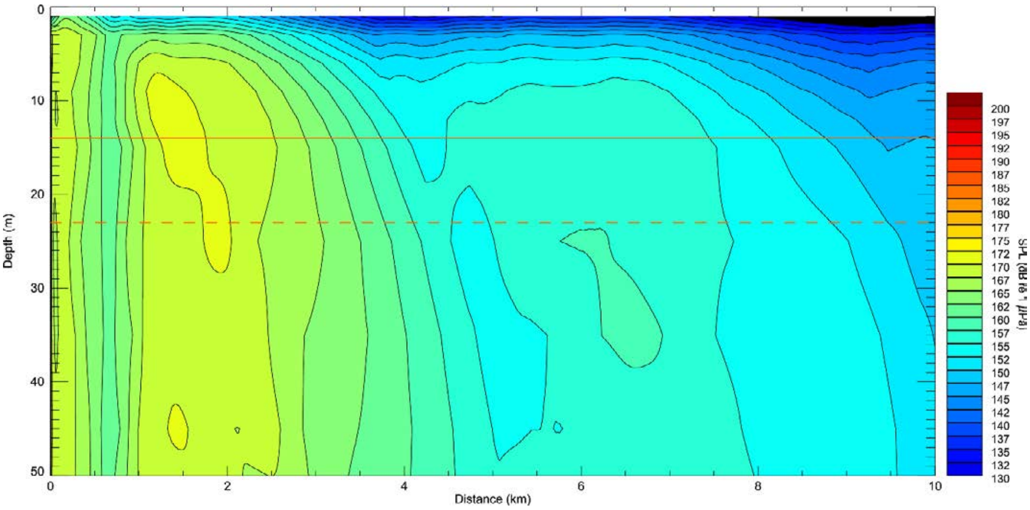

Figure 54. *Brecknock, vertical slice, IHC S-600, SPL, 17 m penetration depth*: Levels are shown along a single transect of azimuth 315°, out to 10 km range, and down to 50 m depth, highlighting the depths of 14 and 23 m.

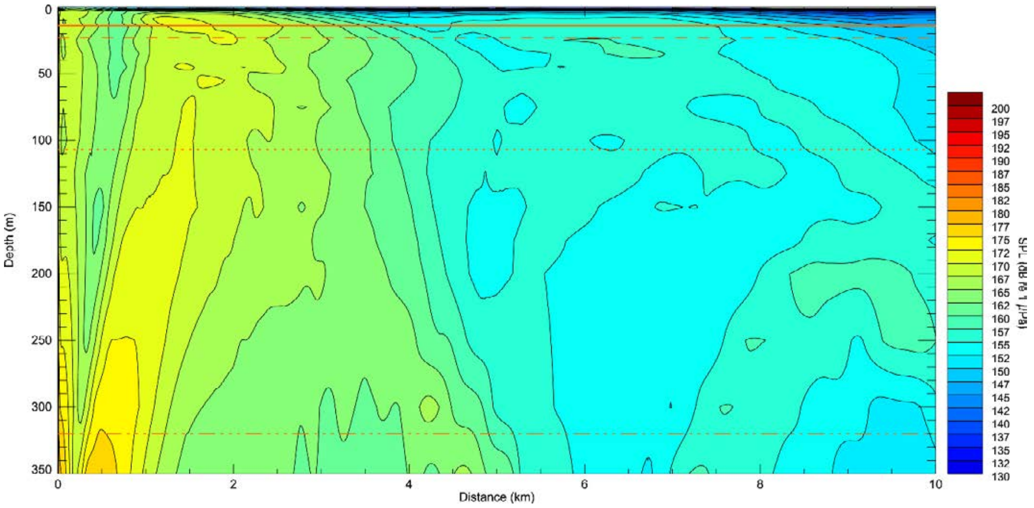

Figure 55. *Brecknock, vertical slice, IHC S-600, SPL, 17 m penetration depth*: Levels are shown along a single transect of azimuth 315°, out to 10 km range, and down to 350 m depth, highlighting the depths of 14, 23, 107 and 320 m.

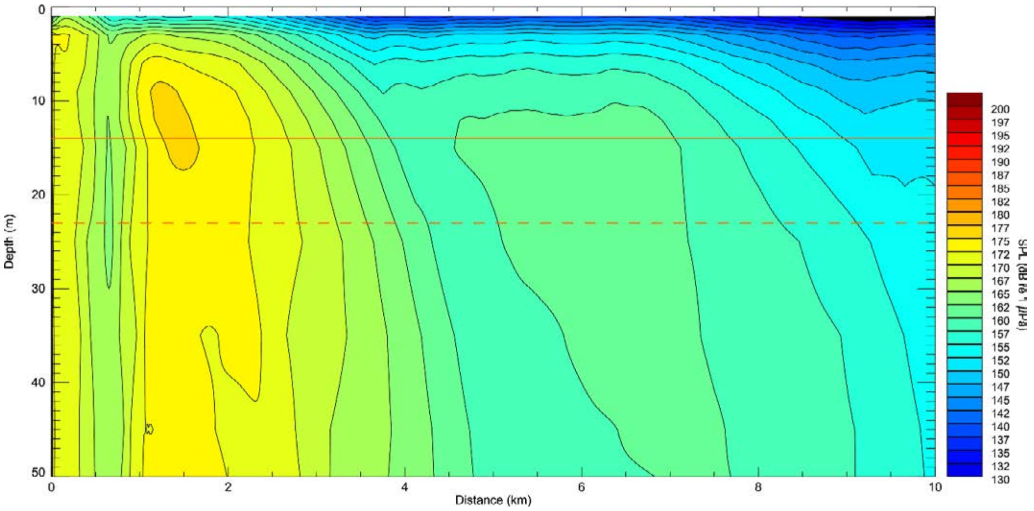

Figure 56. *Brecknock, vertical slice, IHC S-1200, SPL, 17 m penetration depth*: Levels are shown along a single transect of azimuth 315°, out to 10 km range, and down to 50 m depth, highlighting the depths of 14 and 23 m.

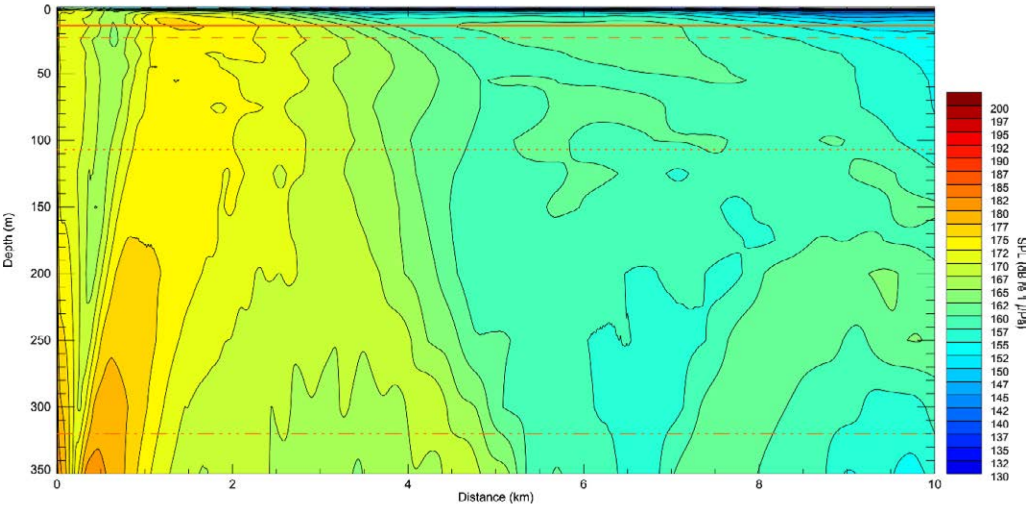

Figure 57. *Brecknock, vertical slice, IHC S-1200, SPL, 17 m penetration depth*: Levels are shown along a single transect of azimuth 315°, out to 10 km range, and down to 350 m depth, highlighting the depths of 14, 23, 107 and 320 m.

4.2.3. Multiple Strike Sound Fields

Table 37 presents the SEL_{24h} results relevant to marine mammals for the proposed pile driving operations, while Table 38 shows modelled distances to the cumulative exposure criteria contours for fish, fish eggs and larvae. The sound level contour maps for cetaceans and turtles are presented in Figures 58 and 59 for the IHC S-600 and the IHC S-1200 hammers, respectively. The sound level contour maps for fish are presented in Figures 60 and 61 for the IHC S-600 and the IHC S-1200 hammers, respectively.

Table 37. *Brecknock piling*: Maximum-over-depth distances (in km) to frequency-weighted SEL_{24h} based marine mammal PTS and TTS thresholds (NMFS 2018) and turtles (Finneran et al. 2017).

4.2.4. Animal Movement and Exposure Modelling

Summaries of the animat modelling results for migrating and foraging pygmy blue whales are provided in Table 39. No exposures were recorded for migratory or inter-nesting turtles due to the distance from the pile of the Woodside defined BIAs.

Table 39. *Brecknock*: Summary of animat simulation results for migratory and foraging pygmy blue whales. Includes the distances to acoustic modelling thresholds (km), the 95th percentile exposure ranges (km), and the number of real-world individuals exposed above threshold (where densities are available). This summary includes both the original animat simulation results and the results excluding animats within a 2000 m zone surrounding the pile, acoustic modelling results are presented in Tables 34, 35, and 37.

Threshold		**Distance to threshold from acoustic modelling**		**Migrating pygmy blue whales**		**Migrating pygmy blue whales with 2000 m exclusion zone**		**Foraging pygmy blue whales**		**Foraging pygmy blue whales with 2000 m exclusion zone**

* R_{max} reported for TTS PK and PTS PK from acoustic modelling

4.3. Vertical Seismic Profiling (VSP)

Per-pulse results for the proposed VSP are presented in this section for maximum-over-depth SPL, SEL, and PK (tables in Section 4.3.1.1), maps and sound field vertical slices (Section 4.3.1.2). Multiple pulse results are presented in Section 4.3.2. Table 40 shows the PK and per-pulse SEL source levels in the horizontal-plane broadside (perpendicular to the array), endfire (in-line with the array), and vertical directions. The vertical source level that accounts for the "surface ghost" (the out of phase reflected pulse from the water surface) is also presented to make it easier to compare the output of other seismic source models.

Table 40. Far-field source level specifications for the 750 in^3 array, for a 6 m operational depth. Source levels are for a point-like acoustic source with equivalent far-field acoustic output in the specified direction. Sound level metrics are per-pulse and unweighted.

Direction	**Peak source pressure level ($L_{S,pk}$) (dB re 1 µPa·m)**	**Per-pulse source SEL ($L_{S,E}$) (dB 1 µPa^{2}m^{2}s)**	
		10–2000 Hz	2000–25000 Hz
Broadside	239.8	214.0	168.7
Endfire	240.1	214.1	175.3
Vertical	239.7	214.0	173.2
Vertical (surface affected source level)	239.7	216.2	176.1

4.3.1. Per-pulse Sound Fields

4.3.1.1. Tabulated results

Per-pulse results for the 750 in³ seismic source operating at 6 m are presented for SPL, SEL, PK, and PK-PK, including seafloor PK and PK-PK. Tables 41–43 list the estimated ranges for the various applicable maximum-over-depth per-pulse effects criteria and isopleths of interest. Table 44 lists the estimated ranges for seafloor per-pulse effects criteria and isopleths of interest.

Table 41. *VSP, per-pulse SEL*: Maximum (R_{max}) and 95% ($R_{95\%}$) horizontal distances (in km) from the 750 in^3 VSP array to modelled maximum-over-depth unweighted isopleths from the two modelled single impulse sites.

4.3.1.2. Sound field maps and graphs

Maps of the per-pulse SPL results for the two VSP locations are shown in Figures 62 and 63. Per-pulse SEL maps are shown in Appendix H.2.

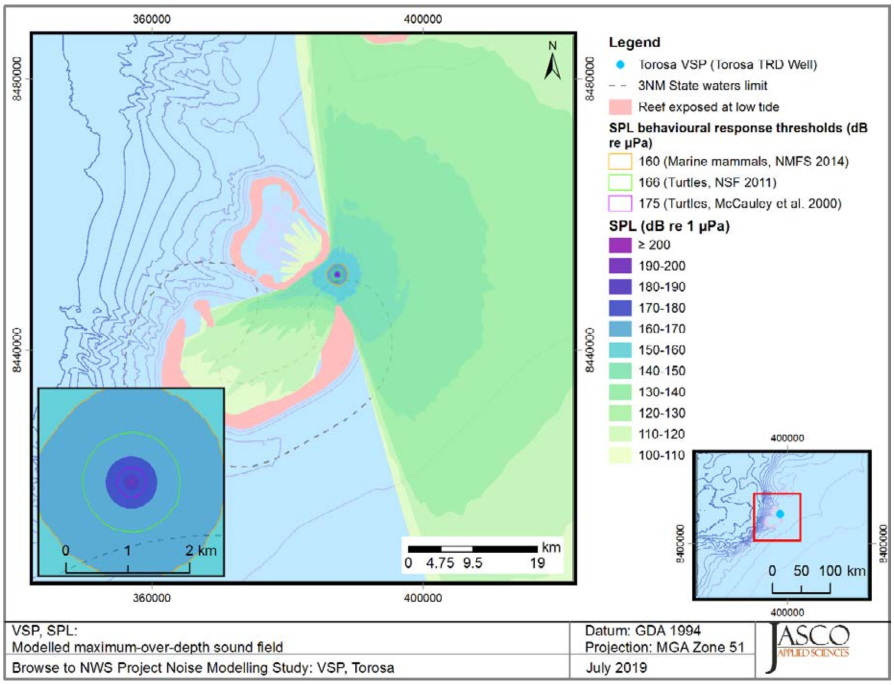

Figure 62. *Torosa TRD Well VSP, SPL:* Sound level contour map, showing maximum-over-depth results. Isopleths for turtles (166 and 175 dB re 1 µPa) and marine mammal (160 dB re 1 µPa) behavioural criteria are shown.

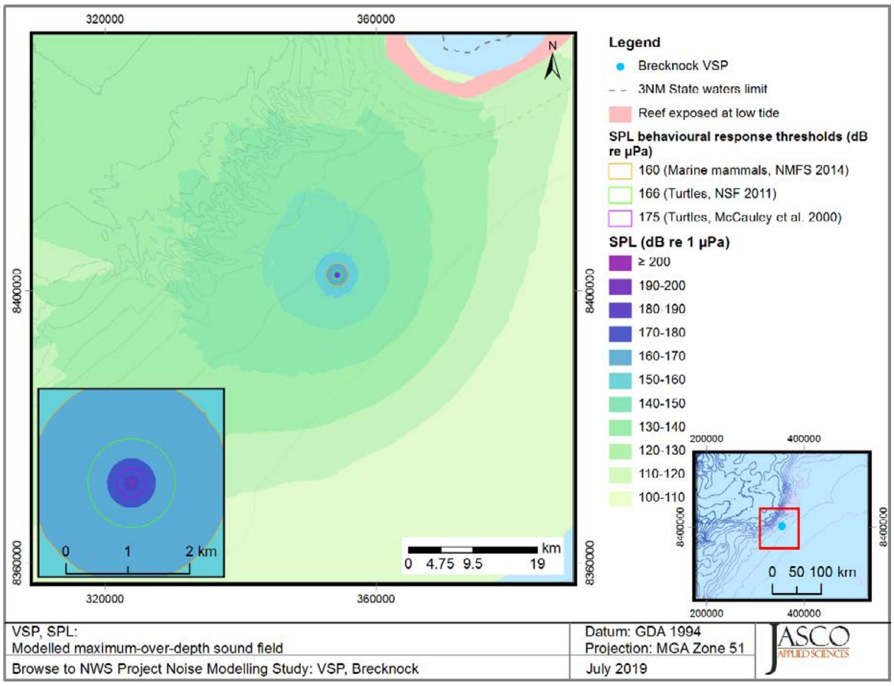

Figure 63. *Brecknock VSP, SPL:* Sound level contour map, showing maximum-over-depth results. Isopleths for turtles (166 and 175 dB re 1 µPa) and marine mammal (160 dB re 1 µPa) behavioural criteria are shown.

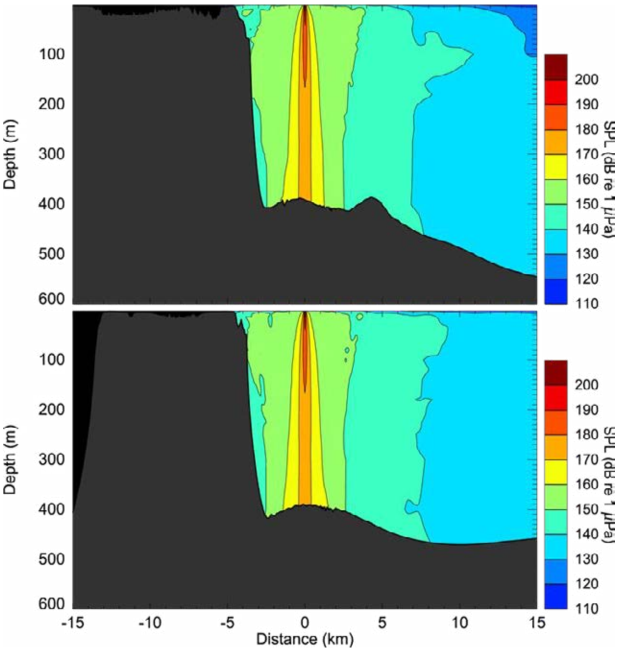

Figure 64. *Vertical slice, Torosa TRD Well VSP, SPL*: north–south (top) and east–west (bottom).

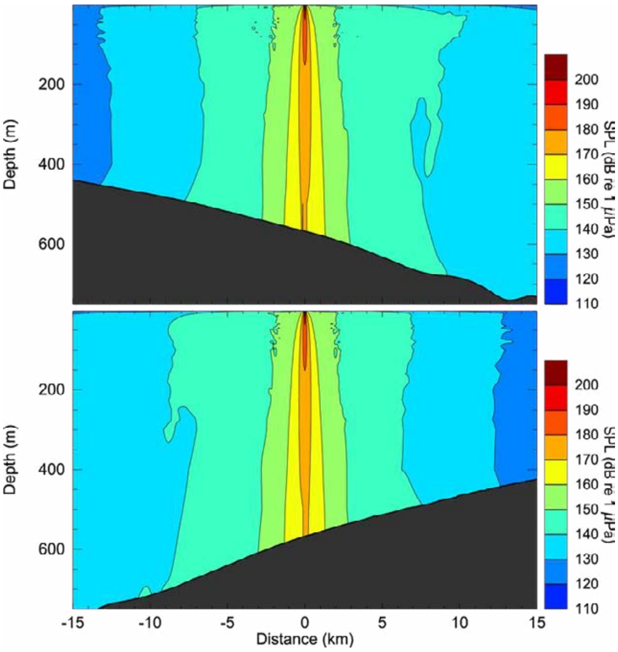

Figure 65. *Vertical slice, Brecknock VSP, SPL*: north–south (top) and east–west (bottom).

Multiple pulse

Multiple pulse results for a range of VSP impulses which potentially could occur within a 24 h period are shown in Tables 45 and 46. These results assume both stationary source and receivers, and are frequency-weighted in accordance with NMFS (2018) and Finneran et al. (2017).

Table 45. Torosa *VSP, multiple-pulse SEL*: Maximum ranges to frequency-weighted SEL_{24h} based marine mammal PTS and TTS thresholds NMFS (2018) and turtles (Finneran et al. 2017) from VSP operations, assuming different numbers of impulses during a 24 h period.

4.4. Vessel noise (MODU, OSV, and FPSO)

Sound field results for the modelling scenarios involving the MODU, OSV and FPSO, both with and without DP and during offtake are presented for SPL (Tables 47–49) and SEL_{24h} (Tables 50 and 51) at Torosa and Brecknock. Areas within relevant threshold isopleths during offtake, including a comparison between individual FPSO's and aggregate FPSO's are presented for SPL and SEL_{24h} metrics in Tables 52–55. Ranges to fish thresholds are unchanged from the individual sources to aggregate scenarios, as the ranges are not greater than the modelling resolution.

4.4.1. Tabulated results

Table 47. *Torosa vessels, SPL*: Maximum (R_{max}) and 95% ($R_{95\%}$) horizontal distances (in km) from the centroid of the modelled thrusters (MODU, OSV, and FPSO on DP) or from the centre of the vessel (FPSO without DP).

4.4.2. Sound Field Maps and Graphs

Maps of the estimated sound fields, threshold contours, and isopleths of interest for SPL and SEL$_{24h}$ sound fields have been presented at both modelling sites for individual locations for vessel modelling scenarios (Table 8) in Figures 66–85, and aggregate modelling scenarios in Figures 86–89.

4.4.2.1. Standalone scenarios

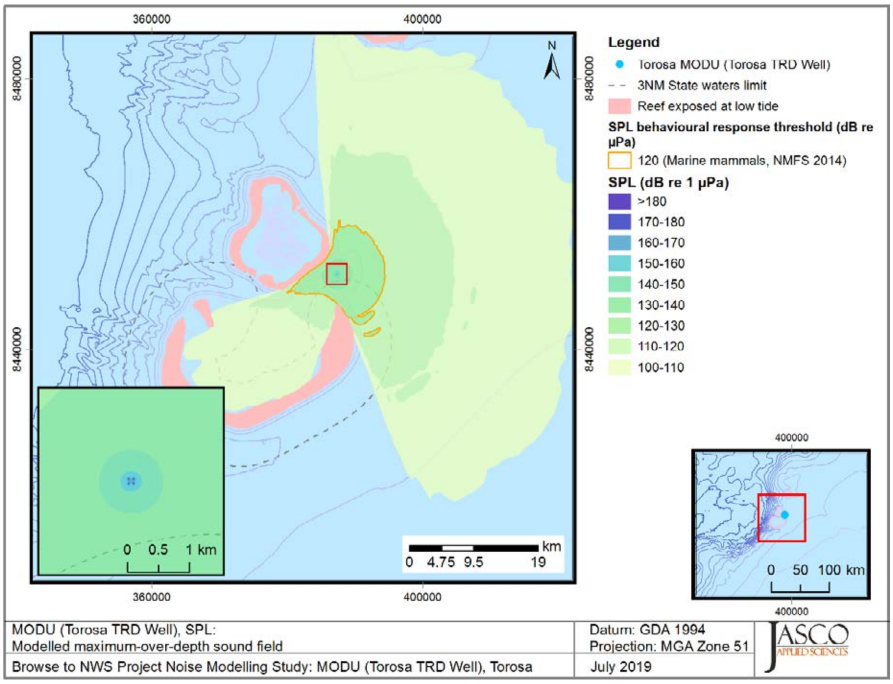

Figure 66. *Torosa, MODU, SPL*: Sound level contour map, showing maximum-over-depth results. Isopleth for marine mammal behavioural criteria (120 dB re 1 µPa) is shown.

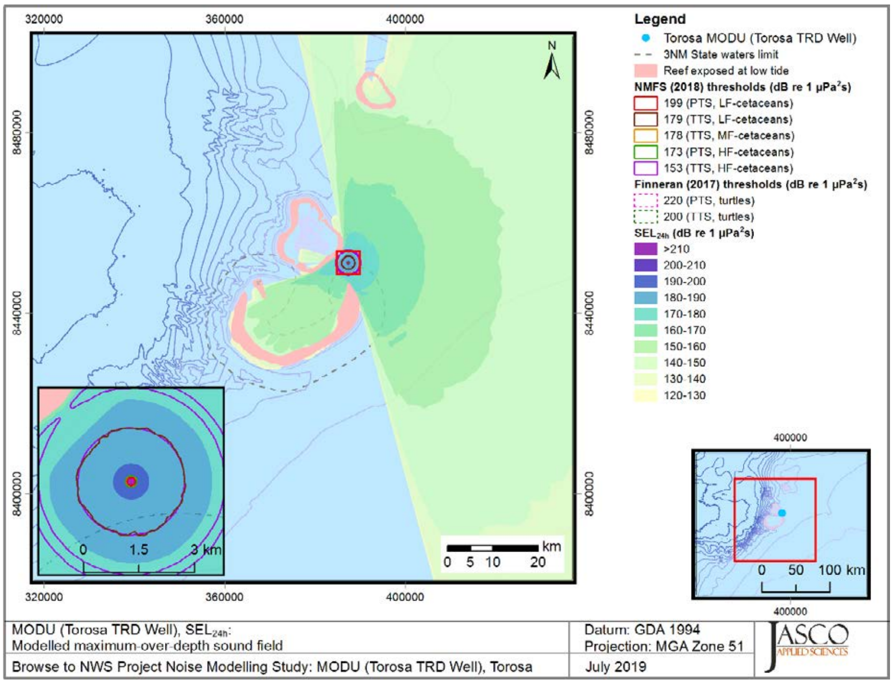

Figure 67. *Torosa, MODU, SEL$_{24h}$*: Sound level contour map showing unweighted maximum-over-depth SEL$_{24h}$ results, along with isopleths for low-, mid-, and high-frequency cetaceans and turtles. Threshold for mid-frequency cetacean PTS was not reached.

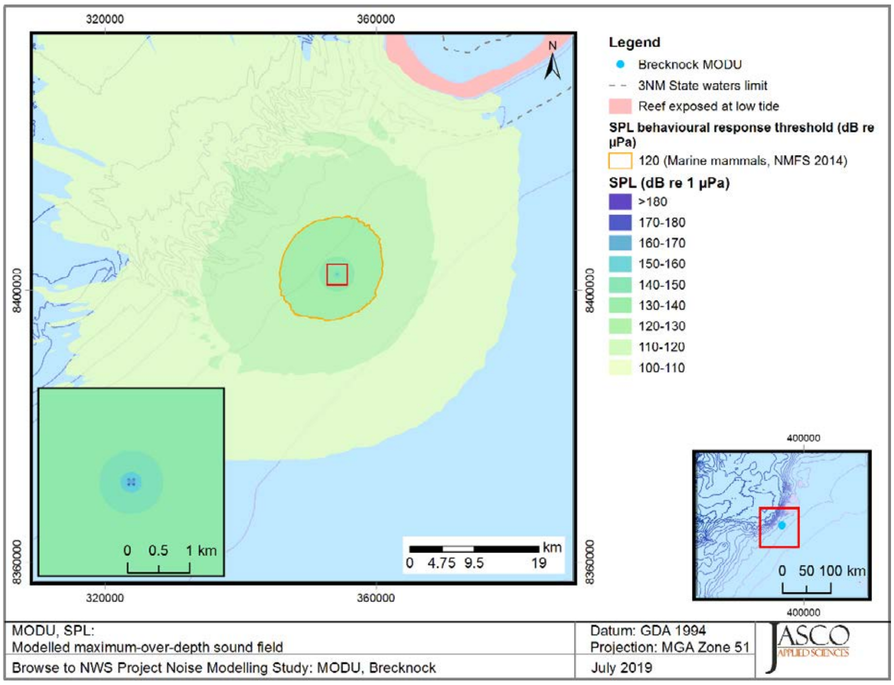

Figure 68. *Brecknock, MODU, SPL*: Sound level contour map, showing maximum-over-depth results. Isopleth for marine mammal behavioural criteria (120 dB re 1 µPa) is shown.

5. Discussion and Summary

5.1. Pile Driving

5.1.1. Acoustic propagation

This study predicted underwater sound levels associated with impact driving of subsea piles to anchor the Torosa FPSO facility turret. The underwater sound field was modelled for 53.25 m long piles with a 5.5 m diameter with 60 mm wall thickness; The piles will be driven a total of 51.5 m into the seabed. The modelling applied a sound speed profile derived from a public database (Appendix F.3.2), and also accounted for bathymetric variations (Appendix F.3.1) and local geoacoustic properties (Appendix F.3.3). The broadband sound energy at 10 m for each penetration depth ranged from 184.6–199.4 dB re 1 μPa^2·s with the peak sound energy concentrated in the frequency range 70 to 300 Hz (Figure 16), with levels from the pile at the 17 m penetration depth having the highest energy.

Noise emissions from pile driving were considered here to be cylindrically isotropic (i.e., omnidirectional in the horizontal plane). As such, variations in noise that propagates across azimuths are attributed to the bathymetry alone, with this accounted for in the modelling methodology. When the hammer strikes the pile, noise propagates into the water as a downward Mach cone (see Appendix B). A portion of the energy from the strike is also reflected at the pile bottom, generating an upward Mach cone. This cycle of downward propagation, reflection, and upward propagation occurs multiple times per strike. At close range from the pile, noise levels are determined by the summation of Mach cones, which might add constructively (i.e., their summation results in a total wave with higher amplitude than the original ones) or destructively (i.e., wavefronts can cancel each other, resulting in low amplitudes). The way in which Mach cones combine with each other is strongly dependent on their frequency content, which is determined by the hammer forcing function and the pile dimensions.

Due to the relation between the speed of sound in steel (~5000 m/s) relative to the speed of sound in the water (~1490 m/s at the depth of the pile), the Mach cone propagates away from the pile and impinges the seabed at an angle of ~17°. The first bottom bounce occurs within 16 m from the pile, and the first surface bounce occurs within 1.5 from the pile. As shown in Figure 25, the Mach cone corresponding to the shallowest pile penetration introduces substantial energy that propagates through the water column, compared to the 45 m pile penetration scenario in Figure 27, for which underground sound propagation tends to dominate near the pile.

The modelling of the three penetration depths for each pile provides a detailed quantification of the associated sound levels for each penetration. The distances to all per-strike isopleths are farthest at the start of piling when most of the pile is in the water column, and distances are shortest at the end of piling when most of the pile is buried in the sediment. This is despite the per-strike pile penetration being less during the final stages of driving, and the increased resistance generating stronger stress-wave reflections at the pile toe. Therefore, the amount of pile in the water has greatest influence on the in-water sound levels. The isopleths for unweighted marine mammal behavioural thresholds for each penetration are presented on the same map for each hammer to assist with comparison (Figures 23 and 24 for Torosa and Figures 46 and 47 for Brecknock). The highest peak pressure levels are predicted to occur at the shallowest penetration (17 m) and for the IHC S-1200.

5.1.1.1. Propagation at Torosa

As evidenced in Figures 23 and 24, sound propagation around the pile is mostly isotropic, except along transects toward the North Scott Reef in the eastern direction. Along these transects, the following phenomena take place:

- Sound is significantly blocked when it reaches the exposed reefs, as the acoustic wavefront hits the limestone interface and reflects. This is due to the high impedance contrast between water and limestone. Note that the results presented here do not account for backpropagated sound.
- At azimuth 240˚ from the pile, sound propagates within the channel between the two reefs as far as the bathymetry allows (see Figures 25–30). Between 3–17 km from the pile, propagation takes place along a sand/gravel seabed, which enhances energy contributions from seabed reflections

in this direction (compared to those in directions away from the reef). At a range of approximately 17 km from the pile, the bathymetry abruptly reduces from ~440 m depth to 50 m depth.

- Beyond 17 km range from the pile, sound propagates along a shallow (50 m depth) waveguide, up to 30 km, where it reaches the shallow reef and sound is blocked. At ranges >17 km, despite bottom reflections being strong (due to the high acoustic contrast between water and limestone), sound propagation is not significant, as very small amount of energy enters the shallow waveguide (see Figures 25–30).

The enhanced propagation along sandy/gravel seabed is observed as "sound islands" in maps of SPL and SEL_{24h} criteria. The R_{max} radius is more representative of the effective extent of the footprint because the source is stationary and is more conservative, however, when determining potential impacts, the azimuthal distribution of sound should be considered, particularly at Torosa. Given the likely soil resistance, the modelling scenarios represent the maximum noise footprint from pile driving activities as a conservative estimate.

The maximum received level at the Scott Reef state waters limit (Table 9) is 160.8 or 165.2 dB re 1 µPa, depending upon the hammer used (Table 26).

5.1.1.2. Propagation at Brecknock

For Brecknock, sound interaction with the reefs only takes place at ranges of at least 30 km from the pile (in the northeast direction). Therefore, the different seabed types around the reefs have no influence on distances to the thresholds presented in this study (which when reached, occur at shorter ranges). At this location, sound propagation is mostly affected by bathymetry features. At ranges less than 13 km from the pile, the bathymetry varies smoothly from 400 m to 800 m from southeast–northwest direction. This smooth variation has little impact on sound propagation, resulting in mostly isotropic sound propagation (i.e. Figures 46 and 47). Beyond 13 km range from the pile, transects northwest from the pile encounter slightly rougher bathymetry features and steeper bathymetry decay, reaching water depths as deep as ~2.4 km 80 km from the pile. Contrary to this, transects southeast from the pile encounter a sharp decrease in water depth at ranges 50 km–60 km, reaching water depths ~100 m at 80 km from the pile. The influence of this asymmetry on sound propagation can be observed in the sound field maps in Section 4.2.2.2, for which sound propagates farther along downslope bathymetry lines.

5.1.2. Ranges to exposure thresholds

For criteria based on SEL_{24h} metrics, the ranges must be considered in context of the duration of operations. For the purposes of modelling, one pile will be driven per day; therefore, the corresponding sound level is denoted as SEL_{24h}; however, the estimated times for driving piles are 78.5 or 45.5 minutes (Torosa) and 80.1 or 47.4 minutes (Brecknock) for medium and high-power hammers, respectively (Table 16 for Torosa and Table 17 for Brecknock). SEL_{24h} is a cumulative metric that reflects the dosimetric impact of noise levels within the driving period, assuming that an animal is consistently exposed to such noise levels at a fixed position. The radii that correspond to SEL_{24h} typically represent an unlikely worst-case scenario for SEL-based exposure because, more realistically, marine fauna (mammals or fish) would not stay in the same location or at the same distance from a sound source for an extended period. Therefore, a reported radius for SEL_{24h} criteria does not mean that any animal travelling within this radius from the source *will* be exposed to PTS or TTS, but rather that it *could* be exposed if it remained within that range for the entire duration of the pile driving

For each sound level threshold, the maximum range (R_{max}) and the 95% range ($R_{95\%}$) were calculated. R_{max} is the distance to the farthest occurrence of the threshold level, at any depth. $R_{95\%}$ for a sound level is the radius of a circle, centred on the source, encompassing 95% of the sound at levels above threshold. Using $R_{95\%}$ reduces the sensitivity to extreme outlying values (the farthest 5% of ranges).

5.1.2.1. Marine mammals

The results for the NMFS (2018) criteria applied for marine mammal PTS and TTS consider both metrics within the criteria (PK and SEL), with SEL assessed here for a single pile within a 24 h period, i.e., a single pile per day. The metric with the longest distance must be applied, and these maximum distances along with the relevant metric are summarised in Table 56.

The maximum distances to the NMFS (2014) marine mammal behavioural response criterion of 160 dB re 1 µPa (SPL) are associated with the shallowest penetration of 17 m for both hammers, with the maximum distances summarised in Table 57.

Table 56. *Marine mammal injury and hearing sensitivity changes*: Maximum-over-depth distances (in km) from the pile to PTS and TTS thresholds (NMFS 2018). PK results are in Table 24 for Torosa and Table 35 for Brecknock and results for SEL$_{24h}$ are in Table 27 for Torosa and Table 37 for Brecknock.

5.1.2.2. Turtles

The results for the Finneran et al. (2017) criteria applied for turtle PTS and TTS consider both metrics within the criteria (PK and SEL), with SEL assessed here for a single pile within a 24 h period, i.e., a single pile per day. The metric with the longest distance must be applied, and these maximum distances along with the relevant metric are summarised in Table 58.

The maximum distances to the two criteria considered, the NMFS criterion for behavioural response (SPL of 166 dB re 1 µPa) and a criterion for behavioural disturbance (SPL of 175 dB re 1 µPa)

(McCauley et al. 2000a, 2000b), are associated with the shallowest penetration of 17 m for both hammers, with the maximum distances summarised in Table 59.

Table 58. *Turtle injury and hearing sensitivity changes*: Maximum-over-depth distances (in km) to PTS and TTS thresholds from Finneran et al. (2017). PK results are in Table 24 for Torosa and Table 35 for Brecknock. Results for SEL_{24h} are in Table 27 for Torosa and Table 37 for Brecknock.

‡ Threshold for turtle behavioural response to impulsive noise (NSF 2011).

5.1.2.3. Fish, fish eggs, and fish larvae

The modelling study assessed the ranges for quantitative criteria from Popper et al. (2014) associated with mortality and potential mortal injury and impairment in the following:

- Fish without a swim bladder (also appropriate for sharks in the absence of other information)
- Fish with a swim bladder not used for hearing
- Fish that use their swim bladders for hearing
- Fish eggs, and fish larvae

Considering both per-strike modelled penetrations and associated SEL_{24h} scenario, along with both PK and SEL_{24h} metrics, in line with the conditions of the criteria, the maximum distances are summarised in Table 60 for Torosa and Table 61 for Brecknock.

Table 60. *Torosa fish effect thresholds:* Summary of maximum fish, fish eggs, and larvae injury and TTS onset distances for single impulse and SEL_{24h} modelled scenarios (PK values from Table 25, SEL_{24h} values from Table 28).

5.2. Animal movement and exposure modelling

The estimated sound fields produced by source and propagation models for the driving of a single pile were incorporated into the JASMINE sound exposure model to estimate the number of animals potentially exposed to levels above the defined thresholds. The range within which 95% of the exposure exceedances occur was also reported (95th percentile ranges, P_{95}, which could also be referred to as Exposure Range 95%, or $ER_{95\%}$). No density data were available for migratory green turtles (Section 3.7.3.2) therefore results are presented in terms of the 95th percentile ranges only. Mitigation of potential impacts through exclusion zones for turtles and pygmy blue whales (500 and 2000 m, respectively) were considered in the modelling.

5.2.1. Torosa FPSO anchor piles

Animal movement modelling simulation results predict that inter-nesting turtles are unlikely to be exposed above TTS, PTS, or behavioural thresholds for either of the two hammers at the Torosa location. Real-world densities are unavailable for migrating green turtles, so the true number of animals are not calculated in that case. However, there were no PTS PK, PTS SEL_{24h}, or TTS PK exposures above threshold for either hammer. Prior to considering exclusion zones, the 95th percentile range to TTS SEL_{24h} was 1.65 km and 1.79 km for the S-600 and S-1200 hammers, respectively. After considering a 500 m exclusion zone, the number of animals impacted was reduced by 20.7% for the S-600 hammer and 11.5% for the S-1200 hammer.

A number of migrating green turtles were exposed above both behavioural thresholds. The 95th percentile range to animats exceeding the behavioural disturbance threshold (175 dB re 1 µPa) was 50 m for the S-600 hammer and 1.77 km for the S-1200 hammer. Whilst the range to animats exceeding the behavioural response threshold (166 dB re 1 µPa) was 2.54 or 4.64 km for the S-600 or S-1200 hammer. The effectiveness of the exclusion zone in reducing exposures was moderate (less than 11%) in most cases. The exception being the exposures over the behavioural disturbance threshold for the S-600 hammer, in which the application of the exclusion zone reduced the number of animats exposed above threshold by 100%, or to zero.

Without considering the 2000 m exclusion zone, neither the migrating nor foraging pygmy blue whales are expected to be exposed above TTS PK or PTS PK thresholds for either of the two hammers. Regardless of hammer type, a total of 0.02 migrating pygmy blue whales are expected to be exposed above the PTS SEL_{24h} threshold, and a total of 0.06 foraging pygmy blue whales are expected to be exposed above the PTS SEL_{24h} threshold. The number of animats exposed above TTS SEL_{24h} was similar for between hammer types for migrating blue whales, with 1.28 or 1.30 individuals exposed for the S-600 and S-1200 hammer, respectively. The number of individual foraging blue whales exposed above TTS SEL_{24h} was slightly higher, but also similar between the two hammers, with 1.65 and 1.75 individuals for the S-600 and S-1200 hammers. After applying the 2000 m exclusion zone, the number of pygmy blue whales exposed above PTS SEL_{24h} threshold dropped to zero for both hammers.

The number of animals expected to be exposed above the 160 dB re 1 µPa (SPL) behavioural threshold ranges ranged from 0.58 for the foraging pygmy blue whale with the S-600 hammer, to 1.41 for the migrating pygmy blue whale with the S-1200 hammer.

For the thresholds which occur at a greater distance from the pile (TTS SEL_{24h}, and behavioural thresholds), more animats for both species and both hammers were exposed above threshold at larger ranges. Consequently, the effect of the exclusion zone wasn't significant for those metrics. Most of the ranges computed after the application of exclusion zones either increased or stayed the same, due to the influence on the statistical distribution of exposure ranges. In the cases where the exclusion zone encompassed all the exposures above threshold, there were no exposures remaining and the 95th percentile range therefore dropped to zero. Figure 90 shows the distribution of 95th percentile ranges before and after the application of the 2000 m exclusion zone for migrating pygmy blue whales above the behavioural threshold. After applying the exclusion zone, all of the close-range exposures were removed, which effectively shifted the entire distribution to longer ranges. This shift is reflected in the 0.58 km increase in 95th percentile range. Figure 91 shows the case where all the exposures above threshold occur within the exclusion zone range. Once the exposures below that range are excluded, the 95th percentile range defaults to zero.

The migratory behavioural profile includes migratory dives with a mean depth of 14 m ± 4 m (24 m maximum), and exploratory dives with a mean maximum depth of 107 ± 81 m (320 m maximum) (Section 3.7.2.1). These are included in the behavioural profile (Table G-2) as gaussian distributions. Due to the low sample size (a single animal), the variability across the population is unknown. To provide context if the distribution centres (means) are different, focused slice plots were produced (Figures 31–34). Within one standard deviation for the migratory dives, 4 m, there is minimal difference between the sound field distribution within the water column, and only a slight difference between the mean and maximum. For the exploratory dives, the levels are louder shallower than the mean or deeper than the mean depending upon the distance from the source. However, as the whales are moving up and down within the water column during their dives, they are exposed to a range of sound levels, including the quieter levels close to the surface.

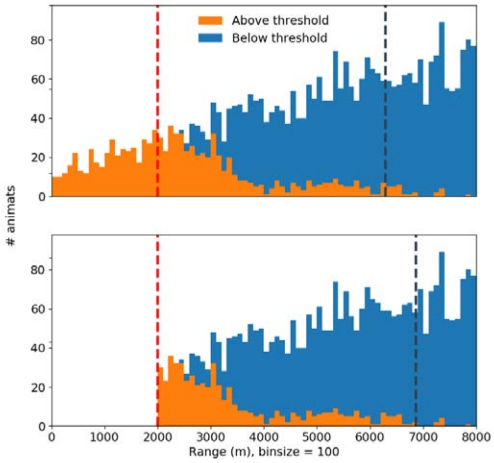

Figure 90. *Pygmy blue whale behavioural threshold*: Histograms of the distribution ranges for pygmy blue whale animat exposures for the S-600 hammer, showing (upper panel) exposures without and (lower panel) with an exclusion zone. Black dashed line: 95th percentile ranges. Red dashed line: 2000 m exclusion zone boundary.

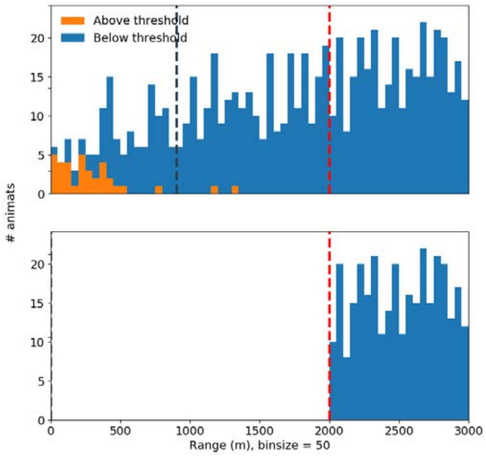

Figure 91. *Pygmy blue whale PTS threshold*: Histograms of the distribution ranges for pygmy blue whale animat exposures for the S-600 hammer, showing (upper panel) exposures without and (lower panel) with an exclusion zone. Black dashed line: 95th percentile ranges. Red dashed line: 2000 m exclusion zone boundary.

Implementing an exclusion zone of 500 m for green turtles and 2000 m for pygmy blue whales reduced all exposures above TTS and PTS threshold criteria to zero for both hammers, except for the TTS SEL_{24h} thresholds, where estimated exposures were only slightly reduced.

Interpretation of the 95th percentile ranges is nuanced and is the result of specific acoustic propagation characteristics as well as the probabilistic nature of the animal movement modelling simulation. As an example, Figure 92 shows vertical slices of SPL as a function of range and depth in the upper water column at a single azimuth (270°) for all three penetration depths for the IHC S-1200 hammer. The histograms in Figure 93 show how the probability of migrating green turtle exposures above threshold within the 95th percentile range varies as a function of the specific exposure threshold being applied (either 166 or 175 dB re 1 µPa in this case). A lower threshold level means that turtle animats further from the source will reach that threshold, therefore the computed 95th percentile range of all exposed turtle animats will be larger. Depending on the nature of the sound field as a function of range and depth, larger ranges may encompass different numbers of animats that are above and below sound threshold levels.

The example in Figure 93 demonstrates a case where, due to the nature of the acoustic propagation in the area, a lower proportion of the turtle animats within the higher threshold range are exposed above that threshold. For the S-1200 hammer, 45% of turtle animats within 4.64 km are exposed above the 166 dB SPL behavioural response threshold. For the same hammer, 58% of turtle animats within 1.77 km are above the 175 dB SPL increased behavioural disturbance threshold.

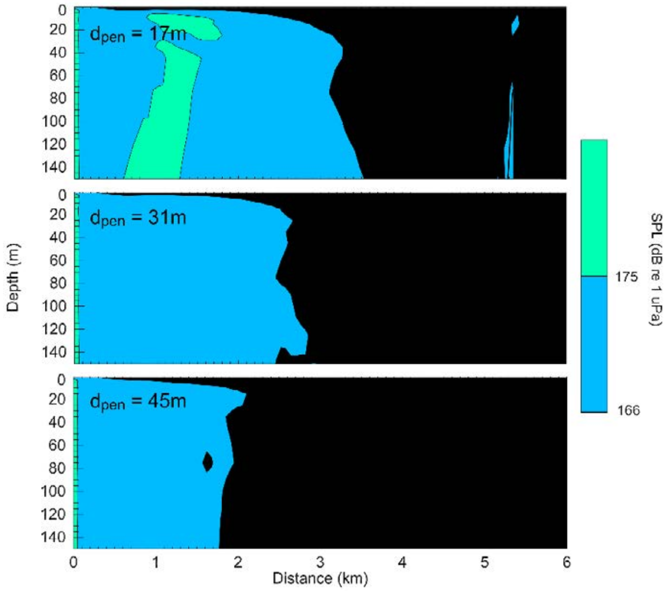

Figure 92. SPL (dB re 1µPa) for each of the modelled pile penetration depths (d_{pen}) as a function of distance from the piling location and depth in the upper 150 m of the water column for the IHC S-1200 hammer. Profiles are at an azimuth of 270°. Specific contours show the behavioural thresholds for green turtles.

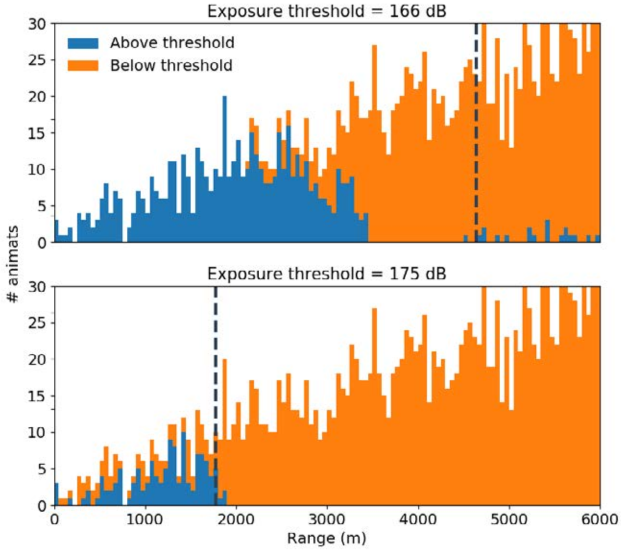

Figure 93. *Turtle behavioural threshold*: Histograms of the distribution ranges migrating green turtle animat exposures for the S-1200 hammer, showing (upper panel) exposures without and (lower panel) with an exclusion zone. Black dashed line: 95th percentile ranges. Red dashed line: 2000 m exclusion zone boundary.

5.2.2. Brecknock FPSO anchor piles

Animal movement modelling simulation results showed that green turtles were not exposed above threshold for PTS, TTS, or behaviour thresholds, even without applying the exclusion zone. This is because the Brecknock pile location is more than 40 km from either the modified inter-nesting or migration area BIAs.

Without consideration of the exclusion zone, pygmy blue whales have no exposures above PTS PK or TTS PK for either hammer. There were 0.02 exposures above PTS SEL_{24h} for the S-600 hammer, and 0.04 exposures above PTS SEL_{24h} for the S-1200 hammer. TTS SEL_{24h} exposures for migrating blue whales ranged from 1.56–1.67 for the S-600 and S-1200 hammers. The number of expected exposures above TTS_{24h} threshold for foraging pygmy blue whales was much lower since the Brecknock piling location is 10.3 km from the BIA: 0.02 individuals for the S-600 hammer and 0.08 individuals for the S-1200 hammer.

With the exclusion zone in place, the PTS SEL_{24h} exposures reduced to zero. The number of predicted exposures for foraging pygmy blue whales did not change as a result of applying an exclusion zone because of the large distance to the BIA.

The distribution of sound within the water column at depths relevant to the migratory behavioural profile, shown in Figures 58–61, follows a similar trend to that observed at Torosa, although the sound fields are quieter at greater ranges. Changes to migratory dive behaviour that result in a mean dive depth of a few metres deeper or shallower are, based on the presented results, unlikely to change the exposure ranges significantly.

5.3. VSP

5.3.1. Acoustic propagation

This study predicted underwater sound levels associated with VSP sources at Torosa TRD Well and Brecknock. The underwater sound field was modelled for a 750 in^3 seismic source array deployed at depth 6 m (Appendix C). Since the VSP source is mostly isotropic (vertically and horizontally), sound propagation for this source is driven by bathymetry features. For the Brecknock location, sound propagates larger distances towards the northwest, along downslope bathymetries. Similarly, for the Torosa TRD Well location sound from the VSP propagates mostly towards the north, passing along the west side of North Scott Reef. At both locations, sound is effectively blocked by the shallow reefs, which is more evident at the Torosa location due to its close proximity to the VSP source.

The overall broadband (10–25000 Hz) unweighted per-pulse SEL source level was 214.0 dB 1 μPa^2m^2s and 214.1 dB 1 μPa^2m^2s in the broadside and endfire directions, respectively. Additional results are presented in Table 40.

5.3.2. Ranges to exposure thresholds

The findings for the VSP operations pertaining each of the metrics and criteria for various marine species of interest are summarised below.

Marine mammals

- The maximum distance where the NMFS (2014) marine mammal behavioural response criterion of 160 dB re 1 µPa (SPL) could be exceeded varied between 1.6 and 1.7 km, provided in Table 42, with the distance being longer at Brecknock.
- The results for the criteria applied for marine mammal Permanent Threshold Shift (PTS), NMFS (2018), consider both metrics within the criteria (PK and SEL_{24h}), with results presented in Tables 43, 45 and 46.. The SEL_{24h} considers a range of impulses within 24 h, from 1 to 150. The applicable metric from the criteria, associated with the longest distance associated with either metric, depends upon the number of impulses with the 24 h. The ranges presented are based upon no more than 150 impulses within 24 h. A reported radius for SEL_{24h} criteria does not mean that marine mammals travelling within this radius of the source will be impacted, but rather that an

animal could be exposed to the sound level associated with auditory impairment (either PTS or TTS) if it remained in that location for either the duration of the activity or 24 hours.

PTS and TTS are not predicted to occur in mid-frequency cetaceans. For PTS in high-frequency cetaceans, the PK metric is always associated with the longest range (68 m), while for PTS in low-frequency cetaceans, for less than 10 impulses the range is greater due to the PK metric (12 m), but otherwise the range is determined by SEL_{24h}, with the maximum distance of 200 m being associated with 150 impulses at either Torosa TRD Well or Brecknock.

For TTS in high-frequency cetaceans the PK metric is always associated with the longest range (141 m), while for TTS in low-frequency cetaceans the range is determined by SEL_{24h}, with the maximum distance of 1 1.69 km for 150 impulses at Torosa TRD Well or Brecknock.

Turtles

- The VSP source is not predicted to cause PTS in turtles, as it doesn't cause either the PK or SEL_{24h} criteria from Finneran et al. (2017) to be exceeded at a distance greater than the horizontal modelling resolution (20 m) from the source (Tables 43 and 45).

  As with marine mammals, the SEL_{24h} considers a range of impulses within 24 h, from 1 to 150. While the TTS criteria due to the PK metric isn't exceeded, depending upon the number of impulses, the TTS SEL_{24h} criteria can be exceeded at up to 160 m for 150 impulses at Torosa TRD Well or Brecknock.
- Similarly to marine mammals, a reported radius for SEL_{24h} criteria does not mean that turtles travelling within this radius of the source will be impacted, but rather that an animal could be exposed to the sound level associated with auditory impairment (TTS) if it remained in that location for either the duration of the activity or 24 hours.
- The distances at where the two criteria considered in relation to turtle behaviour, behavioural response and disturbance, could be exceeded are summarised in Table 62.

Table 62. Distances to turtle behavioural response criteria (from Table 42).

SPL (L_p; **dB re 1 µPa**)	**Distance**	
	R_{max} (km)	$R_{95\%}$ (km)
Torosa TRD Well		
175†	0.23	0.23
166‡	0.81	0.77
Brecknock		
175†	0.23	0.23
166‡	0.72	0.69

† Threshold for turtle behavioural response to impulsive noise (McCauley et al. 2000a, McCauley et al. 2000b).
‡ Threshold for turtle behavioural response to impulsive noise (NSF 2011).

Fish, fish eggs, and fish larvae

- This modelling study assessed the ranges for quantitative criteria based on Popper et al. (2014) and considered both PK (seafloor and water column) and SEL_{24h} metrics associated with mortality and potential mortal injury and impairment (as defined in the criteria) in the following groups:
  - Fish without a swim bladder (also appropriate for sharks in the absence of other information)
  - Fish with a swim bladder that do not use it for hearing
  - Fish that use their swim bladders for hearing
  - Fish eggs and fish larvae
- Sound levels at the seafloor do not exceed any of the criteria.

- Based on PK metrics, acoustic injury could be sustained within a maximum horizontal distance of 21 m of the source for fish without a swim bladder, and within a maximum horizontal distance of 40 m for fish with a swim bladder, fish eggs, and fish larvae (Table 43). SEL_{24h} metrics for injury were not exceeded.

Sponges and Coral

- To assist with assessing the potential effects on sponges and coral receptors, the PK sound level at the seafloor directly underneath the VSP source was estimated at both modelling sites. It was found that the sound level of 226 dB re 1 µPa PK, a sound level associated with no effect (Heyward et al. 2018) was not reached.

5.4. Vessel Noise (MODU, OSV, and FPSO)

5.4.1. Acoustic propagation

This study predicted underwater sound levels associated with the operations of a Mobile Offshore Drilling Unit (MODU), FPSOs with and without DP operating, an OSV near each FPSO, and Offtake operations including an FPSO under DP, a noiseless condensate tanker and an OSV for locations at Torosa and Brecknock (Section 3.6). This includes aggregate scenarios which include FPSOs under normal operating conditions (without DP), as well as offtake operations, at both locations simultaneously.

Despite the different vessels having different source depths and either no thrusters or different thruster locations, sound propagation for these sources is driven by bathymetry features. The Torosa TRD Well location, where the MODU is located, is closer to the reef than the FPSO location, and thus the reef has an increased influence on the sound field. Sound propagates into South Scott Reef Lagoon, but the higher levels are restricted to the channel. The SPL sound field for sources located at Torosa (FPSO and OSV) above 120 dB are less influenced by the reef, although they are slightly attenuated in the direction of the reef for considering the FPSO under DP.

For the Brecknock location, sound propagates larger distances towards the northwest, along downslope bathymetries, with the influence apparent for all modelled sources.

Due to the distance of ~70 km between the Torosa and the Brecknock sites, as well as the blockage in line-of-sight due to the reef, contours for the criteria thresholds considered in this study do not combine between sites. Therefore, radii to criteria thresholds presented for FPSOs under normal operating conditions (without DP) and for offtake operations are still valid even in the case of simultaneous activity at Torosa and Brecknock. The only isopleths affected by simultaneous activities at both locations are those corresponding to the lower levels, below either 110 dB re 1 µPa or 170 dB re 1 $\mu Pa^2 \cdot s$ (unweighted) (Figures 87–89), which are not associated to any criteria.

5.4.2. Ranges to exposure thresholds

Marine mammals

The results for the NMFS (2018) criteria applied for marine mammal PTS and TTS for vessels are assessed here for a 24 h period. The maximum distances to PTS are summarised in Table 63, with complete results for PTS and TTS at the Torosa and Brecknock locations presented in Tables 50 and 51. The maximum distances to the NMFS (2014) marine mammal behavioural response criterion of 120 dB re 1 µPa (SPL) are summarised in Table 64, with complete results presented in Tables 47 and 48.

For aggregate scenarios considering both FPSO’s, it was found that due to the separation between the sites, distances to PTS, TTS, and behavioural thresholds remained unaltered compared to the individual operations (Tables 52–55). This was quantified by verifying that the total aggregate area within threshold isopleth for marine mammal behavioural response to continuous noise (NMFS 2014) equals the sum of the areas for the individual operations.

Table 63. *Marine mammal injury*: Maximum (R_{max}) horizontal distances (km) to modelled maximum-over-depth PTS threshold from NMFS (2018) for vessel-based scenarios.

Hearing group	Threshold for PTS, SEL_{24h} (dB re 1 µPa²·s) #	Distance R_{max} (km)				
		MODU	OSV	FPSO on DP	FPSO without DP	FPSO offtake
Torosa						
LF cetaceans	199	0.11	0.05	0.12	-	0.12
MF cetaceans	198	-	-	<0.02	-	<0.02
HF cetaceans	173	0.15	0.07	0.28	-	0.28
Brecknock						
LF cetaceans	199	0.11	0.06	0.12	<0.02	0.12
MF cetaceans	198	-	-	<0.02	-	<0.02

Frequency weighted.
A dash indicates the level was not reached.
FPSO offtake includes an FPSO under DP, a noiseless condensate tanker and an OSV.

Table 64. *Marine mammal behaviour*: Summary of maximum behavioural disturbance distances for vessel-based scenarios, derived from Tables 47 and 48.

SPL (L_p; dB re 1 µPa)	Distance R_{max} (km)				
	MODU	OSV	FPSO on DP	FPSO without DP	FPSO Offtake
Torosa					
120†	10.50	2.25	8.77	0.57	8.89
Brecknock					
120†	8.84	2.39	8.78	0.54	8.89

† Threshold for marine mammal behavioural response to continuous noise (NMFS 2014).
FPSO offtake includes an FPSO under DP, a noiseless condensate tanker and an OSV.

Turtles

Results for the Finneran et al. (2017) criteria applied for turtle PTS and TTS for vessels are assessed here for a 24 h period. The maximum distances to PTS are summarised in Table 65, with complete results for PTS and TTS at the Torosa and Brecknock locations presented in Tables 50 and 51.

Table 65. *Turtle SEL_{24h} thresholds*: Maximum-over-depth distances (in km) to turtle PTS threshold (Finneran et al. 2017).

SEL_{24h} ($L_{E,24h}$; dB re 1 µPa²·s)	Distance R_{max} (km)				
	MODU	OSV	FPSO on DP	FPSO without DP	FPSO Offtake
Torosa					
220†	0.06	0.06	<0.02	-	<0.02
Brecknock					
220†	0.06	0.06	<0.02	-	<0.02

† Threshold for turtle-weighted SEL_{24h} (Finneran et al. 2017).
A dash indicates the level was not reached.
FPSO offtake includes an FPSO under DP, a noiseless condensate tanker and an OSV.

Fish

Sound produced by the vessel operations could cause physiological effects, and recoverable injury, to some fish species, but only if the animals are in very close proximity to the sound sources–within a planar distance of 60 m, for 48 h. Temporary impairment due to TTS could occur at similar short distances if fish remain at the same point within the sound field for long periods of time (12 h). The distances are farther for the MODU, and smallest for the FPSO without DP (Table 49).

For offtake operations, recoverable injury and temporary impairment could happen if fish remain within planar distances of <20 m and 40 m, respectively, from the FPSO or the OSV thrusters. There is no increased risk to fish from aggregate scenarios, with ranges to thresholds from the individual sources unchanged.

6. Glossary

1/3-octave
One third of an octave. Note: A one-third octave is approximately equal to one decidecade (1/3 oct ≈ 1.003 ddec; ISO 2017).

1/3-octave-band
Frequency band whose bandwidth is one one-third octave. Note: The bandwidth of a one-third octave-band increases with increasing centre frequency.

absorption
The reduction of acoustic pressure amplitude due to acoustic particle motion energy converting to heat in the propagation medium.

acoustic impedance
The ratio of the sound pressure in a medium to the rate of alternating flow of the medium through a specified surface due to the sound wave.

ambient noise
All-encompassing sound at a given place, usually a composite of sound from many sources near and far (ANSI S1.1-1994 R2004), e.g., shipping vessels, seismic activity, precipitation, sea ice movement, wave action, and biological activity.

attenuation
The gradual loss of acoustic energy from absorption and scattering as sound propagates through a medium.

Auditory frequency weighting (auditory weighting function, frequency-weighting function)
The process of band-pass filtering sounds to reduce the importance of inaudible or less-audible frequencies for individual species or groups of species of aquatic mammals (ISO 2017). One example is M-weighting introduced by Southall et al. (2007) to describe "Generalized frequency weightings for various functional hearing groups of marine mammals, allowing for their functional bandwidths and appropriate in characterizing auditory effects of strong sounds".

azimuth
A horizontal angle relative to a reference direction, which is often magnetic north or the direction of travel. In navigation it is also called bearing.

bandwidth
The range of frequencies over which a sound occurs. Broadband refers to a source that produces sound over a broad range of frequencies (e.g., seismic airguns, vessels) whereas narrowband sources produce sounds over a narrow frequency range (e.g., sonar) (ANSI/ASA S1.13-2005 R2010).

bar
Unit of pressure equal to 100 kPa, which is approximately equal to the atmospheric pressure on Earth at sea level. 1 bar is equal to 10^5 Pa or 10^{11} µPa.

broadband sound level
The total sound pressure level measured over a specified frequency range. If the frequency range is unspecified, it refers to the entire measured frequency range.

broadside direction
Perpendicular to the travel direction of a source. Compare with endfire direction.

cavitation
A rapid formation and collapse of vapor cavities (i.e., bubbles or voids) in water, most often caused by a rapid change in pressure. Fast-spinning vessel propellers typically cause cavitation, which creates a lot of noise.

cetacean
Any animal in the order Cetacea. These are aquatic, mostly marine mammals and include whales, dolphins, and porpoises.

compressional wave
A mechanical vibration wave in which the direction of particle motion is parallel to the direction of propagation. Also called primary wave or P-wave.

continuous sound
A sound whose sound pressure level remains above ambient sound during the observation period (ANSI/ASA S1.13-2005 R2010). A sound that gradually varies in intensity with time, for example, sound from a marine vessel.

decade
Logarithmic frequency interval whose upper bound is ten times larger than its lower bound (ISO 2006).

decidecade
One tenth of a decade (ISO 2017). Note: An alternative name for decidecade (symbol ddec) is "one-tenth decade". A decidecade is approximately equal to one third of an octave (1 ddec ≈ 0.3322 oct) and for this reason is sometimes referred to as a "one-third octave".

decidecade band
Frequency band whose bandwidth is one decidecade. Note: The bandwidth of a decidecade band increases with increasing centre frequency.

decibel (dB)
One-tenth of a bel. Unit of level when the base of the logarithm is the tenth root of ten, and the quantities concerned are proportional to power (ANSI S1.1-1994 R2004).

endfire direction
Parallel to the travel direction of a source. See also broadside direction.

ensonified
Exposed to sound.

far-field
The zone where, to an observer, sound originating from an array of sources (or a spatially distributed source) appears to radiate from a single point. The distance to the acoustic far-field increases with frequency.

fast-average sound pressure level
The time-averaged sound pressure levels calculated over the duration of a pulse (e.g., 90%-energy time window), using the leaky time integrator from Plomp and Bouman (1959) and a time constant of 125 ms. Typically used only for pulsed sounds.

fast Fourier transform (FFT)
A computationally efficiently algorithm for computing the discrete Fourier transform.

frequency
The rate of oscillation of a periodic function measured in cycles-per-unit-time. The reciprocal of the period. Unit: hertz (Hz). Symbol: *f*. 1 Hz is equal to 1 cycle per second.

hearing group
Groups of marine mammal species with similar hearing ranges. Commonly defined functional hearing groups include low-, mid-, and high-frequency cetaceans, pinnipeds in water, and pinnipeds in air.

geoacoustic
Relating to the acoustic properties of the seabed.

hearing threshold
The sound pressure level for any frequency of the hearing group that is barely audible for a given individual in the absence of significant background noise during a specific percentage of experimental trials.

hertz (Hz)
A unit of frequency defined as one cycle per second.

high-frequency (HF) cetacean
The functional cetacean hearing group that represents those odontocetes (toothed whales) specialized for hearing high frequencies.

intermittent sound
A level of sound that abruptly drops to the background noise level several times during the observation period.

impulsive sound
Sound that is typically brief and intermittent with rapid (within a few seconds) rise time and decay back to ambient levels (NOAA 2013, ANSI S12.7-1986 R2006). For example, seismic airguns and impact pile driving.

low-frequency (LF) cetacean
The functional cetacean hearing group that represents mysticetes (baleen whales) specialized for hearing low frequencies.

masking
Obscuring of sounds of interest by sounds at similar frequencies.

median
The 50th percentile of a statistical distribution.

mid-frequency (MF) cetacean
The functional cetacean hearing group that represents those odontocetes (toothed whales) specialized for mid-frequency hearing.

Monte Carlo simulation
The method of investigating the distribution of a non-linear multi-variate function by random sampling of all of its input variable distributions.

mysticete
Mysticeti, a suborder of cetaceans, use their baleen plates, rather than teeth, to filter food from water. They are not known to echolocate, but they use sound for communication. Members of this group include rorquals (Balaenopteridae), right whales (Balaenidae), and grey whales (*Eschrichtius robustus*).

non-impulsive sound
Sound that is broadband, narrowband or tonal, brief or prolonged, continuous or intermittent, and typically does not have a high peak pressure with rapid rise time (typically only small fluctuations in decibel level) that impulsive signals have (ANSI/ASA S3.20-1995 R2008). For example, marine vessels, aircraft, machinery, construction, and vibratory pile driving (NIOSH 1998, NOAA 2015).

octave
The interval between a sound and another sound with double or half the frequency. For example, one octave above 200 Hz is 400 Hz, and one octave below 200 Hz is 100 Hz.

odontocete
The presence of teeth, rather than baleen, characterizes these whales. Members of the Odontoceti are a suborder of cetaceans, a group comprised of whales, dolphins, and porpoises. The skulls of toothed whales are mostly asymmetric, an adaptation for their echolocation. This group includes sperm whales, killer whales, belugas, narwhals, dolphins, and porpoises.

otariid
A common term used to describe members of the Otariidae, eared seals, commonly called sea lions and fur seals. Otariids are adapted to a semi-aquatic life; they use their large fore flippers for propulsion. Their ears distinguish them from phocids. Otariids are one of the three main groups in the superfamily Pinnipedia; the other two groups are phocids and walrus.

parabolic equation method
A computationally efficient solution to the acoustic wave equation that is used to model transmission loss. The parabolic equation approximation omits effects of back-scattered sound, simplifying the computation of transmission loss. The effect of back-scattered sound is negligible for most ocean-acoustic propagation problems.

particle velocity
The physical speed of a particle in a material moving back and forth in the direction of the pressure wave. Unit: metre per second (m/s). Symbol: v.

peak pressure level (PK)
The maximum instantaneous sound pressure level, in a stated frequency band, within a stated period. Also called zero-to-peak pressure level. Unit: decibel (dB).

peak-to-peak pressure level (PK-PK)
The difference between the maximum and minimum instantaneous pressure levels. Unit: decibel (dB).

percentile level, exceedance
The sound level exceeded n% of the time during a measurement.

permanent threshold shift (PTS)
A permanent loss of hearing sensitivity caused by excessive noise exposure. PTS is considered auditory injury.

phocid
A common term used to describe all members of the family Phocidae. These true/earless seals are more adapted to in-water life than are otariids, which have more terrestrial adaptations. Phocids use their hind flippers to propel themselves. Phocids are one of the three main groups in the superfamily Pinnipedia; the other two groups are otariids and walrus.

phocid pinnipeds in water (PPW)
The functional pinniped hearing group that represents true/earless seals under water.

pinniped
A common term used to describe all three groups that form the superfamily Pinnipedia: phocids (true seals or earless seals), otariids (eared seals or fur seals and sea lions), and walrus.

point source
A source that radiates sound as if from a single point (ANSI S1.1-1994 R2004).

pressure, acoustic
The deviation from the ambient hydrostatic pressure caused by a sound wave. Also called overpressure. Unit: pascal (Pa). Symbol: p.

pressure, hydrostatic
The pressure at any given depth in a static liquid that is the result of the weight of the liquid acting on a unit area at that depth, plus any pressure acting on the surface of the liquid. Unit: pascal (Pa).

received level (RL)
The sound level measured (or that would be measured) at a defined location.

rms
root-mean-square.

signature
Pressure signal generated by a source.

sound
A time-varying pressure disturbance generated by mechanical vibration waves travelling through a fluid medium such as air or water.

sound exposure
Time integral of squared, instantaneous frequency-weighted sound pressure over a stated time interval or event. Unit: pascal-squared second ($Pa^2 \cdot s$) (ANSI S1.1-1994 R2004).

sound exposure level (SEL)
A cumulative measure related to the sound energy in one or more pulses. Unit: dB re 1 $\mu Pa^2 \cdot s$. SEL is expressed over the summation period (e.g., per-pulse SEL [for airguns], single-strike SEL [for pile drivers], 24-hour SEL).

sound exposure spectral density
Distribution as a function of frequency of the time-integrated squared sound pressure per unit bandwidth of a sound having a continuous spectrum (ANSI S1.1-1994 R2004). Unit: $\mu Pa^2 \cdot s/Hz$.

sound field
Region containing sound waves (ANSI S1.1-1994 R2004).

sound intensity
Sound energy flowing through a unit area perpendicular to the direction of propagation per unit time.

sound pressure level (SPL)
The decibel ratio of the time-mean-square sound pressure, in a stated frequency band, to the square of the reference sound pressure (ANSI S1.1-1994 R2004).

For sound in water, the reference sound pressure is one micropascal (p_0 = 1 μPa) and the unit for SPL is dB re 1 μPa^2:

$$L_p = 10 \log_{10}(p^2/p_0^2) = 20 \log_{10}(p/p_0)$$

Unless otherwise stated, SPL refers to the root-mean-square (rms) pressure level. See also 90% sound pressure level and fast-average sound pressure level. Non-rectangular time window functions may be applied during calculation of the rms value, in which case the SPL unit should identify the window type.

sound speed profile
The speed of sound in the water column as a function of depth below the water surface.

source level (SL)
The sound level measured in the far-field and scaled back to a standard reference distance of 1 metre from the acoustic centre of the source. Unit: dB re 1 μPa·m (pressure level) or dB re 1 $\mu Pa^2 \cdot s \cdot m$ (exposure level).

spectrogram
A visual representation of acoustic amplitude compared with time and frequency.

spectrum
An acoustic signal represented in terms of its power, energy, mean-square sound pressure, or sound exposure distribution with frequency.

temporary threshold shift (TTS)
Temporary loss of hearing sensitivity caused by excessive noise exposure.

transmission loss (TL)
The decibel reduction in sound level between two stated points that results from sound spreading away from an acoustic source subject to the influence of the surrounding environment. Also referred to as propagation loss.

wavelength
Distance over which a wave completes one cycle of oscillation. Unit: metre (m). Symbol: λ.

Appendix A. Acoustic Metrics

A.1. Pressure Related Acoustic Metrics

Underwater sound pressure amplitude is measured in decibels (dB) relative to a fixed reference pressure of p_0 = 1 μPa. Because the perceived loudness of sound, especially impulsive noise such as from seismic airguns, pile driving, and sonar, is not generally proportional to the instantaneous acoustic pressure, several sound level metrics are commonly used to evaluate noise and its effects on marine life. We provide specific definitions of relevant metrics used in the accompanying report. Where possible we follow the ANSI and ISO standard definitions and symbols for sound metrics, but these standards are not always consistent.

The zero-to-peak sound pressure level (PK; L_{pk}; $L_{p,pk}$; dB re 1 μPa), is the maximum instantaneous sound pressure level in a stated frequency band attained by an acoustic pressure signal, *p*(*t*):

$$L_{p,pk} = 20\log_{10}\left[\frac{\max(|p(t)|)}{p_0}\right] \tag{A-1}$$

PK is often included as a criterion for assessing whether a sound is potentially injurious; however, because it does not account for the duration of a noise event, it is generally a poor indicator of perceived loudness.

The peak-to-peak sound pressure level (PK-PK; $L_{pk\text{-}pk}$; $L_{p,pk\text{-}pk}$; dB re 1 μPa) is the difference between the maximum and minimum instantaneous sound pressure levels in a stated frequency band attained by an impulsive sound, *p*(*t*):

$$L_{p,pk-pk} = 10\log_{10}\left\{\frac{[\max(p(t)) - \min(p(t))]^2}{p_0^2}\right\} \tag{A-2}$$

The sound pressure level (SPL; L_p; dB re 1 μPa) is the rms pressure level in a stated frequency band over a specified time window (*T*, s) containing the acoustic event of interest. It is important to note that SPL always refers to a rms pressure level and therefore not instantaneous pressure:

$$L_p = 10\log_{10}\left(\frac{1}{T}\int_T p^2(t)dt \Big/ p_0^2\right) \tag{A-3}$$

The SPL represents a nominal effective continuous sound over the duration of an acoustic event, such as the emission of one acoustic pulse, a marine mammal vocalization, the passage of a vessel, or over a fixed duration. Because the window length, *T*, is the divisor, events with similar sound exposure level (SEL) but more spread out in time have a lower SPL. A fixed window length of 0.125 s (critical duration defined by Tougaard et al. (2015)) is used in this study for impulsive sounds.

The sound exposure level (SEL; L_E; $L_{E,p}$; dB re 1 μPa²·s) is a measure related to the acoustic energy contained in one or more acoustic events (*N*). The SEL for a single event is computed from the time-integral of the squared pressure over the full event duration (*T*):

$$L_E = 10\log_{10}\left(\int_T p^2(t)dt \Big/ T_0 p_0^2\right) \tag{A-4}$$

where T_0 is a reference time interval of 1 s. The SEL continues to increase with time when non-zero pressure signals are present. It therefore can be construed as a dose-type measurement, so the integration time used must be carefully considered in terms of relevance for impact to the exposed recipients.

SEL can be calculated over periods with multiple acoustic events or over a fixed duration. For a fixed duration, the square pressure is integrated over the duration of interest. For multiple events, SEL can be computed by summing (in linear units) SEL of the *N* individual events:

$$L_{E,N} = 10\log_{10}\left(\sum_{i=1}^{N} 10^{\frac{L_{E,i}}{10}}\right) . \qquad \text{(A-5)}$$

If applied, the frequency weighting of an acoustic event should be specified, as in the case of weighted SEL (e.g., $L_{E,LFC,24h}$; Appendix A.3). The use of fast, slow, or impulse exponential-time-averaging or other time-related characteristics should else be specified.

A.2. Marine Mammal Impact Criteria

It has been long recognised that marine mammals can be adversely affected by underwater anthropogenic noise. For example, Payne and Webb (1971) suggested that communication distances of fin whales are reduced by shipping sounds. Subsequently, similar concerns arose regarding effects of other underwater noise sources and the possibility that impulsive sources—primarily airguns used in seismic surveys—could cause auditory injury. This led to a series of workshops held in the late 1990s, conducted to address acoustic mitigation requirements for seismic surveys and other underwater noise sources (NMFS 1998, ONR 1998, Nedwell and Turnpenny 1998, HESS 1999, Ellison and Stein 1999). In the years since these early workshops, a variety of thresholds have been proposed for both injury and disturbance. The following sections summarize the recent development of thresholds; however, this field remains an active research topic.

A.2.1. Injury

In recognition of shortcomings of the SPL-only based injury criteria, in 2005 NMFS sponsored the Noise Criteria Group to review literature on marine mammal hearing to propose new noise exposure criteria. Some members of this expert group published a landmark paper (Southall et al. 2007) that suggested assessment methods similar to those applied for humans. The resulting recommendations introduced dual acoustic injury criteria for impulsive sounds that included peak pressure level thresholds and SEL_{24h} thresholds, where the subscripted 24h refers to the accumulation period for calculating SEL. The peak pressure level criterion is not frequency weighted whereas SEL_{24h} is frequency weighted according to one of four marine mammal species hearing groups: low-, mid- and high-frequency cetaceans (LF, MF, and HF cetaceans, respectively) and Pinnipeds in Water (PINN). These weighting functions are referred to as M-weighting filters (analogous to the A-weighting filter for human; Appendix A.3). The SEL_{24h} thresholds were obtained by extrapolating measurements of onset levels of Temporary Threshold Shift (TTS) in belugas by the amount of TTS required to produce Permanent Threshold Shift (PTS) in chinchillas. The Southall et al. (2007) recommendations do not specify an exchange rate, which suggests that the thresholds are the same regardless of the duration of exposure (i.e., it implies a 3 dB exchange rate).

Wood et al. (2012) refined Southall et al.'s (2007) thresholds, suggesting lower injury values for LF and HF cetaceans while retaining the filter shapes. Their revised thresholds were based on TTS-onset levels in harbour porpoises from Lucke et al. (2009), which led to a revised impulsive sound PTS threshold for HF cetaceans of 179 dB re 1 $\mu\text{Pa}^2\cdot\text{s}$. Because there were no data available for baleen whales, Wood et al. (2012) based their recommendations for LF cetaceans on results obtained from MF cetacean studies. In particular they referenced Finneran and Schlundt (2010) research, which found mid-frequency cetaceans are more sensitive to non-impulsive sound exposure than Southall et al. (2007) assumed. Wood et al. (2012) thus recommended a more conservative TTS-onset level for LF cetaceans of 192 dB re 1 $\mu\text{Pa}^2\cdot\text{s}$.

As of 2017, an optimal approach is not apparent. There is consensus in the research community that an SEL-based method is preferable either separately or in addition to an SPL-based approach to assess the potential for injuries. In August 2016, after substantial public and expert input into three draft versions and based largely on the above-mentioned literature (NOAA 2013, 2015, 2016), NMFS finalised technical guidance for assessing the effect of anthropogenic sound on marine mammal hearing (NMFS 2016). The guidance describes injury criteria with new thresholds and frequency weighting functions for the five hearing groups described by Finneran and Jenkins (2012). The latest revision to this work was published in 2018 (NMFS 2018). Southall et al. (2019) revisited the interim criteria published in 2007; all noise exposure criteria in NMFS (2018) and Southall et al. (2019) are identical (for impulsive and non-impulsive sounds), however the mid-frequency cetaceans from NMFS (2018) are classified as high-frequency cetaceans in Southall et al. (2019), and high-frequency cetaceans from NMFS (2018) are classified as very-high-frequency cetaceans in Southall et al. (2019). This report continues to apply the terminology from NMFS (2018) for consistency with other projects.

A.3. Marine Mammal Frequency Weighting

The potential for noise to affect animals depends on how well the animals can hear it. Noises are less likely to disturb or injure an animal if they are at frequencies that the animal cannot hear well. An exception occurs when the sound pressure is so high that it can physically injure an animal by non-auditory means (i.e., barotrauma). For sound levels below such extremes, the importance of sound components at particular frequencies can be scaled by frequency weighting relevant to an animal’s sensitivity to those frequencies (Nedwell and Turnpenny 1998, Nedwell et al. 2007).

A.3.1. Marine mammal frequency weighting functions

In 2015, a U.S. Navy technical report by Finneran (2015) recommended new auditory weighting functions. The overall shape of the auditory weighting functions is similar to human A-weighting functions, which follows the sensitivity of the human ear at low sound levels. The new frequency-weighting function is expressed as:

$$G(f) = K + 10\log_{10}\left[\left(\frac{(f/f_{lo})^{2a}}{\left[1+(f/f_{lo})^2\right]^a\left[1+(f/f_{hi})^2\right]^b}\right)\right] \tag{A-6}$$

Finneran (2015) proposed five functional hearing groups for marine mammals in water: low-, mid-, and high-frequency cetaceans, phocid pinnipeds, and otariid pinnipeds. The parameters for these frequency-weighting functions were further modified the following year (Finneran 2016) and were adopted in NOAA’s technical guidance that assesses noise impacts on marine mammals (NMFS 2016, NMFS 2018). Table A-1 lists the frequency-weighting parameters for each hearing group; Figure A-1 shows the resulting frequency-weighting curves.

Table A-1. Parameters for the auditory weighting functions used in this project as recommended by NMFS (2018).

Hearing group	**a**	**b**	**f_{lo} (Hz)**	**f_{hi} (kHz)**	***K* (dB)**
LF cetaceans (baleen whales)	1.0	2	200	19,000	0.13
MF cetaceans (dolphins, plus toothed, beaked, and bottlenose whales)	1.6	2	8,800	110,000	1.20
HF cetaceans (true porpoises, *Kogia*, river dolphins, cephalorhynchid, *Lagenorhynchus cruciger* and *L. australis*)	1.8	2	12,000	140,000	1.36

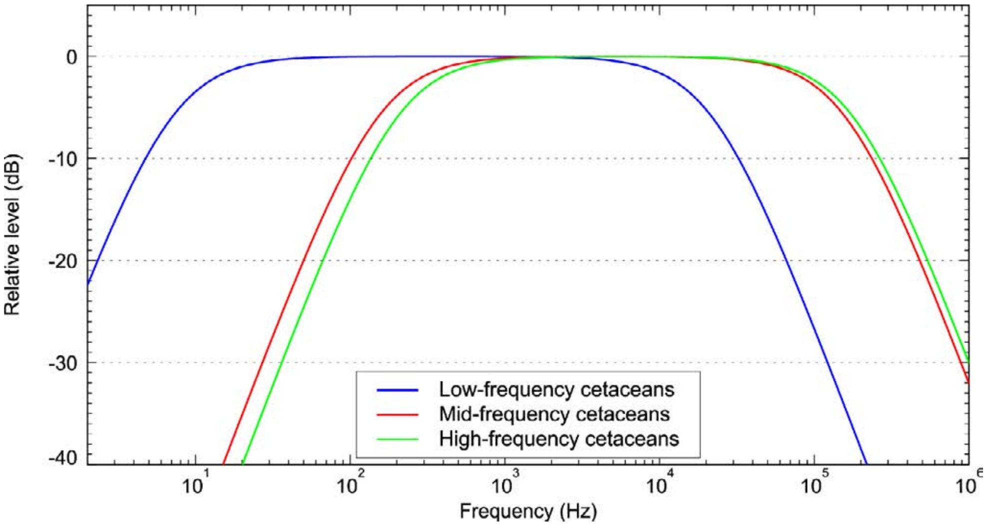

Figure A-1. Auditory weighting functions for functional marine mammal hearing groups as recommended by NMFS (2018).

Appendix B. Pile Driving Acoustic Source Model

A physical model of pile vibration and near-field sound radiation is used to calculate source levels of piles. The physical model employed in this study computes the underwater vibration and sound radiation of a pile by solving the theoretical equations of motion for axial and radial vibrations of a cylindrical shell. These equations of motion are solved subject to boundary conditions, which describe the forcing function of the hammer at the top of the pile and the soil resistance at the base of the pile (Figure B-1). Damping of the pile vibration due to radiation loading is computed for Mach waves emanating from the pile wall. The equations of motion are discretised using the finite difference (FD) method and are solved on a discrete time and depth mesh.

To model the sound emissions from the piles, the force of the pile driving hammers also had to be modelled. The force at the top of each pile was computed using the GRLWEAP 2010 wave equation model (GRLWEAP, Pile Dynamics 2010), which includes a large database of simulated hammers—both impact and vibratory—based on the manufacturer’s specifications. The forcing functions from GRLWEAP were used as inputs to the FD model to compute the resulting pile vibrations.

The sound radiating from the pile itself is simulated using a vertical VSP array of discrete point sources. The point sources are centred on the pile axis. Their amplitudes are derived using an inverse technique, such that their collective particle velocity—calculated using a near-field wave-number integration model—matches the particle velocity in the water at the pile wall. The sound field propagating away from the vertical source VSP array is then calculated using a time-domain acoustic propagation model (FWRAM, Appendix E.2). MacGillivray (2014) describes the theory behind the physical model in more detail. The accuracy of JASCO's pile driving model has been verified by comparing its output against benchmark scenarios (Lippert et al. 2016) and detailed measurement programs (Austin et al. 2016, Denes et al. 2016, MacGillivray 2018).

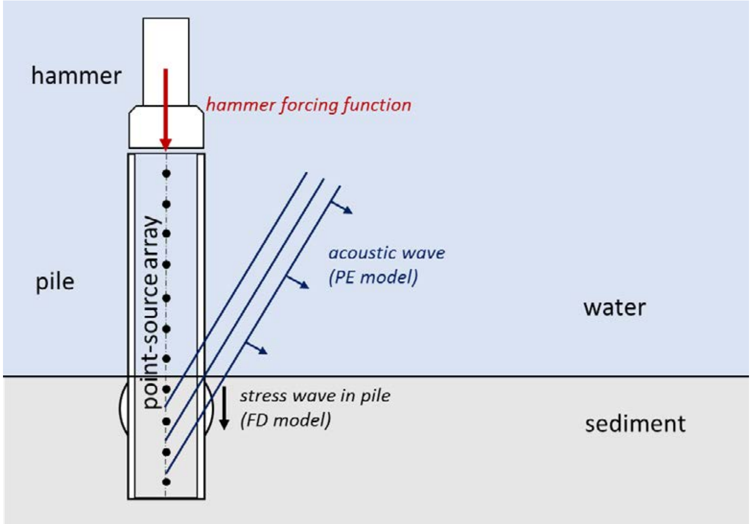

Figure B-1. Physical model geometry for impact driving of a cylindrical pile (vertical cross-section). The hammer forcing function is used with the finite difference (FD) model to compute the stress wave vibration in the pile. A vertical VSP array of point sources is used with the parabolic equation (PE) model to compute the acoustic waves that the pile wall radiates.

Appendix C. VSP Source

C.1. Airgun Array Source Model

The source levels and directivity of the seismic source were predicted with JASCO's Airgun Array Source Model (AASM). AASM includes low- and high-frequency modules for predicting different components of the seismic source spectrum. The low-frequency module is based on the physics of oscillation and radiation of airgun bubbles, as originally described by Ziolkowski (1970), that solves the set of parallel differential equations that govern bubble oscillations. Physical effects accounted for in the simulation include pressure interactions between airguns, port throttling, bubble damping, and generator-injector (GI) gun behaviour discussed by Dragoset (1984), Laws et al. (1990), and Landro (1992). A global optimisation algorithm tunes free parameters in the model to a large library of airgun source signatures.

While airgun signatures are highly repeatable at the low frequencies, which are used for seismic imaging, their sound emissions have a large random component at higher frequencies that cannot be predicted using a deterministic model. Therefore, AASM uses a stochastic simulation to predict the high-frequency (800−25,000 Hz) sound emissions of individual airguns, using a data-driven multiple-regression model. The multiple-regression model is based on a statistical analysis of a large collection of high quality seismic source signature data recently obtained from the Joint Industry Program (JIP) on Sound and Marine Life (Mattsson and Jenkerson 2008). The stochastic model uses a Monte-Carlo simulation to simulate the random component of the high-frequency spectrum of each airgun in an array. The mean high-frequency spectra from the stochastic model augment the low-frequency signatures from the physical model, allowing AASM to predict airgun source levels at frequencies up to 25,000 Hz.

AASM produces a set of "notional" signatures for each array element based on:

- Array layout
- Volume, operating depth, and firing pressure of each airgun
- Interactions between different airguns in the array

These notional signatures are the pressure waveforms of the individual airguns at a standard reference distance of 1 m; they account for the interactions with the other airguns in the array. The signatures are summed with the appropriate phase delays to obtain the far-field source signature of the entire array in all directions. This far-field array signature is filtered into 1/3-octave-bands to compute the source levels of the array as a function of frequency band and azimuthal angle in the horizontal plane (at the source depth), after which it is considered a directional point source in the far field.

A seismic array consists of many sources and the point source assumption is invalid in the near field where the array elements add incoherently. The maximum extent of the near field of an array (R_{nf}) is:

$$R_{\mathrm{nf}} < \frac{l^2}{4\lambda} \quad \text{(C-1)}$$

where λ is the sound wavelength and l is the longest dimension of the array (Lurton 2002, §5.2.4). For example, a seismic source length of l = 21 m yields a near-field range of 147 m at 2 kHz and 7 m at 100 Hz. Beyond this R_{nf} range, the array is assumed to radiate like a directional point source and is treated as such for propagation modelling.

The interactions between individual elements of the array create directionality in the overall acoustic emission. Generally, this directionality is prominent mainly at frequencies in the mid-range between tens of hertz to several hundred hertz. At lower frequencies, with acoustic wavelengths much larger than the inter-airgun separation distances, the directionality is small. At higher frequencies, the pattern of lobes is too finely spaced to be resolved and the effective directivity is less.

C.2. VSP Source Parameters

The layout of the seismic source is provided in Figure F-1. Details of the airgun parameters are provided in Table C-1.

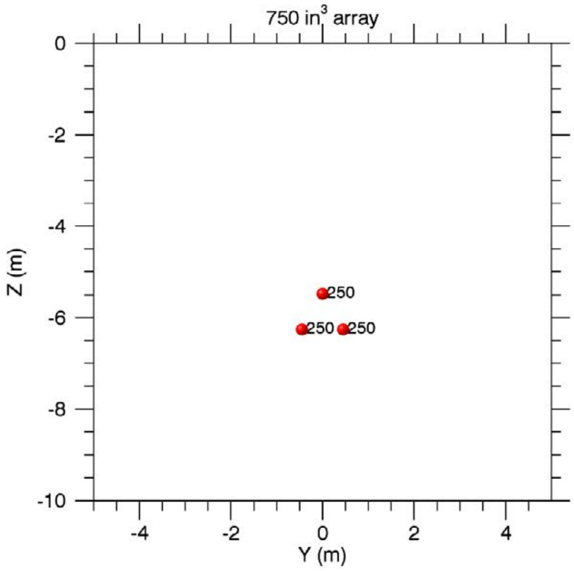

Figure C-1. Layout of the modelled 750 in^3 seismic source array. Operational depth is 6 m. The labels indicate the firing volume (in cubic inches) for each airgun. Also see Table C-1.

Table C-1. Layout of the modelled 750 in^3 seismic source array. Operational depth is 6 m. Firing pressure for all guns is 1800 psi. Also see Figure C-1.

Gun	x (m)	y (m)	z (m)	Volume (in^3)
1	0	0	5.48	250
2	0	-0.45	6.26	250
3	0	0.45	6.26	250

C.3. Array Source Levels and Directivity

Figure C-2 shows the broadside (perpendicular to the tow direction), endfire (parallel to the operational direction), and vertical overpressure signature and corresponding power spectrum levels for the 750 in^3 array (Appendix C.2). Horizontal 1/3-octave-band source levels shown as a function of band centre frequency and azimuth (Figure C-3) indicate that this array is mainly isotropic.

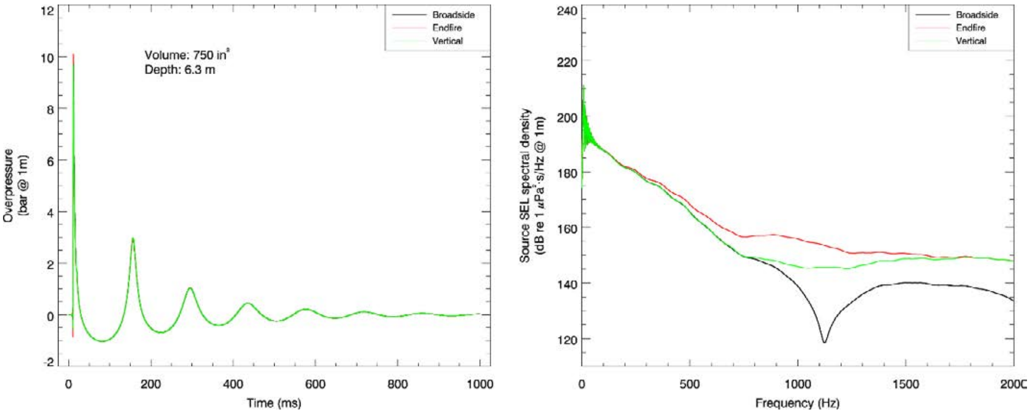

Figure C-2. Predicted source level details for the 750 in^3 array at a 6 m operational depth.(Left) the overpressure signature and (right) the power spectrum for in-plane horizontal (broadside), perpendicular (endfire), and vertical directions.

f = 1995 Hz

Figure C-3. Directionality of the predicted horizontal source levels for the 750 in^3 seismic source array, 10 Hz to 2 kHz. Source levels (in dB re 1 µPa^2·s m^2) are shown as a function of azimuth for the centre frequencies of the 1/3-octave-bands modelled; frequencies are shown above the plots. The perpendicular direction to the frame is to the right. Operational depth is 6 m.

Appendix D. Thruster Source Level Estimation

Underwater sound that radiates from vessels is produced mainly by propeller and thruster cavitation, with a smaller fraction of sound produced by sound transmitted through the hull, such as by engines, gearing, and other mechanical systems. Sound levels tend to be the highest when thrusters are used to position the vessel and when the vessel is transiting at high speeds. A vessel's sound signature depends on the vessel's size, power output, propulsion system, and the design characteristics of the given system (e.g., blade shape and size). A vessel produces broadband acoustic energy with most of the energy emitted below a few kilohertz. Sound from onboard machinery, particularly sound below 200 Hz, dominates the sound spectrum before cavitation begins—normally around 8–12 knots on many commercial vessels (Spence et al. 2007). Under higher speeds and higher propulsion system load, the acoustic output from the cavitation processes on the propeller blades dominates other sources of sound on the vessel such as machinery or hull vibration (Leggat et al. 1981).

A vessel equipped with propellers/thrusters has two primary sources of sound that propagate from the unit: the machinery and the propellers. For thrusters operating in the heavily loaded conditions, the acoustic energy generated by the cavitation processes on the propeller blades dominates (Leggat et al. 1981). The sound power from the propellers is proportional to the number of blades, the propeller diameter, and the propeller tip speed.

Based on an analysis of acoustic data, Ross (1976) provided the following formula for the sound levels from a vessel's propeller, operating in calm, open ocean conditions:

$$L_{100} = 155 + 60\log(u/25) + 10\log(B/4)\ , \qquad \text{(D-1)}$$

where L_{100} is the spectrum level at 100 Hz, u is the propeller tip speed (m/s), and B is the number of propeller blades. Equation D-1 gives the total energy produced by the propeller cavitation at frequencies between 100 Hz and 10 kHz. This equation is valid for a propeller tip speed between 15 and 50 m/s. The spectrum is assumed to be flat below 100 Hz. Its level is assumed to fall off at a rate of −6 dB per octave above 100 Hz (Figure D-1).

Another method of predicting the source level of a propeller was suggested by Brown (1977). For propellers operating in heavily loaded conditions, the formula for the sound spectrum level is:

$$\mathrm{SL}_B = 163 + 40\log D + 30\log N + 10\log B + 20\log f + 10\log(A_c/A_D)\ , \qquad \text{(D-2)}$$

where D is the propeller diameter (m), N is the propeller revolution rate per second, B is the number of blades, A_C is the area of the blades covered by cavitation, and A_D is the total propeller disc area. Similar to Ross's approach, the spectrum below 100 Hz is assumed to be flat. The tests with a naval propeller operating at off-design heavily loaded conditions showed that Equation D-2 should be used with a value of $(A_c/A_D) = 1$ (Leggat et al. 1981).

The combined source level for multiple thrusters operating together can be estimated using the formula:

$$\mathrm{SL}_{\mathrm{total}} = 10\log_{10}\sum_i 10^{\frac{SL_i}{10}}, \qquad \text{(D-3)}$$

where $\mathrm{SL}_{1,\ldots,N}$ are the source levels of individual thrusters. If the vessel is equipped with the same type of thrusters, the combined source level can be estimated using the formula:

$$\mathrm{SL}_N = \mathrm{SL} + 10\log N \qquad \text{(D-4)}$$

where N is the total number of thrusters of the same type.

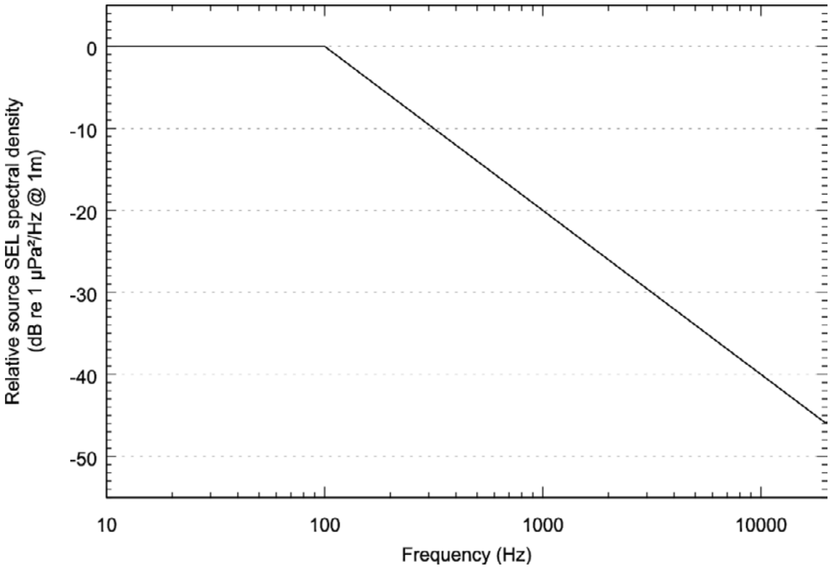

Figure D-1. Estimated sound spectrum from cavitating propeller (Leggat et al. 1981).

Appendix E. Sound Propagation Models

E.1. Transmission Loss

The propagation of sound through the environment was modelled by predicting the acoustic transmission loss—a measure, in decibels, of the decrease in sound level between a source and a receiver some distance away. Geometric spreading of acoustic waves is the predominant way by which transmission loss occurs. Transmission loss also happens when the sound is absorbed and scattered by the seawater, and absorbed scattered, and reflected at the water surface and within the seabed. Transmission loss depends on the acoustic properties of the ocean and seabed; its value changes with frequency.

If the acoustic source level (SL), expressed in dB re 1 µPa^{2}m^2, and transmission loss (TL), in units of dB, at a given frequency are known, then the received level (RL) at a receiver location can be calculated in dB re 1 µPa by:

$$\mathrm{RL} = \mathrm{SL} - \mathrm{TL} \tag{E-1}$$

E.2. Noise Propagation with FWRAM

For impulsive sounds from impact pile driving, time-domain representations of the pressure waves generated in the water are required to calculate SPL and peak pressure level. Furthermore, the pile must be represented as a distributed source to accurately characterise vertical directivity effects in the near-field zone. For this study, synthetic pressure waveforms were computed using JASCO's Full Waveform Range-dependent Acoustic Model (FWRAM). FWRAM computes acoustic propagation via a wide-angle parabolic equation solution to the acoustic wave equation (Collins 1993) based on a version of the U.S. Naval Research Laboratory's Range-dependent Acoustic Model (RAM), which has been modified to account for an elastic seabed (Zhang and Tindle 1995). The parabolic equation method has been extensively benchmarked and is widely employed in the underwater acoustics community (Collins et al. 1996). FWRAM accounts for the additional reflection loss at the seabed due to partial conversion of incident compressional waves to shear waves at the seabed and sub-bottom interfaces, and it includes wave attenuations in all layers. FWRAM incorporates the following site-specific environmental properties: a modelled area bathymetric grid, underwater sound speed as a function of depth, and a geoacoustic profile based on the overall stratified composition of the seafloor.

FWRAM computes pressure waveforms via Fourier synthesis of the modelled acoustic transfer function in closely spaced frequency bands. FWRAM employs the VSP array starter method to accurately model sound propagation from a spatially distributed source (MacGillivray and Chapman 2012).

Synthetic pressure waveforms from pile driving strikes were modelled and post-processed, after applying a travel time correction, to calculate standard SPL, SEL and PK metrics versus range and depth from the source.

E.3. MONM-BELLHOP

Long-range sound fields were computed using JASCO's Marine Operations Noise Model (MONM). Compared to VSTACK, MONM less accurately predicts steep-angle propagation for environments with higher shear speed but is well suited for effective longer-range estimation. This model computes sound propagation at frequencies of 10 Hz to 1.6 kHz via a wide-angle parabolic equation solution to the acoustic wave equation (Collins 1993) based on a version of the U.S. Naval Research Laboratory's Range-dependent Acoustic Model (RAM), which has been modified to account for a solid seabed (Zhang and Tindle 1995). MONM computes sound propagation at frequencies > 1.6 kHz via the BELLHOP Gaussian beam acoustic ray-trace model (Porter and Liu 1994).

The parabolic equation method has been extensively benchmarked and is widely employed in the underwater acoustics community (Collins et al. 1996). MONM accounts for the additional reflection loss at the seabed, which results from partial conversion of incident compressional waves to shear waves at the seabed and sub-bottom interfaces, and it includes wave attenuations in all layers. MONM incorporates the following site-specific environmental properties: a bathymetric grid of the modelled area, underwater sound speed as a function of depth, and a geoacoustic profile based on the overall stratified composition of the seafloor.

This version of MONM accounts for sound attenuation due to energy absorption through ion relaxation and viscosity of water in addition to acoustic attenuation due to reflection at the medium boundaries and internal layers (Fisher and Simmons 1977). The former type of sound attenuation is significant for frequencies higher than 5 kHz and cannot be neglected without noticeably affecting the model results.

MONM computes acoustic fields in three dimensions by modelling transmission loss within two-dimensional (2-D) vertical planes aligned along radials covering a 360° swath from the source, an approach commonly referred to as N×2-D. These vertical radial planes are separated by an angular step size of $\Delta\theta$, yielding N = 360°/$\Delta\theta$ number of planes (Figure E-1).

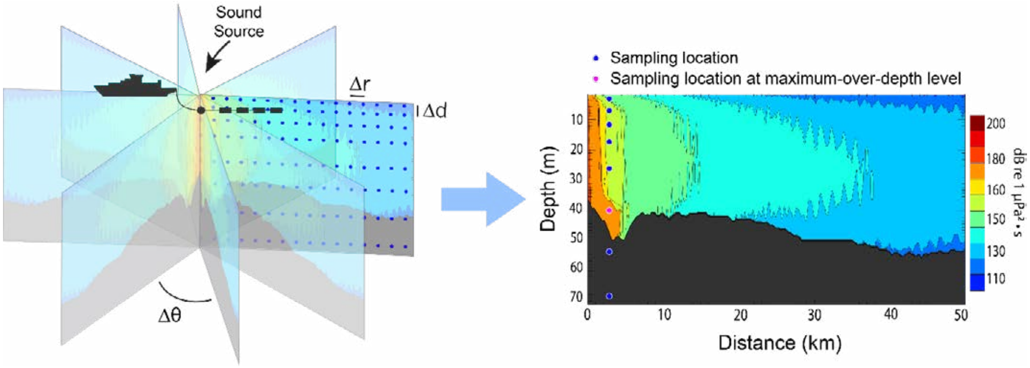

Figure E-1. The N×2-D and maximum-over-depth modelling approach used by MONM.

MONM treats frequency dependence by computing acoustic transmission loss at the centre frequencies of 1/3-octave-bands. Sufficiently many 1/3-octave-bands, starting at 10 Hz, are modelled to include most of the acoustic energy emitted by the source. At each centre frequency, the transmission loss is modelled within each of the N vertical planes as a function of depth and range from the source. The 1/3-octave-band received per-pulse SEL are computed by subtracting the band transmission loss values from the directional source level in that frequency band. Composite broadband received per-pulse SEL are then computed by summing the received 1/3-octave-band levels.

The received per-pulse (VSP source) or per-second vessel (MODU, FPSO, and OSV sources) SEL sound field within each vertical radial plane is sampled at various ranges from the source, generally with a fixed radial step size. At each sampling range along the surface, the sound field is sampled at various depths, with the step size between samples increasing with depth below the surface. The step sizes are chosen to provide increased coverage near the depth of the source and at depths of interest in terms of the sound speed profile. For areas with deep water, sampling is not performed at depths beyond those reachable by marine mammals. The received per-pulse or per-second SEL at a surface sampling location is taken as the maximum value that occurs over all samples within the water column, i.e., the maximum-over-depth received per-pulse SEL. These maximum-over-depth per-pulse SEL are presented as colour contours around the source.

An inherent variability in measured sound levels is caused by temporal variability in the environment and the variability in the signature of repeated acoustic impulses (sample sound source verification results is presented in Figure E-2). While MONM's predictions correspond to the averaged received levels, cautionary estimates of the threshold radii are obtained by shifting the best fit line (solid line, Figure E-2) upward so that the trend line encompasses 90% of all the data (dashed line, Figure E-2).

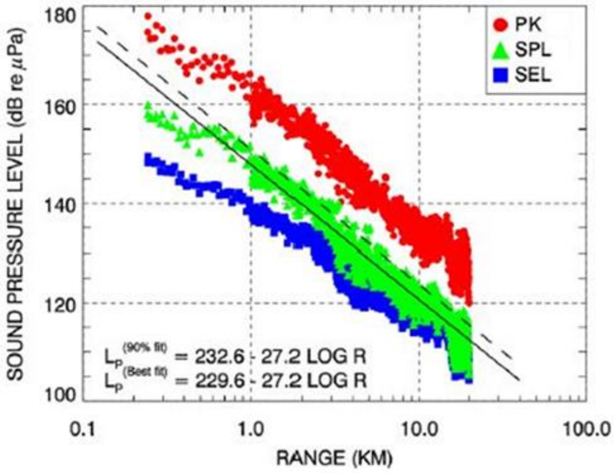

Figure E-2. PK and SPL and per-pulse SEL versus range from a 20 in^3 seismic source. Solid line is the least squares best fit to SPL. Dashed line is the best fit line increased by 3.0 dB to exceed 90% of all SPL values (90th percentile fit) (Ireland et al. 2009, Figure 10).

E.4. Wavenumber Integration Model

Sound pressure levels near the seismic source were modelled using JASCO's VSTACK wavenumber integration model. VSTACK computes synthetic pressure waveforms versus depth and range for arbitrarily layered, range-independent acoustic environments using the wavenumber integration approach to solve the exact (range-independent) acoustic wave equation. This model is valid over the full angular range of the wave equation and can fully account for the elasto-acoustic properties of the sub-bottom. Wavenumber integration methods are extensively used in the field of underwater acoustics and seismology where they are often referred to as reflectivity methods or discrete wavenumber methods. VSTACK computes sound propagation in arbitrarily stratified water and seabed layers by decomposing the outgoing field into a continuum of outward-propagating plane cylindrical waves. Seabed reflectivity in the model is dependent on the seabed layer properties: compressional and shear wave speeds, attenuation coefficients, and layer densities. The output of the model can be post-processed to yield estimates of the SEL, SPL, and PK.

VSTACK accurately predicts steep-angle propagation in the proximity of the source, but it is computationally slow at predicting sound pressures at large distances due to the need for smaller wavenumber steps with increasing distance. Additionally, VSTACK assumes range-invariant bathymetry with a horizontally stratified medium (i.e., a range-independent environment) which is azimuthally symmetric about the source. VSTACK is thus best suited to modelling the sound field near the source.

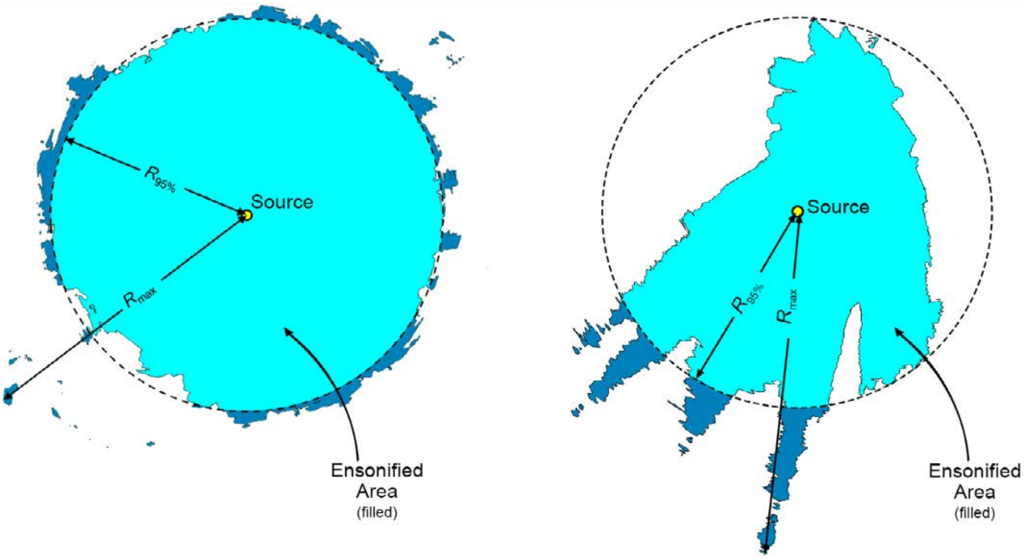
Appendix F. Methods and Parameters

This section describes the specifications of the seismic source that was used at all sites and the environmental parameters used in the propagation models.

F.1. Estimating Range to Thresholds Levels

Sound level contours were calculated based on the underwater sound fields predicted by the propagation models, sampled by taking the maximum value over all modelled depths above the sea floor for each location in the modelled region. The predicted distances to specific levels were computed from these contours. Two distances relative to the source are reported for each sound level: 1) R_{max}, the maximum range to the given sound level over all azimuths, and 2) $R_{95\%}$, the range to the given sound level after the 5% farthest points were excluded (see examples in Figure F-1).

The $R_{95\%}$ is used because sound field footprints are often irregular in shape. In some cases, a sound level contour might have small protrusions or anomalous isolated fringes. This is demonstrated in the image in Figure F-1(a). In cases such as this, where relatively few points are excluded in any given direction, R_{max} can misrepresent the area of the region exposed to such effects, and $R_{95\%}$ is considered more representative. In strongly asymmetric cases such as shown in Figure F-1(b), on the other hand, $R_{95\%}$ neglects to account for significant protrusions in the footprint. In such cases R_{max} might better represent the region of effect in specific directions. Cases such as this are usually associated with bathymetric features affecting propagation. The difference between R_{max} and $R_{95\%}$ depends on the source directivity and the non-uniformity of the acoustic environment.



(a) (b)

Figure F-1. Sample areas ensonified to an arbitrary sound level with R_{max} and $R_{95\%}$ ranges shown for two different scenarios. (a) Largely symmetric sound level contour with small protrusions. (b) Strongly asymmetric sound level contour with long protrusions. Light blue indicates the ensonified areas bounded by $R_{95\%}$; darker blue indicates the areas outside this boundary which determine R_{max}.

F.2. Estimating SPL from Modelled SEL Results

The per-pulse SEL of sound pulses is an energy-like metric related to the dose of sound received over a pulse's entire duration. The pulse SPL on the other hand, is related to its intensity over a specified time interval. Seismic pulses typically lengthen in duration as they propagate away from their source, due to seafloor and surface reflections, and other waveguide dispersion effects. The changes in pulse length, and therefore the time window considered, affect the numeric relationship between SPL and SEL. This study has applied a fixed window duration to calculate SPL (T_{fix} = 125 ms; see Appendix A.1), as implemented in Martin et al. (2017b). Full-waveform modelling was used to estimate SPL, but this type of modelling is computationally intensive, and can be prohibitively time consuming when run at high spatial resolution over large areas.

For the current study, FWRAM (Appendix E.2) was used to model synthetic seismic pulses over the frequency range 5–1024 Hz. This was performed along all broadside and endfire radials at two sites. FWRAM uses Fourier synthesis to recreate the signal in the time domain so that both the SEL and SPL from the source can be calculated. The differences between the SEL and SPL were extracted for all ranges and depths that corresponded to those generated from the high spatial-resolution results from MONM. A 125 ms fixed time window positioned to maximise the SPL over the pulse duration was applied. The resulting SEL -to-SPL offsets were averaged in 0.3 km range bins along each modelled radial and depth, and the 90th percentile was selected at each range to generate a generalised range-dependent conversion function for each site. The range- dependent conversion function was averaged between the two sites and applied to predicted per-pulse SEL results from MONM to model SPL values. Figure F-2 shows the conversion offsets for each site; the spatial variation is caused by changes in the received airgun pulse as it propagates from the source.

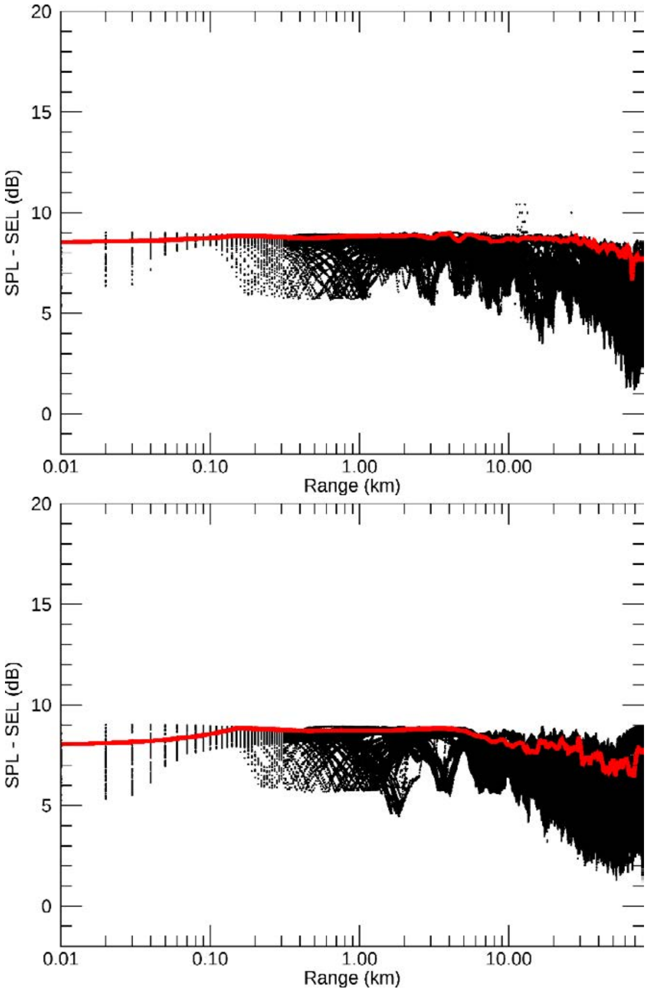


Figure F-2. Range-and-depth-dependent conversion offsets for converting SEL to SPL for seismic pulses for Torosa (top) and Brecknock (bottom) sites. Black dots are the modelled differences between SEL and SPL across different radials and receiver depths; the solid red line is the 90th percentile of the modelled differences at each range.

F.3. Environmental Parameters

F.3.1. Bathymetry

Water depths (Mean Sea Level) at close- and mid-range from the pile were provided by Woodside: within ~5–7 km from the pile, the data has a grid resolution of 2 m× 2 m, while data at the passage between Scott Reef South and Scott Reef Central has a grid resolution of 1 m× 1 m. Bathymetry data with grid resolution of 10 × 10 m was provided as far as 33 km northeast of the pile, and as far as 85 km southwest of the pile. Modelling was conducted along 80 km long radials emanating from the pile in all directions. For this reason, the high-resolution data was complemented using the Australian Bathymetry and Topography Grid, a 9 arc-second grid rendered for Australian waters (Whiteway 2009). The data were adjusted for an increase of 1.7 m in depth (Bureau of Meterology 2019), so the modelling results correspond to the most conservative propagation conditions at maximum tide at Scott Reef. Bathymetry data were re-gridded onto a Map Grid of Australia (MGA) coordinate projection (Zone 51) with a regular grid spacing of 50 × 50 m.

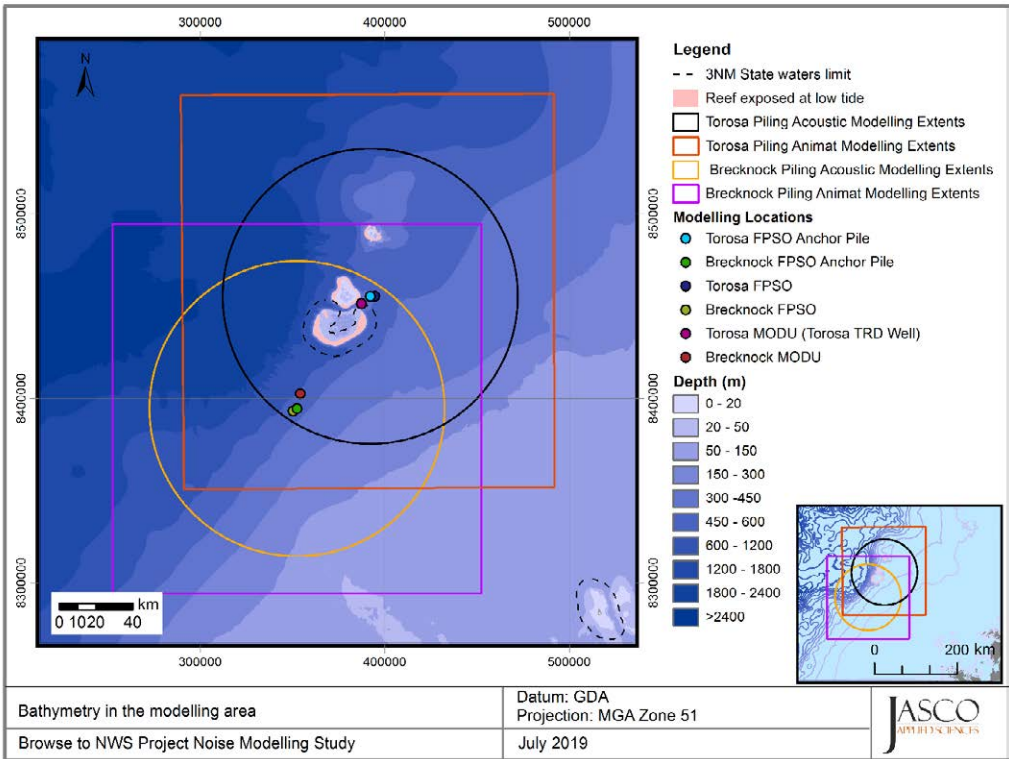

Figure F-3. Bathymetry in the modelled area.

F.3.2. Sound speed profile

The sound speed profile in the area was derived from temperature and salinity profiles from the U.S. Naval Oceanographic Office's *Generalized Digital Environmental Model V 3.0* (GDEM; Teague et al. 1990, Carnes 2009). GDEM provides an ocean climatology of temperature and salinity for the world's oceans on a latitude-longitude grid with 0.25° resolution, with a temporal resolution of one month, based on global historical observations from the U.S. Navy's Master Oceanographic Observational Data Set (MOODS). The climatology profiles include 78 fixed depth points to a maximum depth of 6800 m (where the ocean is that deep). The GDEM temperature-salinity profiles were converted to sound speed profiles according to Coppens (1981).

Mean monthly sound speed profiles were derived from the GDEM profiles at distances less than 76 km around the modelled site. The June sound speed profile is expected to be most favourable to longer-range sound propagation across the entire year. As such, June was selected for sound propagation modelling to ensure precautionary estimates of distances to received sound level thresholds. Figure F-4 shows the resulting profile, which was used as input to the sound propagation modelling.

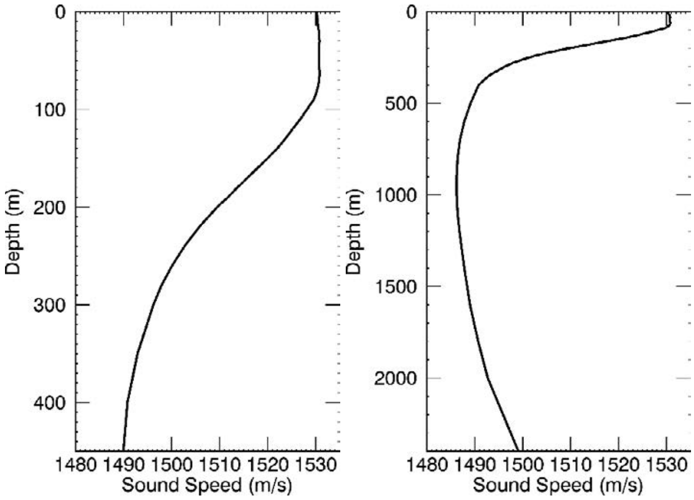

Figure F-4. The modelling sound speed profile corresponding to June: top 450 m (left) and full profile (right) Profiles are calculated from temperature and salinity profiles from *Generalized Digital Environmental Model* V 3.0 (GDEM; Teague et al. 1990, Carnes 2009).

F.3.3. Geoacoustics

As in previous acoustic studies in the area (Duncan 2014), the modelling area was divided into three seabed types (Figure F-5). A silt seabed typical of the continental slope was considered for the majority of the modelling area (Table F-1). A seabed consisting of coarse sand/gravel was used for areas in the vicinity of the reefs (Table F-2). Finally, the reefs were modelled as limestone (Table F-3), using the same equivalent fluid geoacoustic model as in Duncan et al (2014).

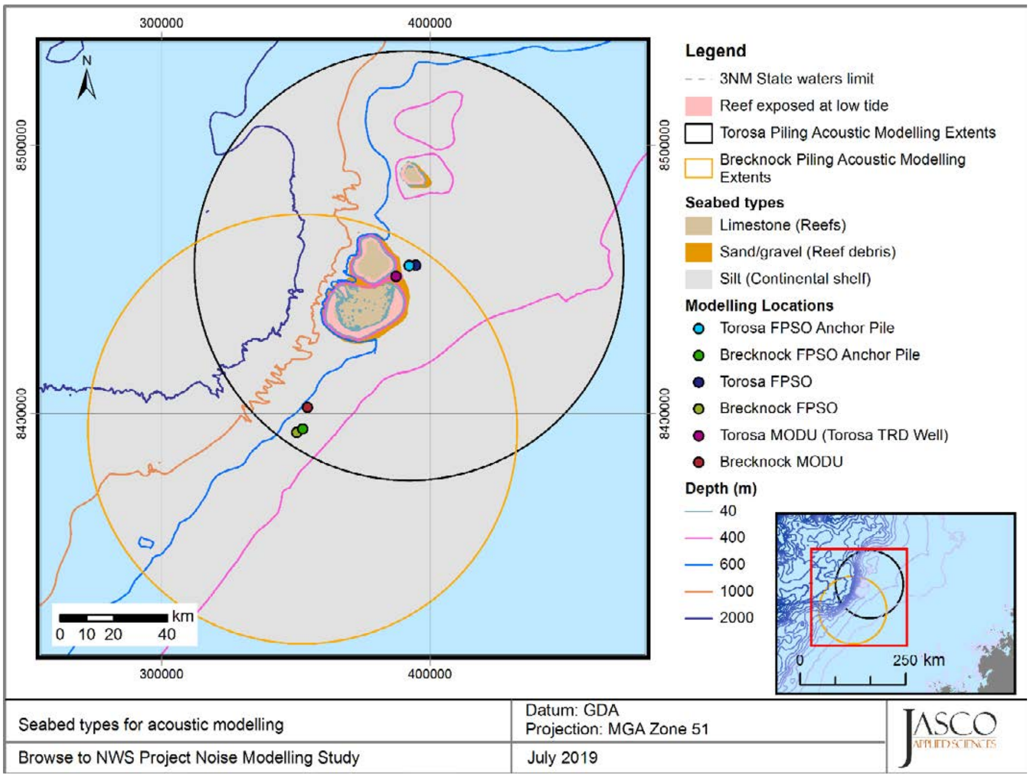

Figure F-5. Geographic boundaries of the seabed types considered in this study , following Duncan et al. (2014).

Table F-1. Continental slope geoacoustic profile. Within each depth range, each parameter varies linearly within the stated range. The compressional wave is the primary wave and the shear wave is the secondary wave.

Depth below seafloor (m)	Material	Density (g/cm³)	Compressional wave		Shear wave	
			Speed (m/s)	Attenuation (dB/λ)	Speed (m/s)	Attenuation (dB/λ)
0–50	Silt	1.70–1.75	1566–1627	1.0	210	1.5
50–100		1.75–1.80	1627–1686			
100–150		1.80–1.85	1686–1742			
150–200		1.85–1.90	1742–1795			
>200		1.90	1795			

Table F-2. Reef debris geoacoustic profile Within each depth range, each parameter varies linearly within the stated range. The compressional wave is the primary wave and the shear wave is the secondary wave.

Depth below seafloor (m)	Material	Density (g/cm^3)	Compressional wave		Shear wave	
			Speed (m/s)	Attenuation (dB/λ)	Speed (m/s)	Attenuation (dB/λ)
0–50	Sand/gravel	1.80–1.85	1714–1782	0.6	300	2.0
50–100		1.85–1.90	1782–1847			
100–150		1.90–1.95	1847–1908			
150–200		1.95–2.00	1908–1967			
>200		2.00	1967			

Table F-3. Reef geoacoustic profile and equivalent fluid modelThe compressional wave is the primary wave and the shear wave is the secondary wave.

Depth below seafloor (m)	Material	Elastic model					Fluid equivalent		
		Density (g/cm^3)	Compressional wave		Shear wave		Density (g/cm^3)	Compressional wave	
			Speed (m/s)	Attenuation (dB/λ)	Speed (m/s)	Attenuation (dB/λ)		Speed (m/s)	Attenuation (dB/λ)
>0	Limestone	2.4	3000	0.1	1500	0.2	2.4	1350	14

F.4. Model Validation Information

Predictions from JASCO's propagation models (MONM, FWRAM, and VSTACK) have been validated against experimental data from a number of underwater acoustic measurement programs conducted by JASCO globally, including the United States and Canadian Artic, Canadian and southern United States waters, Greenland, Russia and Australia (Hannay and Racca 2005, Aerts et al. 2008, Funk et al. 2008, Ireland et al. 2009, O'Neill et al. 2010, Warner et al. 2010, Racca et al. 2012a, Racca et al. 2012b, Matthews and MacGillivray 2013, Martin et al. 2015, Racca et al. 2015, Martin et al. 2017a, Martin et al. 2017b, Warner et al. 2017, MacGillivray 2018, McPherson et al. 2018, McPherson and Martin 2018).

In addition, JASCO has conducted measurement programs associated with a significant number of anthropogenic activities which have included internal validation of the modelling (including McCrodan et al. 2011, Austin and Warner 2012, McPherson and Warner 2012, Austin and Bailey 2013, Austin et al. 2013, Zykov and MacDonnell 2013, Austin 2014, Austin et al. 2015, Austin and Li 2016, Martin and Popper 2016).

Appendix G. Animal Movement and Exposure Modelling

To assess the risk of impacts from exposure, an estimate of received sound levels for the animals in the area during pile driving is required. The sound field may be complex, and the sound received by a moving animal is a function of where the animal is at any given time. The sound source is stationary, and acoustic modelling can be used to predict the 3-D sound field. The location and movement of animals within the sound field, however, is unknown. Realistic animal movement within the sound field can be simulated. Repeated random sampling (Monte Carlo method simulating many animals within the operations area) is used to estimate the sound exposure history of the population of simulated animals during the operation.

Monte Carlo methods provide a heuristic approach for determining the probability distribution function (PDF) of complex situations, such as animals moving in a sound field. The probability of an event's occurrence is determined by the frequency with which it occurs in the simulation. The greater the number of random samples, in this case the more simulated animals (animats), the better the approximation of the PDF. Animats are randomly placed, or seeded, within the simulation boundary at a specified density (animats/km^2). Higher densities provide a finer PDF estimate resolution but require more computational resources. To ensure good representation of the PDF, the animat density is set as high as practical allowing for computation time. The animat density is much higher than the real-world density to ensure good representation of the PDF. The resulting PDF is scaled using the real-world density.

Several models for marine mammal movement have been developed (Ellison et al. 1987, Frankel et al. 2002, Houser 2006). These models use an underlying Markov chain to transition from one state to another based on probabilities determined from measured swimming behaviour. The parameters may represent simple states, such as the speed or heading of the animal, or complex states, such as likelihood of participating in foraging, play, rest, or travel. Attractions and aversions to variables like anthropogenic sounds and different depth ranges can be included in the models.

The JASCO Animal Simulation Model Including Noise Exposure (JASMINE) was based on the open-source Marine Mammal Movement and Behaviour Model (3MB; Houser 2006). JASMINE was used in this study to predict the exposure of virtual animals ('animats') to sound arising from the pile driving activities. Animats were programmed to behave like the species of interest likely to be present in the area of interest. The parameters used for forecasting realistic behaviours (e.g., diving, foraging, aversion, surface times, etc.) were determined and interpreted from marine species studies (e.g., tagging studies) where available, or reasonably extrapolated from related species. An individual animat's modelled sound exposure levels are summed over the total simulation duration, such as 24 h for the current simulation, to determine its total received energy, and then compared to the assumed threshold criteria.

JASMINE uses the same animal movement algorithms as the 3MB model (Houser 2006), but has been extended to be directly compatible with MONM and FWRAM acoustic field predictions, for inclusion of source tracks, and importantly for animats to change behavioural states based on time and space dependent modelled variables such as received levels for aversion behaviour, although aversion was not considered in this study.

G.1. Animal Movement Parameters

JASMINE uses previously measured behaviour to forecast behaviour in new situations and locations. The parameters used for forecasting realistic behaviour are determined (and interpreted) from marine species studies (e.g., tagging studies). Each parameter in the model is described as a probability distribution. When limited or no information is available for a species parameter, a Gaussian or uniform distribution may be chosen for that parameter. For the Gaussian distribution, the user determines the mean and standard deviation of the distribution from which parameter values are drawn. For the uniform distribution, the user determines the maximum and minimum distribution from which parameter values are drawn. When detailed information about the movement and behaviour of a species are available, a user-created distribution vector, including cumulative transition probabilities, may be used (referred to here as a vector model; Houser 2006). Different sets of parameters can be defined for different behaviour states. The probability of an animat starting out in or transitioning into a given behaviour state can in turn be defined in terms of the animat's current behavioural state, depth, and the time of day. In addition, each travel parameter and behavioural state has a termination function that governs how long the parameter value or overall behavioural state persists in simulation.

The parameters used in JASMINE describe animal movement in both the vertical and horizontal planes. The parameters relating to travel in these two planes are briefly described below.

Travel sub-models

- **Direction**– determines an animat's choice of direction in the horizontal plane. Sub-models are available for determining the heading of animats, allowing for movement to range from strongly biased to undirected. A random walk model can be used for behaviours with no directional preference, such as feeding and playing. In a random walk, all bearings are equally likely at each parameter transition time step. A correlated random walk can be used to smooth the changes in bearing by using the current heading as the mean of the distribution from which to draw the next heading. An additional variant of the correlated random walk is available that includes a directional bias for use in situations where animals have a preferred absolute direction, such as migration. A user-defined vector of directional probabilities can also be input to control animat heading. For more detailed discussion of these parameters, see Houser (2006) and Houser and Cross (1999).
- **Travel rate**–defines an animat's rate of travel in the horizontal plane. When combined with vertical speed and dive depth, the dive profile of the animat is produced.

Dive sub-models

- **Ascent rate**–defines an animat's rate of travel in the vertical plane during the ascent portion of a dive.
- **Descent rate**–defines an animat's rate of travel in the vertical plane during the descent portion of a dive.
- **Depth**–defines an animat's maximum dive depth.
- **Reversals**–determines whether multiple vertical excursions occur once an animat reaches the maximum dive depth. This behaviour is used to emulate the foraging behaviour of some marine mammal species at depth. Reversal-specific ascent and descent rates may be specified.
- **Surface interval**–determines the duration an animat spends at, or near, the surface before diving again.

G.1.1. Exposure integration time

The interval over which acoustic exposure (L_E) should be integrated and maximal exposure (L_p) determined is not well defined. Both Southall et al. (2007) and the NMFS (2018) recommend a 24 h baseline accumulation period, but state that there may be situations where this is not appropriate (e.g., a high-level source and confined population). Resetting the integration after 24 h can lead to overestimating the number of individual animals exposed because individuals can be counted multiple times during an operation. The type of animal movement engine used in this study simulates realistic movement using swimming behaviour collected over relatively short periods (hours to days) and does not include large-scale movement such as migratory circulation patterns. For this study, a single day was modelled.

Ideally, a simulation area is large enough to encompass the entire range of a population so that any animal that could approach the pile driving site during an operation is included. However, there are limits to the simulation area, and computational overhead increases with area. For practical reasons, the simulation area is limited in this analysis to a maximum distance from the piling operation. In the simulation, every animat that reaches a border is replaced by another animat entering at the opposing border—e.g., an animat crossing the northern border of the simulation is replaced by one entering the southern border at the same longitude. When this action places the animat in an inappropriate water depth, the animat is randomly placed on the map at a depth suited to its species definition. The exposures of all animats (including those leaving the simulation and those entering) are kept for analysis. This approach maintains a consistent animat density and allows for longer integration periods with finite simulation areas.

G.1.2. Seeding density and scaling

The exposure criteria for impulsive sounds were used to determine the number of animats exceeding exposure thresholds. To generate statistically reliable probability density functions, all simulations were seeded with a specific animat density over the entire simulation area. To evaluate potential injury (PTS), TTS, or behavioural disturbance, threshold exceedance was determined in a 24 h time window. From the numbers of animats exceeding threshold, the numbers of individual pygmy blue whales and green turtles predicted to exceed threshold were determined by scaling the animat results by the ratio of local real-world density to modelling density.

G.2. Pygmy Blue Whale Species-Specific Details

Table G-1. *Foraging pygmy blue whales*: Data values and references input in JASMINE to create diving behaviour (number values represent means [standard deviations] unless otherwise indicated).

Behaviour	Variable	Value	Reference

1. Introduction

This report is an addendum to McPherson et al. (2019), and presents:

- Additional modelling scenarios:
    - The additional modelled scenarios consider both Floating Production Storage and Offloading (FPSO) facilities during offtake along with operations of a Mobile Offshore Drilling Unit (MODU) under dynamic positioning at either the Torosa TRD well or Brecknock. The FPSO operational noise during offtake, includes the FPSO under DP, an Offshore Support Vessel (OSV) near each FPSO (presented in isolation also) and a noiseless condensate tanker.
- Discussion of the interaction between impulsive and continuous sources from an acoustic modelling for impact assessment perspective.
- Calculations of the areas within relevant threshold isopleths for the static acoustic modelling sound fields were calculated from the area encompassed by the shape file representing the isopleths.
- Areas within specific threshold isopleths from the static sound field modelling results presented in McPherson et al. (2019) and this addendum. Additionally, the area of the overlap between considered Biologically Important Areas (BIAs) and the relevant isopleths is also calculated.
- For the assessment of turtle exposure through animal movement and exposure modelling, considering an additional BIA, that for the Department of Environment and Energy (DoEE) Green Turtle Inter-nesting Buffer located at Scott Reef – Sandy Islet.

The geographic coordinates for the modelled sites are provided in Table 1 and an overview of the modelling area is shown in Figure 1.

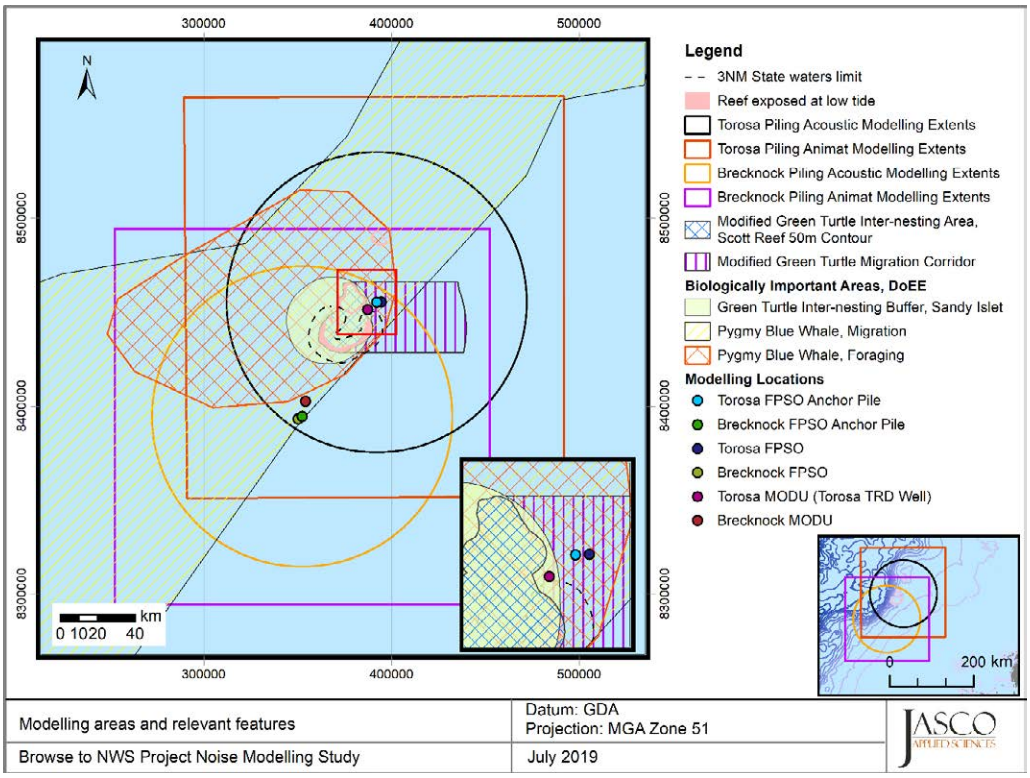

Figure 1. Overview of the modelled area and local features.

Table 1. Location details for the modelled sites.

2. Methods

In addition to the methods presented in McPherson et al. (2019), the methodology for the calculations of ensonified and exposed areas, both in their own right and overlapping relevant BIA’s, and the consideration of an additional green turtle BIA and an alternative number of individuals, is outlined in this addendum report.

2.1. Exposed Areas

The areas within relevant threshold isopleths for the static acoustic modelling sound fields were calculated from the area encompassed by the shape file representing the isopleths. These areas can be combined to create a simplistic representation of the area within which a threshold is exceeded to assist with the impact assessment.

For the animal movement and exposure modelling, a key output was the 95th percentile ranges (P_{95}), or the range within which 95% of the exposure exceedances. This range was converted into an area ($\pi^*(P_{95})^2$).

To calculate the overlap between the area within a threshold isopleth or P_{95} area of a pygmy blue whale or green turtle relevant BIA, the two features were mapped in Global Mapper (Global Mapper 2019) and the overlapping area calculated.

2.2. Animal Movement and Exposure Modelling

2.2.1. Assessment areas

Two areas of interest are defined for inter-nesting green turtles:(1) a modified Biologically Important Area (BIA) defined by the 50 m contour around North and South Scott Reef, including a corridor connecting the two reefs, and (2) the DoEE-defined inter-nesting BIA boundary around Scott Reef.

Figures 2 and 3 show maps of both of the BIAs for inter-nesting green turtles in relation to both the Torosa and Brecknock piling locations. Both maps also show the extents of the modelling and animat simulation area. To account for the difference between the animat simulation area and the BIAs, the final exposure estimates are scaled by the ratio of the clipped BIA relative to the simulation area.

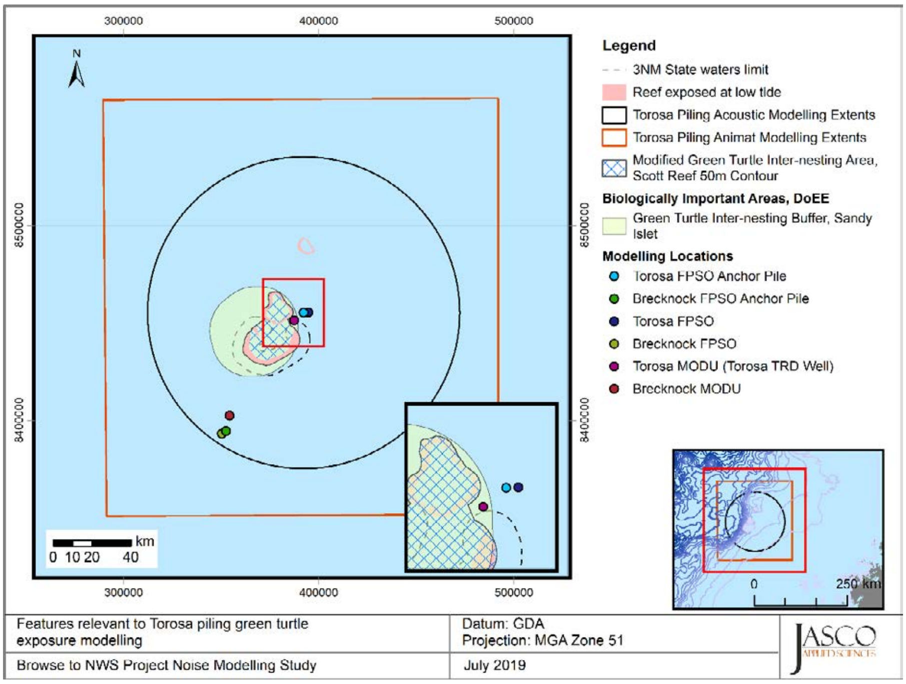

Figure 2. *Torosa:* Map of green turtle exposure modelling features, including modified BIAs for inter-nesting and migrating green turtles, along with extents for acoustic propagation modelling and animat modelling.

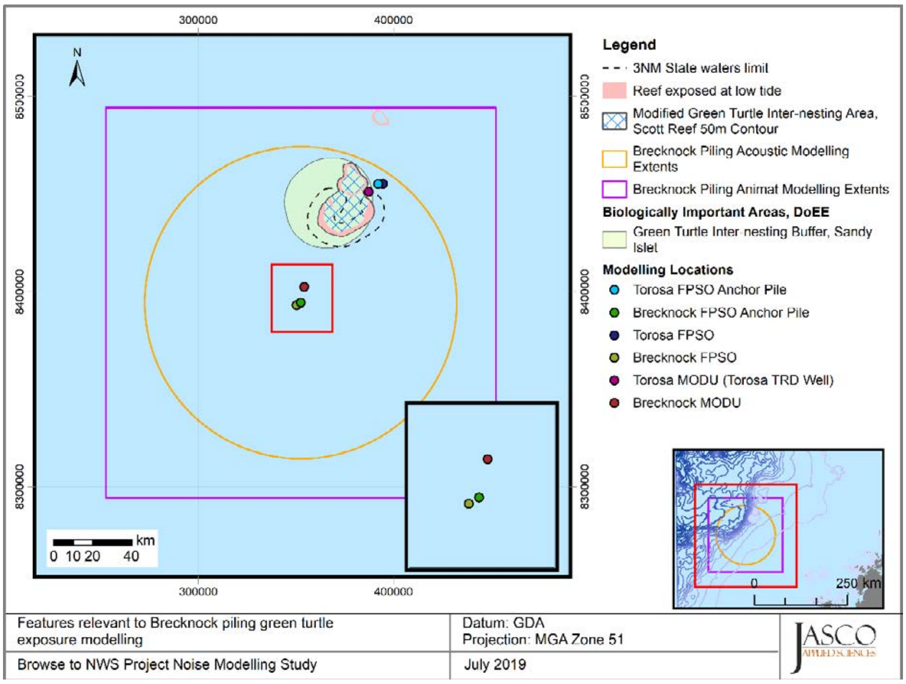

Figure 3. *Brecknock:* Map of green turtle exposure modelling features, including modified BIAs for inter-nesting and migrating green turtles, along with extents for acoustic propagation modelling and animat modelling.

2.2.2. Methodology

The exposure criteria for impulsive sounds (described in Section 2, McPherson et al. (2019)) were used to determine the number of animats exceeding thresholds. To evaluate potential injury (PTS), TTS, and behavioural disturbance, exposure results were summed over the driving of a single pile, which represents the exposure over 24 h, as only one pile will be driven per day.

Model simulations were run with animat seeding densities of 15 animats/km^2 for pygmy blue whales and 15 animats/km^2 green turtles to generate a statistically reliable probability density function (PDF) for each species. Seeding densities need to be high enough to adequately sample the underlying sound exposure PDF. Typically, for longer duration simulations (7-14 days), a seeding density of 0.5 animats/km^2 is sufficient. However, in this case, where the active duration of the pile driving is less than 80 minutes within 24 hours (78.5 or 80 minutes, IH S-600 hammer, Tables 16 and 17, McPherson et al. (2019)), the simulated density must be increased substantially to provide a comparably reliable sampling of the underlying PDF. A statistically equivalent result could also be accomplished by running several independent simulations at a lower seeding density; however, this is computationally less efficient. The number of simulated animats exposed above relevant thresholds can then be scaled by the ratio of the real-world density to the seeded animat density to convert to an estimate of the number of individual animals impacted.

The distribution of ranges of exposed animats was used to estimate the 95th percentile ranges at which the animats were exposed above threshold. Within the 95th percentile range, there are generally some proportion of animats that did not exceed threshold criteria.

The proposed number of individual green turtles in McPherson et al. (2019) was 1162, or a density of 1.79 turtles/km^2 within an inter-nesting area defined by the 50 m bathymetry around North and South Scott Reef, referred to as the ‘Modified Green Turtle Inter-nesting Area, Scott Reef 50 m Contour’. This addendum considers the possibility of 5000 individuals within this modified inter-nesting area.

3.1.3. Animal Movement and Exposure Modelling

Summaries of the animat modelling results at Torosa for inter-nesting green turtles with 1162 or 5000 individuals are provided in Table 9.

Table 9. *Torosa*: Summary of animat simulation results for inter-nesting turtles. Includes the distances to acoustic modelling thresholds (km), the 95th percentile exposure ranges (km), and the number of real-world individuals exposed above threshold. Acoustic modelling results are presented in McPherson et al. (2019).

† Threshold for marine mammal behavioural response to continuous noise (NMFS 2014).

4. Discussion

This addendum presents exposure areas for isopleths representing specific thresholds from the static sound field modelling results and scenarios originally presented in McPherson et al. (2019). Two additional aggregate scenarios are presented in this addendum. The presented areas are associated with noise exposures and thresholds both continuous and impulsive noise sources respectively.

This study presents areas of exposure associated with continuous noise source underwater sound levels from scenarios that include the operations of a Mobile Offshore Drilling Unit (MODU), FPSOs with and without DP operating, an OSV near each FPSO, and Offtake operations including an FPSO under DP, a noiseless condensate tanker and an OSV for locations at Torosa and Brecknock.

Areas of exposure associated with impulsive noise sources from scenarios that include impact driving of subsea piles to anchor the Torosa and Brecknock FPSO facility turret are also presented.

The areas presented in both this addendum and McPherson et al. (2019) represent the areas from the considered modelling scenarios and specific sources. Depending upon the metric and threshold, these areas can be combined to create a simplistic representation of the area within which a threshold is exceeded to assist with the impact assessment.

4.1. Cumulative Scenarios from Impulsive and Continuous Sources

4.1.1. Areas associated with PTS and TTS thresholds

Considering the different characterises of continuous versus impulsive sources, the adopted noise exposure criteria NMFS (2018) considers several received level thresholds and two metrics to assess the effect of noise on marine mammals of the considered sources. One set of metrics and thresholds apply to continuous (non-pulsed) noise sources and a different set apply to impulsive sources. Considering this, it is not possible to present distances to thresholds for cumulative scenarios that contain both pile driving and vessel noise (impulsive and continuous sources). The total exposed area for marine mammal PTS or TTS could be calculated considering the individual exposure areas to determine the maximum exposed area for a cumulative scenario with both continuous and impulsive sources; however this is likely an unduly simplistic and un-assessable given the NMFS (2018) exposure criteria. It also depends upon the time period the different sources under consideration are operational.

Furthermore, the NMFS (2018) criteria were developed considering impulsive source and continuous sources separately, it is therefore appropriate to assess impulsive and continuous (pile driving and vessel noise) separately. No criteria exist for received levels with impulsive and continuous character and it is not currently known what the effect of a received levels with impulsive and continuous character would have on marine mammal PTS and TTS thresholds and spatial extent, if any.

4.1.2. Behavioural Areas

Similar to the points above in regard to PTS and TTS thresholds, an aggregate area considering the behavioural response to sound could be calculated from pile driving and vessel operations. However, ability to assess the source specific spatial extent of behavioural thresholds would be lost in an aggregate impulsive and continuous scenario because the threshold is associated with different sound levels.

EXECUTIVE SUMMARY

RPS was commissioned by Woodside Energy Ltd (Woodside) to undertake a marine dispersion modelling study of proposed water discharges from the proposed Browse Joint Venture (BJV) Floating Production Storage and Offloading (FPSO) facilities. The Browse hydrocarbon resource is located in the Brecknock, Calliance and Torosa reservoirs located approximately 425 km north of Broome and approximately 290 km off the Kimberley coastline.

The BJV propose to develop the Browse resource using two FPSO facilities with up to 1,100 million standard cubic feet per day (MMscf/d) export capacity (annual daily average). The proposed FPSOs will be supplied by a subsea production system and will export gas to existing North West Shelf (NWS) Project infrastructure via a ~85 km spur line and a ~900 km Browse Trunkline (BTL), which will tie in near the North Rankin Complex (NRC).

Woodside Energy Ltd (Woodside) is Operator for and on behalf of the BJV: Woodside Browse Pty Ltd, Shell Australia Pty Ltd (Shell), BP Developments Australia Pty Ltd (BP), Japan Australia LNG (MIMI Browse) Pty Ltd (MIMI) and PetroChina International Investment (Australia) Pty Ltd (PetroChina).

The proposed Browse to NWS Project involves the processing of hydrocarbons and as a result will produce cooling water (CW) and produced water (PW). In situ hydrostatic pressure testing may be performed following installation of the BTL/inter-field spur line. If required, this will occur during commissioning. Hydrotesting will require hydrotest fluid to be introduced and left in situ to protect the infrastructure from corrosion. Hydrotest fluids will be directly discharged to sea from the Pipeline End Terminals (PLETs).

The principal aim of the study was to quantify the possible extents of the near-field and far-field mixing zones based on:

- The predicted dilution levels for chlorine in the CW discharge and the temperature differential between the discharge and the ambient receiving water;
- The predicted dilution levels for total oil (including benzene, toluene, ethylbenzene and xylene; BTEX), mercury and monoethylene glycol (MEG) in the PW discharge;
- The predicted dilution levels for biocide in the hydrotest discharge.

This will indicate the concentrations of these constituents and the temperature of the plume at the limits of the mixing zones (i.e. the predictions of dilution or cooling relative to the source characteristics).

To accurately determine the dilution of the discharges and the total potential area of influence, the effect of near-field mixing needs to be considered first, followed by an investigation of the far-field mixing performance. Different modelling approaches are required for calculating near-field and far-field dilutions due to the differing hydrodynamic scales.

To assess the rate of mixing of the chlorine in the CW stream from the Torosa FPSO, dispersion modelling was carried out for a flow rate of 720,000 m^3/d at a discharge depth of 12 m below the water surface.

To assess the rate of mixing of the total oil, mercury and MEG in the PW stream from the Torosa FPSO, dispersion modelling was carried out for flow rates of 5,723 m^3/d and 490 m^3/d at a discharge depth of 14 m below the water surface.

To assess the rate of mixing of the biocide in the hydrotest stream from each PLET, dispersion modelling was carried out for a flow rate of 25 m^3/min (36,000 m^3/d) at three discharge locations in water depths of 117 m, 461 m and 539 m.

The potential area that may be influenced by the discharge streams was assessed for three distinct seasons: (i) summer (December to February); (ii) the transitional periods (March and September to November); and (iii) winter (April to August). An annualised aggregation of outcomes was also assembled.

The main findings of the study are as follows:

Near-Field Modelling

Cooling Water Discharges

- The results show that due to the momentum of the discharge a turbulent mixing zone is created in the immediate vicinity of the discharge point, which is 12 m below the water surface (Case C). Medium and strong currents are shown to increase the extent of the turbulent mixing zone. Following this initial mixing, the positively buoyant plume is predicted to rise in the water column.
- The plume is predicted to plunge up to 16 m below the sea surface in all seasons.
- Increased ambient current strengths are shown to increase the horizontal distance travelled by the plume from the discharge point.
- The maximum horizontal distance travelled by the plume under annualised average current speeds is predicted as 37.8 m.
- The maximum diameter of the plume at the end of the near-field zone is predicted as 15.2 m.
- For all seasons, the primary factor influencing dilution of the plume is the strength of the ambient current. Weak currents allow the plume to reach the trapping depth (at which the predictions of dispersion are halted due to the plume reaching equilibrium with the ambient receiving water) closer to the discharge point, which slows the rate of dilution.
- The average dilution levels of the plume upon reaching the trapping depth under annualised average current speeds are predicted to be 1:13.5 for Case C. Additionally, the minimum dilution levels of the plume (i.e. dilution of the plume centreline) upon encountering the trapping depth under annualised average current speeds are predicted to be 1:6.3 for Case C.
- The predictions of dilution rely on the persistence of current speed and direction over time and do not account for any build-up of plume concentrations due to slack currents or current reversals.

Produced Water Discharges

- The results show that due to the momentum of the discharges a turbulent mixing zone is created in the immediate vicinity of the discharge point, which is 14 m below the water surface (Cases P and M). Medium and strong currents are shown to increase the extent of the turbulent mixing zone. Following this initial mixing, the positively buoyant plumes are predicted to rise in the water column.
- For Cases P and M, the plume is predicted to rise towards the water surface after the momentum of the initial discharge is lost.
- Increased ambient current strengths are shown to increase the horizontal distance travelled by the plume from the discharge point.
- For both discharges, the maximum horizontal distance travelled by the plume under annualised average current speeds is predicted as 20.2 m.
- For both discharges, the maximum diameter of the plume at the end of the near-field zone is predicted as 11.7 m.
- For all combinations of discharge case and season, the primary factor influencing dilution of the plume is the strength of the ambient current. Weak currents allow the plume to reach the trapping depth (at which the predictions of dispersion are halted due to the plume reaching equilibrium with the ambient receiving water) closer to the discharge point, which slows the rate of dilution.

- The average dilution levels of the plume upon reaching the trapping depth under annualised average current speeds are predicted to be 1:204 for Case P and 1:1,222 for Case M. Additionally, the minimum dilution levels of the plume (i.e. dilution of the plume centreline) upon encountering the trapping depth under annualised average current speeds are predicted to be 1:70 for Case P and 1:323 for Case M.

- The predictions of dilution rely on the persistence of current speed and direction over time and do not account for any build-up of plume concentrations due to slack currents or current reversals.

Hydrotest Discharges

- The results show that due to the momentum of the discharges a turbulent mixing zone is created in the immediate vicinity of the discharge points, which are 117 m (Case H1), 461 m (Cases H2 and H3b) and 539 m (Case H3a) below the water surface. Following this initial mixing, the near neutrally buoyant plumes are predicted to travel laterally in the water column.

- Increased ambient current strengths are shown to increase the horizontal distance travelled by the plume from the discharge point.

- For all discharges, the maximum horizontal distance travelled by the plume under annualised average current speeds is predicted as being in the range 50-77 m.

- For all discharges, the maximum diameter of the plume at the end of the near-field zone is predicted as being in the range 16-24 m.

- For all combinations of discharge case and season, the primary factor influencing dilution of the plume is the strength of the ambient current. Weak currents allow the plume to reach the trapping depth (at which the predictions of dispersion are halted due to the plume reaching equilibrium with the ambient receiving water) closer to the discharge point, which slows the rate of dilution.

- The average dilution levels of the plume upon reaching the trapping depth under annualised average current speeds are predicted to be 1:111 for Case H1, 1:166 for Case H2, 1:172 for Case H3a and 1:166 for Case H3b. Additionally, the minimum dilution levels of the plume (i.e. dilution of the plume centreline) upon encountering the trapping depth under annualised average current speeds are predicted to be 1:41 for Case H1, 1:62 for Case H2, 1:65 for Case H3a and 1:62 for Case H3b.

- The predictions of dilution rely on the persistence of current speed and direction over time and do not account for any build-up of plume concentrations due to slack currents or current reversals.

Far-Field Modelling

Cooling Water Discharges

- Instantaneous concentrations (based on a 60-second model time step) are considered when calculating dilution contours.

- The minimum level of dilution achieved at or within the Scott Reef receptor at the 95th percentile in any season is predicted to be 1:125 for Case C.

- For Case C, annualised results show dilution to reach an example level of 1:100 is achieved within an area of influence extending up to 4.2 km at the 95th percentile. The discharged plumes are predicted to travel predominantly along a north-northwest/south-southeast axis throughout the year, which is broadly parallel to the Scott Reef receptor boundary.

- For Case C, annualised results show the area of exposure defined by the 1:100 dilution contour is predicted to reach a maximum value of 3.7 km^2 at the 95th percentile.

- The maximum depth reached by the discharge across all seasons is predicted as 20 m for Case C.

- Considering the relative rates of acclimation of the plume characteristics with the ambient water, the limiting factor for the plume's area of influence is likely to be defined by its chlorine constituent rather than its temperature.

- An example 3 °C plume-ambient temperature differential is forecast to be met within 120 m at the 95th percentile across all seasons.

Produced Water Discharges

- Instantaneous concentrations (based on a 60-second model time step) are considered when calculating dilution contours.

- The minimum levels of dilution achieved at or within the Scott Reef receptor at the 95th percentile in any season are predicted to be 1:1,507 for Case P and 1:17,674 for Case M.

- For Case P, annualised results show dilution to reach an example level of 1:300 is achieved within an area of influence extending up to 0.9 km at the 95th percentile. The discharged plumes are predicted to travel predominantly along a north-northwest/south-southeast axis throughout the year, which is broadly parallel to the Scott Reef receptor boundary, with trajectories to the south-southeast forecast to be longer.

- For Case P, annualised results show the area of exposure defined by the 1:300 dilution contour is predicted to reach a maximum value of 0.7 km^2 at the 95th percentile.

- The maximum depth reached by the discharge across all seasons is predicted as 19 m for Case P.

Hydrotest Discharges

- Concentrations calculated following application of a rolling 48-hour median to the instantaneous data are considered when calculating dilution contours.

- The minimum levels of dilution achieved at or within the nearest receptor at the 95th percentile in any season are predicted to be >>1:20,000 for Case H1 (Rankin Bank), 1:4,440 for Case H2 (Scott Reef), >1:20,000 for Case H3a (Scott Reef) and 1:2,711 for Case H3b (Scott Reef).

- For Cases H1, H2, H3a and H3b, annualised results show dilution to reach an example level of 1:10,000 is achieved within an area of influence extended up to 16.1 km, 12.5 km, 23.4 km and 8.2 km, respectively, at the 95th percentile. The predominant plume travel directions throughout the year are forecast to be south-westerly (Case H1), along a north-northwest/south-southeast axis (Cases H2 and H3a) and along a north-east/south-west axis (Case H3a).

- For Cases H1, H2, H3a and H3b, annualised results show the area of exposure defined by the 1:10,000 dilution contour is predicted to reach a maximum of 79.2 km^2, 87.1 km^2, 89.4 km^2 and 40.8 km^2, respectively, at the 95th percentile.

Key Observations

Cooling Water Discharges

- The discharge will be initially positively buoyant and will rise in the water column, and may resurface in the vicinity of the discharge point prior to acclimation with ambient receiving water conditions.

- At the 95th percentile, plumes for Case C are not expected to reach the Scott Reef 3 nm State water boundary at dilution levels less than 1:125 in any season.

- At the 95th percentile, temperature acclimation of the plume with ambient waters is expected to occur within 120 m of the discharge point in any season and plume temperature will not be a relevant factor at the Scott Reef 3 nm State water boundary.

Produced Water Discharges

- At the 95th percentile, plumes are not expected to reach the Scott Reef 3 nm State water boundary at dilution levels less than 1:1,507 for Case P and 1:17,674 for Case M in any season.

Hydrotest Discharges

- Due to significant variations in the magnitude and directionality of the hindcast currents at each location where potential discharges will occur, predicted outcomes are markedly different.
- Transport patterns will reflect the predominant drift current trajectories at each location, with tidal movements a particularly important driver of dispersion for the deeper discharges. Greater variability in current trajectories is expected near the water surface due to the influence of wind, but, because the plumes are discharged at the seabed and are not positively buoyant, they will not experience these variations.
- At the 95th percentile, plumes are not expected to reach the Scott Reef 3 nm State water boundary at dilution levels less than 1:4,440 for Case H2, 1:20,000 for Case H3a and 1:2,711 for Case H3b in any season. For Case H1, the dilution level of any plumes that may reach Rankin Bank is expected to be significantly greater than 1:20,000.

1 INTRODUCTION

1.1 Background

RPS was commissioned by Woodside Energy Ltd (Woodside) to undertake a marine dispersion modelling study of proposed water discharges from the proposed Browse Joint Venture (BJV) Floating Production Storage and Offloading (FPSO) facilities. The Browse hydrocarbon resource is located in the Brecknock, Calliance and Torosa reservoirs located approximately 425 km north of Broome and approximately 290 km off the Kimberley coastline.

The BJV propose to develop the Browse resource using two FPSO facilities with up to 1,100 million standard cubic feet per day (MMscf/d) export capacity (annual daily average). The proposed FPSOs will be supplied by a subsea production system and will export gas to existing North West Shelf (NWS) Project infrastructure via a ~85 km spur line and a ~900 km Browse Trunkline (BTL), which will tie in near the North Rankin Complex (NRC).

Woodside Energy Ltd (Woodside) is Operator for and on behalf of the BJV: Woodside Browse Pty Ltd, Shell Australia Pty Ltd (Shell), BP Developments Australia Pty Ltd (BP), Japan Australia LNG (MIMI Browse) Pty Ltd (MIMI) and PetroChina International Investment (Australia) Pty Ltd (PetroChina).

The proposed Browse to NWS Project involves the processing of hydrocarbons and as a result will produce cooling water (CW) and produced water (PW). In situ hydrostatic pressure testing may be performed following installation of the BTL/inter-field spur line. If required, this will occur during commissioning. Hydrotesting will require hydrotest fluid to be introduced and left in situ to protect the infrastructure from corrosion. Hydrotest fluids will be directly discharged to sea from the Pipeline End Terminals (PLETs).

The principal aim of the study was to quantify the possible extents of the near-field and far-field mixing zones based on:

- The predicted dilution levels for chlorine in the CW discharge and the temperature differential between the discharge and the ambient receiving water;
- The predicted dilution levels for total oil (including benzene, toluene, ethylbenzene and xylene; BTEX), mercury and monoethylene glycol (MEG) in the PW discharge;
- The predicted dilution levels for biocide in the hydrotest discharge.

This will indicate the concentrations of these constituents and the temperature of the plume at the limits of the mixing zones (i.e. the predictions of dilution or cooling relative to the source characteristics).

To accurately determine the dilution of the discharges and the total potential area of influence, the effect of near-field mixing needs to be considered first, followed by an investigation of the far-field mixing performance. Different modelling approaches are required for calculating near-field and far-field dilutions due to the differing hydrodynamic scales.

To assess the rate of mixing of the chlorine in the CW stream from the Torosa FPSO (location shown in Table 1.1 and Figure 1.1), dispersion modelling was carried out for a flow rate of 720,000 m^3/d at a discharge depth of 12 m below the water surface.

To assess the rate of mixing of the total oil, mercury and MEG in the PW stream from the Torosa FPSO, dispersion modelling was carried out for flow rates of 5,723 m^3/d and 490 m^3/d at a discharge depth of 14 m below the water surface.

To assess the rate of mixing of the biocide in the hydrotest stream from each PLET (locations shown in Table 1.1 and Figure 1.1), dispersion modelling was carried out for a flow rate of 25 m^3/min (36,000 m^3/d) at three discharge locations in water depths of 117 m, 461 m and 539 m.

The potential area that may be influenced by the discharge streams was assessed for three distinct seasons: (i) summer (December to February); (ii) the transitional periods (March and September to November); and (iii) winter (April to August). An annualised aggregation of outcomes was also assembled.

All discharge characteristics used as input to the modelling are specified in the Model Input Form for this study (Woodside, 2019).

Table 1.1 Locations of the proposed Torosa FPSO and PLETs used as the release sites for the dispersion modelling assessment.

Release Site	Latitude (S)	Longitude (E)	Water Depth (m)
Torosa FPSO	13° 58' 15.06"	122° 01' 28.53"	481
Torosa PLET	13° 58' 41.70"	122° 01' 26.76"	461
Brecknock/Calliance PLET	14° 32' 21.92"	121° 37' 34.23"	539
NRC Tie-In PLET	19° 36' 41.37"	116° 10' 23.53"	117

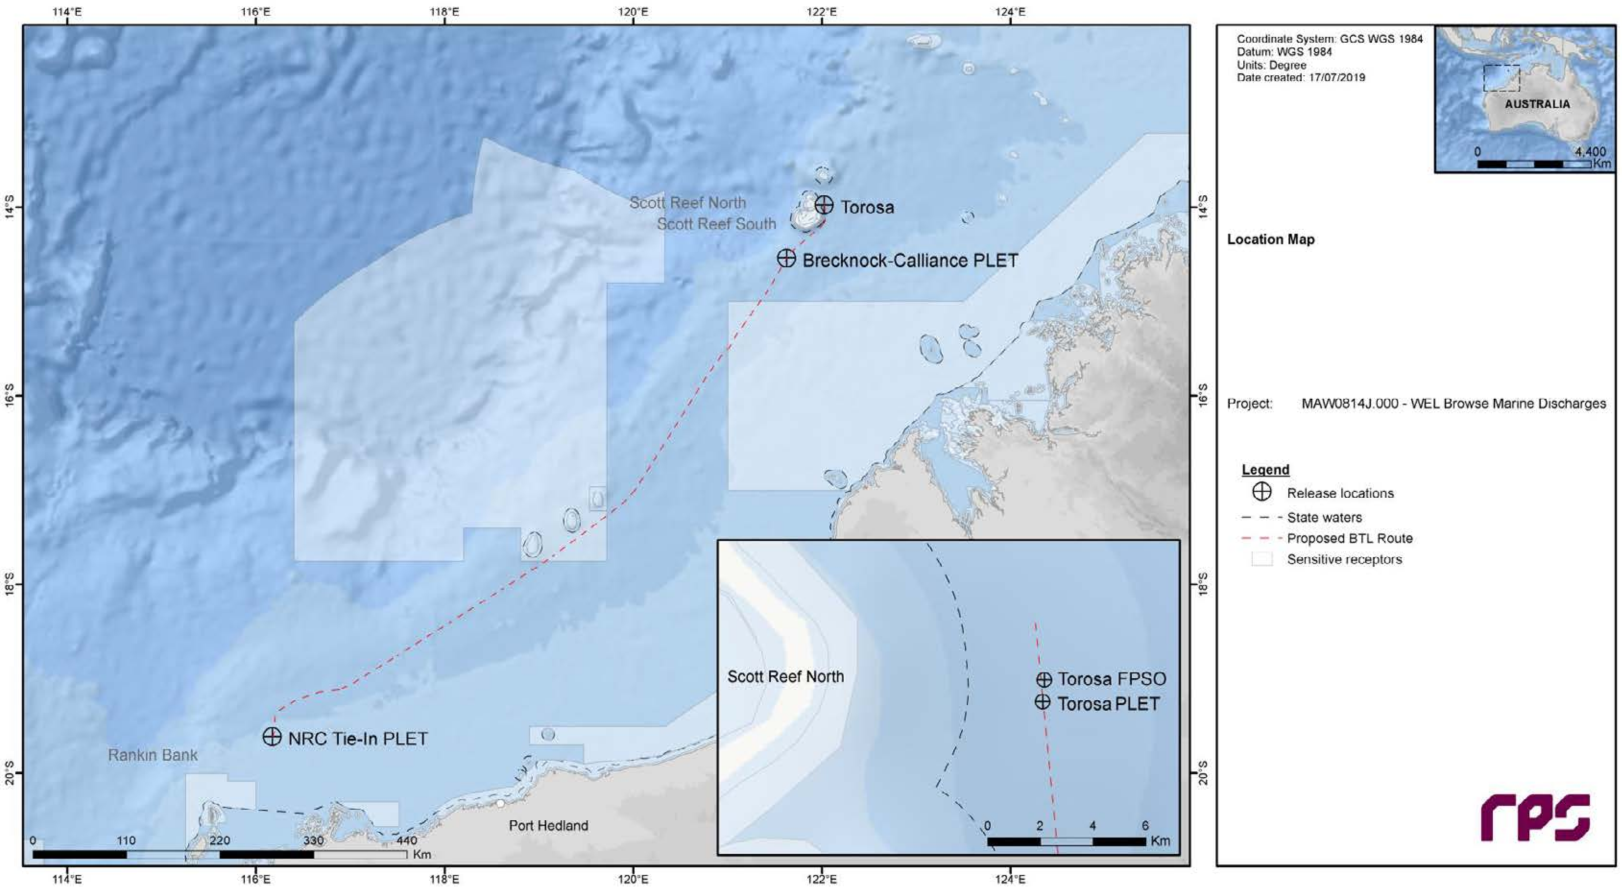

Figure 1.1 Locations of the proposed Torosa FPSO and PLETs, on the North West Shelf and in proximity to Scott Reef, off the Kimberley Coast of Western Australia.

1.2 Modelling Scope

The physical mixing of the CW, PW and hydrotest plumes was first investigated for the near-field mixing zone. The limits of the near-field mixing zone are defined by the area where the levels of mixing and dilution are controlled by a plume's initial jet momentum and the buoyancy flux, resulting from density differences between the plume and the receiving water. When the plume encounters a boundary such as the water surface, near-field mixing is complete. At this point, the plume is considered to enter the far-field mixing zone.

The scope of the modelling included the following components:

- Collation of a suitable three-dimensional, spatially-varying current data set surrounding the Torosa FPSO and NRC tie-in, Torosa and Brecknock/Calliance PLET locations for a ten-year (2006-2015) hindcast period. The current data set included the combined influence of drift and tidal currents and was suitably long as to be indicative of interannual variability in ocean currents. The current data set was validated against metocean data collected in the Browse project area, and also against independent tidal predictions at many locations within the model domain including the NRC area.

- Derivation of statistical distributions for the current speed and directions for use in the near-field modelling. Analyses included percentile distributions and development of current roses. This analysis was important to ensure that current data samples applied in the dispersion model were statistically representative.

- Collation of seasonally-varying vertical water density profiles at the Torosa FPSO and NRC tie-in, Torosa and Brecknock/Calliance PLET locations for use as input to the dispersion models.

- Near-field modelling conducted for each unique discharge to assess the initial mixing of the discharge due to turbulence and subsequent entrainment of ambient water. This modelling was conducted at high spatial and temporal resolution (scales of metres and seconds, respectively).

- Outcomes from the near-field modelling included estimates of the width, shape and orientation of the plumes, and resulting constituent concentrations and dilutions, for each discharge at a range of incident current speeds.

- Establishment of a far-field dispersion model to repeatedly assess discharge scenarios under different sample conditions, with each sample represented by a unique time sequence of current flow, chosen at random from the time series of current data.

- Analysis of the results of all simulations to quantify, by return frequency, the potential extent and shape of the mixing zone.

2 MODELLING METHODS

2.1 Near-Field Modelling

2.1.1 Overview

Numerical modelling was applied to quantify the area of influence of CW, PW and hydrotest water discharges, in terms of the distribution of the maximum constituent concentrations that might occur with distance from the source given defined discharge configurations, source concentrations, and the distribution of the metocean conditions affecting the discharge location.

The dispersion of the CW, PW and hydrotest discharges will depend, initially, on the geometry and hydrodynamics of the discharges themselves, where the induced momentum and buoyancy effects dominate over background processes. This region is generally referred to as the near-field zone and is characterised by variations over short time and space scales. As the discharges mix with the ambient waters, the momentum and buoyancy signatures are eroded, and the background – or ambient – processes become dominant.

The shape and orientation of the discharged water plumes, and hence the distribution and dilution rate of the plume, will vary significantly with natural variation in prevailing water currents. Therefore, to best calculate the likely outcomes of the discharges, it is necessary to simulate discharge under a statistically representative range of current speeds representative of the Torosa FPSO and NRC tie-in, Torosa and Brecknock/Calliance PLET locations.

2.1.2 Description of Near-Field Model: Updated Merge

The near-field mixing and dispersion of the water discharge was simulated using the Updated Merge (UM3) flow model. The UM3 model is a three-dimensional Lagrangian steady-state plume trajectory model designed for simulating single and multiple-port submerged discharges in a range of configurations, available within the Visual Plumes modelling package provided by the United States Environmental Protection Agency (Frick *et al.*, 2003). The UM3 model was selected because it has been extensively tested for various discharges and found to predict observed dilutions more accurately (Roberts & Tian, 2004) than other near-field models (i.e. RSB and CORMIX).

In the UM3 model, the equations for conservation of mass, momentum, and energy are solved at each time step, giving the dilution along the plume trajectory. To determine the change of each term, UM3 follows the shear (or Taylor) entrainment hypothesis and the projected-area-entrainment (PAE) hypothesis, which quantifies forced entrainment in the presence of a background ocean current. The flows begin as round buoyant jets and can merge to a plane buoyant jet (Carvalho *et al.*, 2002). Model output consists of plume characteristics including centreline dilution, rise-rate, width, centreline height and plume diameter. Dilution is reported as the “effective dilution”, the ratio of the initial concentration to the concentration of the plume at a given point, following Baumgartner *et al.* (1994).

The near-field zone ends where the discharged plume reaches a physical boundary or assumes the same density as the ambient water.

Figure 2.1 and Figure 2.2 show conceptual diagrams of the dispersion and fates of positively and negatively buoyant discharges, respectively, and the idealised representation of the discharge phases.

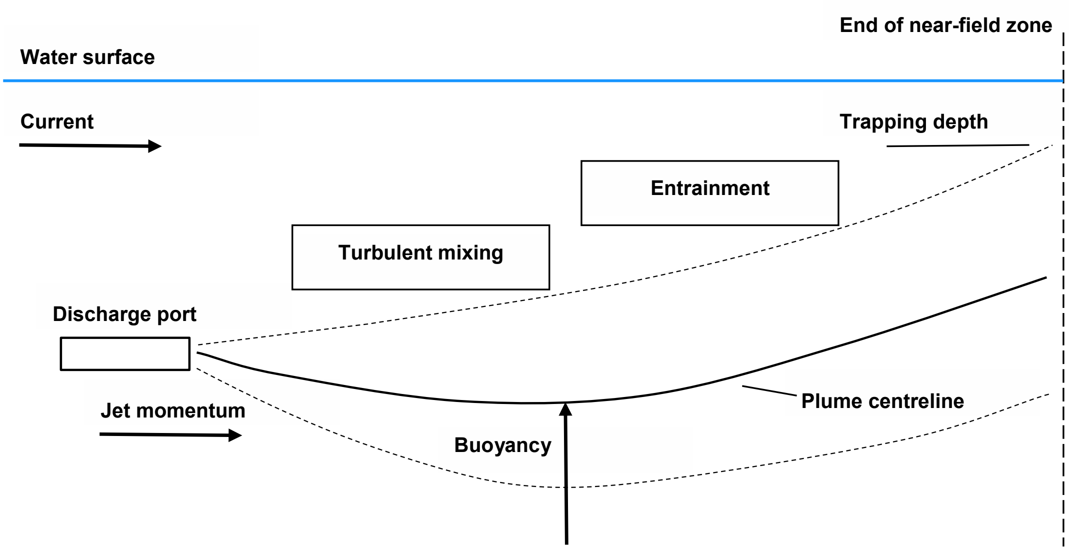

Figure 2.1 Conceptual diagram showing the general behaviour of a positively buoyant discharge.

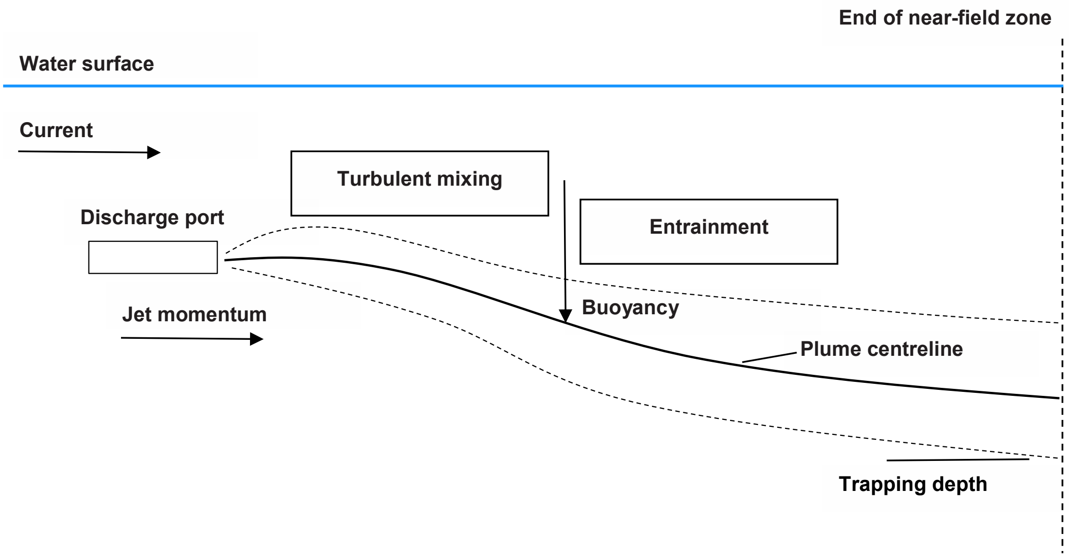

Figure 2.2 Conceptual diagram showing the general behaviour of a negatively buoyant discharge.

2.1.3 Setup of Near-Field Model

2.1.3.1 Discharge Characteristics

The CW discharge characteristics for Case C are summarised in Table 2.1. Case C represents the continuous discharge of CW at peak rates from the facility.

The PW discharge characteristics for Cases P and M are summarised in Table 2.2. Case P represents the continuous discharge of PW at peak rates from the facility. Case M represents an intermittent discharge of MEG as part of the PW stream during start-up and early operations. Note that the maximum MEG specification assumed for the purposes of modelling has since been updated, which is reflected in the Environmental Impact Statement (EIS)/Environmental Review Document (ERD).

The hydrotest discharge characteristics for Cases H1, H2, H3a and H3b are summarised in Table 2.3. These cases represent potential one-off discharges of hydrotest fluid from PLETs at the NRC tie-in, Torosa and Brecknock/Calliance locations following installation and commissioning of the BTL and inter-field spur line.

Indicative concentrations of the constituents of interest within the CW (chlorine), PW (total oil, mercury and MEG) and hydrotest (biocide) discharges are described in Table 2.4, Table 2.5 and Table 2.6, respectively. The indicated concentrations were based on the engineering definitions available at the time of commissioning the dispersion modelling study and should not be considered definitive.

2.1.3.2 Ambient Environmental Conditions

Inputs of ambient environmental conditions to the UM3 model included a vertical profile of temperature and salinity, along with constant current speeds and general direction. The temperature and salinity profiles are required to accurately account for the buoyancy of the diluting plume, while the current speeds control the intensity of initial mixing and the deflection of the CW, PW and hydrotest plumes. These inputs are described in the following sections.

2.1.3.2.1 Ambient Temperature and Salinity

Temperature and salinity data applied to the near-field modelling was sourced from the World Ocean Atlas 2013 (WOA13) database produced by the National Oceanographic Data Centre (National Oceanic and Atmospheric Administration, NOAA) and its co-located World Data Center for Oceanography (Levitus *et al.*, 2013).

Table 2.7, Table 2.8 and Table 2.9 show the average seasonal water temperature and salinity levels at varying depths from 0 m to 500 m (depending on the location). This data can be considered representative of seasonal conditions at the Torosa FPSO/PLET, Brecknock/Calliance PLET and NRC tie-in PLET locations, respectively.

The seasonal temperature profiles exhibit a reasonably consistent reduction in temperature with increasing depth. Salinity levels are generally more consistent and exhibit a vertically well-mixed water body (34.3-34.6 practical salinity unit, PSU), irrespective of season or depth.

Table 2.7 Average temperature and salinity levels adjacent to the proposed Torosa FPSO/PLET locations.

Season	Depth (m)	Temperature (°C)	Salinity (PSU)

2.1.3.2.2 Ambient Current

Ocean current data was sourced from a ten-year hindcast data set of combined large-scale ocean (BRAN) and tidal currents. The data was statistically analysed to determine the 5th, 50th and 95th percentile current speeds. These statistical current speeds can be considered representative of seasonal conditions at the Torosa FPSO/PLET, Brecknock/Calliance PLET and NRC tie-in PLET locations.

Table 2.10, Table 2.11 and Table 2.12 present the steady-state, unidirectional current speeds at varying depths used as input to the near-field model as forcing for each discharge case at the Torosa FPSO/PLET, Brecknock/Calliance PLET and NRC tie-in PLET locations, respectively:

- 5th percentile current speed: weak currents, low dilution and slow advection.
- 50th percentile (median) current speed: average currents, moderate dilution and advection.
- 95th percentile current speed: strong currents, high dilution and rapid advection to nearby areas.

The 5th, 50th and 95th percentile values are referenced as weak, medium and strong current speeds, respectively.

Table 2.10 Adopted ambient current conditions adjacent to the proposed Torosa FPSO/PLET locations.

Season	Depth (m)	5th Percentile (Weak) Current Speed (m/s)	50th Percentile (Medium) Current Speed (m/s)	95th Percentile (Strong) Current Speed (m/s)

2.2 Far-Field Modelling

2.2.1 Overview

The far-field modelling expands on the near-field work by allowing the time-varying nature of currents to be included, and the potential for recirculation of the plume back to the discharge location to be assessed. In this case, concentrations near the discharge point can be increased due to the discharge plume mixing with the remnant plume from an earlier time. This may be a potential source of episodic increases in plume concentrations in the receiving waters.

2.2.2 Description of Far-Field Model: CHEMMAP

The mixing and dispersion of the CW discharges was predicted using the three-dimensional discharge and plume behaviour model, CHEMMAP (French-McCay & Isaji, 2004; French-McCay *et al.*, 2006).

CHEMMAP predicts the movement and fate of a wide variety of chemical products, including floating, sinking, soluble/insoluble chemicals and product mixtures (French-McCay & Isaji, 2004). CHEMMAP incorporates many important chemical modelling components, including: transport and spreading of floating chemicals; transport of dissolved or particulate chemicals in three dimensions; evaporation or volatilisation of chemicals at the surface; dissolution; re-suspension; sedimentation; and degradation of chemicals in air, water and sediments (French-McCay *et al.*, 2006).

The most important inputs associated with the chemical model are the physical properties relating to the released chemical. The properties used to predict the fate and transport of each chemical include density, vapour pressure, water solubility, environmental degradation rates, adsorbed/dissolved partitioning coefficients (K_{OW}, K_{OC}), viscosity and surface tension (French-McCay *et al.*, 2006). CHEMMAP contains its own chemical database and the information found within this database is compiled from published literature sources (French-McCay & Payne, 2008).

The transport algorithm within CHEMMAP depends heavily on the precision of the input current data (French-McCay & Whittier, 2004). The model uses a Lagrangian three-dimensional transport model to predict the movement of the chemical in the water column, on the surface and in the air (French-McCay & Whittier, 2004).

For each time step, the model calculates the phase transfer percentages and changes the state of particular proportions of the spilled chemical (French-McCay & Isaji, 2004). This may mean that a chemical changes from a substance floating on the surface to a gas, or is dissolved into the water column. The evaporation algorithm used in the CHEMMAP model has been tested by comparison to experimental data from Kawamura & Mackay (1987) and French-McCay & Whittier (2004).

2.2.3 Description of Far-Field Model: MUDMAP

The mixing and dispersion of the PW and hydrotest discharges was predicted using the three-dimensional discharge and plume behaviour model, MUDMAP (Koh & Chang, 1973; Khondaker, 2000).

The far-field calculation (passive dispersion stage) employs a particle-based, random walk procedure. Any chemicals/constituents within the discharge stream are represented by a sample of Lagrangian particles. These particles are moved in three dimensions over each subsequent time step according to the prevailing local current data as well as horizontal and vertical mixing coefficients.

MUDMAP treats the Lagrangian particles as conservative tracers (i.e. they are not removed over time to account for chemical interactions, decay or precipitation). Predicted concentrations will therefore be conservative overestimates where these processes actually do occur. Each particle represents a proportion of the discharge, by mass, and particles are released at a given rate to represent the rate of the discharge (mass per unit time). Concentrations of constituents are predicted over time by counting the number of particles that occur within a given depth level and grid square and converting this value to mass per unit volume.

The system has been extensively validated and applied for discharge operations in Australian waters (e.g. Burns *et al.*, 1999; King & McAllister, 1997, 1998).

2.2.4 Stochastic Modelling

A stochastic modelling procedure was applied in the far-field modelling to sample a representative set of conditions that could affect the distribution of constituents. This approach involves multiple possible simulations of a given discharge scenario and season (50 for the CW and PW discharges; 25 for the hydrotest discharges), with each simulation being carried out under a randomly-selected period of currents. This methodology ensures that the calculated movement and fate of each discharge is representative of the range of prevailing currents at the discharge location. Once the stochastic modelling is complete, all simulations are statistically analysed to develop the distribution of outcomes based on time and event.

The stochastic simulations are jointly processed as an aggregated set for each season. This is done by building a time series of maximum constituent concentrations, at any depth in the water column within each model grid cell, for all time steps of all replicate simulations. The resultant time series at each grid cell is a representation of the stochastic outcomes, and this is statistically analysed to allow percentile data (representing the percentage of time that particular concentrations occur) to be generated. The resultant percentile concentration contours, and the initial source concentration of the discharge, are used to determine the dilution contours for each percentile.

To calculate the tabulated results of dilutions at particular distances from the source location, all grid cells at the specified radial distances (e.g. 100 m), including a buffer zone of 10 m either side (e.g. every grid cell in the 90-110 m range), are interrogated. The minimum dilution is calculated as the lowest value in any individual non-zero grid cell within the defined range, including the buffer zone. The average dilution is calculated as the average value across all non-zero grid cells within the defined range, including the buffer zone. This is done for all defined radial distances from the source location for each percentile.

The process is similar on the outer edge of the Scott Reef receptor, where there is a 10 m buffer zone, but on the inside the entire receptor area is considered in order to capture details of the plume characteristics at all points predicted to be affected. The analysis is therefore not restricted only to the receptor boundary line. The minimum dilution is calculated as the lowest value in any individual non-zero grid cell within the receptor area (plus the 10 m outer buffer), while the average dilution is calculated as the average value across all non-zero grid cells within the receptor area (plus the 10 m outer buffer). In practice, because the aggregated plume concentrations generally decrease as the plume penetrates further into the receptor (with dilution levels therefore increasing), the minimum dilutions identified by the analysis are usually found on or very close to the boundary line.

2.2.5 Setup of Far-Field Model

2.2.5.1 Discharge Characteristics

The CHEMMAP and MUDMAP models simulated the discharge into a time-varying current field with the initial dilution set by the near-field results described in Section 2.1.

The CW and PW discharge scenarios were modelled as a continuous discharge using 50 simulations for each season, while the hydrotest discharge scenarios were modelled as a one-off discharge using 25 simulations for each season. A reduced number of hydrotest simulations was justified in light of the significantly longer duration of most of these scenarios (>20 days in three of four cases) relative to the duration of all CW and PW scenarios (5 days). Even with fewer replicates, the range of environmental conditions sampled from the ten-year hindcast data set during the hydrotest simulations was similarly extensive to (or more extensive than) that sampled during the CW and PW simulations.

Once the simulations were complete, they were reported on a seasonal basis: (i) summer (December to February); (ii) transitional (March and September to November) and (iii) winter (April to August). The CW, PW and hydrotest discharge characteristics for all cases are summarised in Table 2.13, Table 2.14 and Table 2.15, respectively.

Table 2.13 Summary of far-field CW discharge modelling assumptions.

Parameter	Case C
Hindcast modelling period	2006-2015
Seasons	Summer (December to February) Transitional (March and September to November) Winter (April to August) Annual
Flow rate (m^3/d)	720,000
Discharge depth (m)	12
Discharge salinity (ppt)	35
Discharge temperature (°C)	50
Number of simulations	150 (50 per season)
Simulated discharge type	Continuous
Simulated discharge period (days)	5

Table 2.14 Summary of far-field PW discharge modelling assumptions.

Parameter	Case P	Case M
Hindcast modelling period	2006-2015	
Seasons	Summer (December to February) Transitional (March and September to November) Winter (April to August) Annual	
Flow rate (m^3/d)	5,723	490
Discharge depth (m)	14	
Discharge salinity (ppt)	9.5	0.0
Discharge temperature (°C)	50

Number of simulations	75 (25 per season)			
Simulated discharge type	One-off			
Simulated discharge period (days)	21	24	22	4

2.2.5.2 Mixing Parameters

The horizontal and vertical dispersion coefficients represent the mixing and diffusion caused by turbulence, both of which are sub-grid-scale processes. Both coefficients are expressed in units of rate of area change per second (m^2/s). Increasing the horizontal dispersion coefficient will increase the horizontal spread of the discharge plume and decrease the centreline concentrations faster. Increasing the vertical dispersion coefficient spreads the discharge across the vertical layers (or depths) faster.

Spatially constant, conservative dispersion coefficients of 0.25 m^2/s and 0.00001 m^2/s were used to control the spreading of the CW, PW and hydrotest plumes in the horizontal and vertical directions, respectively. Each of the mixing parameters was selected following extensive sensitivity testing to recreate the plume characteristics predicted by the near-field modelling. It would be expected that the in situ mixing dynamics would be greater under average and high energy conditions by a factor of 10 (King & McAllister, 1997, 1998) and thus the far-field model results are designed to produce a worst-case result for concentration extents.

2.2.5.3 Grid Configuration

CHEMMAP and MUDMAP each use a three-dimensional grid to represent the geographic region under study (water depth and bathymetric profiles). Due to the rapid mixing and small-scale effect of the effluent discharge, it was necessary to use a fine grid with a resolution of 40 m x 40 m (CW and hydrotest discharges) and 20 m x 20 m (PW discharges) to track the movement and fate of the discharge plume. The extent of the grid region measured approximately 40 km (longitude or x-axis) by 40 km (latitude or y-axis) for CW and hydrotest discharges, and approximately 20 km by 20 km for PW discharges, each of which was subdivided horizontally into 1,000 x 1,000 cells. The vertical resolution was set to 1 m (CW and PW discharges) and 2 m (hydrotest discharges).

2.2.1 Regional Ocean Currents

2.2.1.1 Background

The area of interest for this study is located within the influence of the Indonesian Throughflow, a large-scale current system characterised as a series of migrating gyres and connecting jets that are steered by the continental shelf. While the mass flow is generally towards the south-west, year-round, the internal gyres generate local currents in all directions. As these gyres migrate through the area, large spatial variations in the speed and direction of currents will occur at a given location over time. Further south of the project area, the Leeuwin Current becomes the dominant large-scale current system, flowing poleward down the pressure gradient along the Western Australian coastline and past Cape Leeuwin.

Offshore regions with water depths exceeding 100-200 m experience significant large-scale drift currents. These drift currents can be relatively strong (1-2 knots) and complex, manifesting as a series of eddies, meandering currents and connecting flows. These offshore drift currents also tend to persist longer (days to weeks) than tidal current flows (hours between reversals) and thus will have greater influence upon the net trajectory of plumes over time scales exceeding a few hours.

On the continental shelf, in shallower waters around Scott Reef and closer to the inshore region of the Kimberley Coast, surface winds and tidal dynamics dominate over the large scale current flows (Condie & Andrewartha, 2008). In comparison to drift currents, tidal currents generate only relatively short tidal migrations (distance travelled by a parcel of water over a tidal cycle) that follow an elliptical path with a period of about 12 hours in the study region. Hence, tidal currents add variability to the longer-term drift patterns of an entrained plume.

Wind shear on the water surface also generates local-scale currents that can persist for extended periods (hours to days) and result in long trajectories. Persistent winds along the mainland coast can induce Ekman transport, where surface waters move offshore and facilitate upwelling events in which cold nutrient-rich waters from the deep Indian Ocean are brought to the surface. However, due to the opposing transport of warm tropical waters by the Leeuwin Current, large-scale persistent upwelling along the Western Australian coast is suppressed. Therefore, upwelling events are sporadic, short-term and localised to areas of the coastline where the continental shelf narrows, including the area around the Capes and the Ningaloo coast (IMOS, 2015). This process is seasonal/transient and affected by the strength of the Leeuwin Current, with minimal upwelling in times with strong Leeuwin Current flow.

The current-induced transport of plumes can be variably affected by combinations of tidal, wind-induced and density-induced drift currents. Depending on their local influence, it is critical to consider all these potential advective mechanisms to rigorously understand patterns of potential transport from a given discharge location.

To appropriately allow for temporal and spatial variation in the current field, dispersion modelling requires the current speed and direction over a spatial grid covering the potential migration trajectories of plumes. As long-term measured current data is not available for simultaneous periods over a network of locations covering the offshore areas relevant to this study, the analysis relied upon hindcasts of the circulation generated through numerical modelling by internationally recognised organisations.

A composite modelled ocean current data product was derived by combining predictions of mesoscale circulation currents, available at daily resolution from global ocean models, with predictions of the hourly tidal currents generated by the RPS HYDROMAP model. By combining a drift current model with a tidal model, the influences of inter-annual and seasonal drift patterns, and the more regular variations in tide, were depicted, ensuring nearshore and offshore hydrodynamic processes were represented.

2.2.1.2 Mesoscale Circulation

2.2.1.2.1 Description of Mesoscale Model: BRAN

Two mesoscale ocean current data sets were considered for the study: the CSIRO (Commonwealth Scientific and Industrial Research Organisation) global ocean model, BRAN (Bluelink ReANalysis); and the HYCOM (Hybrid Coordinate Ocean Model) Consortium's global ocean model, HYCOM. Based on a hydrodynamic model validation conducted by RPS, the output of the BRAN (Oke *et al.*, 2008, 2009; Schiller *et al.*, 2008) ocean model, which is sponsored by the Australian Government through the Commonwealth Bureau of Meteorology (BoM), Royal Australian Navy and CSIRO, was chosen for representation of the drift currents that affect the area. BRAN is a data-assimilative, three-dimensional ocean model that has been run as a hindcast for many periods and is now used for ocean forecasting (Schiller *et al.*, 2008).

BRAN routinely assimilates sea level anomaly data, tide gauge data, sea surface temperature and in situ temperature and salinity measurements (Oke *et al.*, 2009). Comparisons of BRAN hindcast outputs to satellite and independent in situ observations found that BRAN was reliably representing the broad-scale ocean circulation, the mesoscale surface eddy field, and shelf circulation around Australia (Oke *et al.*, 2008; Schiller *et al.*, 2008). Additionally, reanalysis of past periods using the BRAN model has been shown to realistically represent upwelling events, in particular along the Bonney Coast of South Australia, a region of frequent wind-driven upwellings (Oke *et al.*, 2009).

The BRAN predictions for drift currents are produced at a horizontal spatial resolution of approximately 0.1° over the region, at a frequency of once per day, averaged over the 24-hour period. Hence, the BRAN model data provides estimates of mesoscale circulation with horizontal resolution suitable to resolve eddies of a few tens of kilometres' diameter, as well as connecting stream currents of similar spatial scale. Drift currents that are represented over the inner shelf waters in the BRAN data are principally attributable to wind induced drift.

There are several versions of the BRAN database available. The latest BRAN simulation spans the period of January 1994 to August 2016. From this database, three-dimensional data representing horizontal water movement at discrete depths was extracted for all points in the model domain for the years 2006-2015 (inclusive). The data was assumed to be a suitably representative sample of the current conditions over the study area for future years.

Although this data should represent effects of upwelling and downwelling processes on horizontal transport at a given depth, the data does not explicitly represent vertical currents between horizontal layers. This was considered reasonable because vertical currents associated with episodic upwelling and downwelling events are relatively small in magnitude (3-30 cm/s; Kampf *et al.*, 2004) compared to horizontal currents represented in the tidal and non-tidal current data (0.5-2 m/s), and considering allowances for dispersion rates in the horizontal (0.1-50 m/s) and vertical (1-10 cm/s) planes.

2.2.1.2.2 Mesoscale Current Validation

The suitability of the BRAN ocean model product was evaluated by comparing the predicted currents to those measured within the Browse project area. The validation included both quantitative and qualitative comparisons between measured and modelled data at a range of depths through the water column, at three available measurement locations shown in Figure 2.3: Browse C1-1 (three depth layers), B2-1 (eight depth layers) and G2-1 (three depth layers).

Time series comparisons of modelled and measured current magnitude, direction, and U/V velocity components are presented for sites B2-1 (Figure 2.4 and Figure 2.5), C1-1 (Figure 2.6 and Figure 2.7) and G2-1 (Figure 2.8 and Figure 2.9). For the purposes of brevity and clarity, only a surface and mid-depth time series at each site was selected for presentation. The time series comparisons revealed that, at two of the sites (B2-1 and G2-1), the BRAN model offered a good match in magnitude and direction of the measured current velocity in the upper water column; however, the magnitudes of the peaks and troughs were often underpredicted at the deeper levels. At the C1-1 site, the BRAN model captured the range in current magnitude at each depth; however, the timing of peaks and troughs in the measured current velocity and direction was not well-matched. Given the location of this site in close proximity to Scott Reef, with steep gradients in the bathymetry and the relatively coarse resolution of the ocean model (relative to the tidal model), this was not unexpected.

A quantitative analysis of the BRAN model's skill at replicating the drift currents was conducted using the Index of Agreement (IOA), presented in Willmott (1981) and Willmott *et al.* (1985), and the Mean Absolute Error (MAE), discussed in Willmott (1982) and Willmott & Matsuura (2005). A perfect agreement can be said to exist between the model and field observations if the IOA gives a measure of one, and complete disagreement will produce an IOA measure of zero (Willmott, 1981). The MAE is simply the average of the absolute values of the differences between the observed and modelled values.

The IOA and MAE values derived from comparisons of the U/V velocity components over the full measurement period at sites B2-1, C1-1 and G2-1 for all available water depths are presented in Table 2.16. The results confirm the conclusions drawn from analysis of the comparison time series plots. The IOA for both velocity components is good at sites B2-1 and G2-1 in the upper water column but reduces at deeper layers. This reflects the generally good match in the range, magnitude and direction of the measured and modelled drift currents at these sites, particularly in the upper water column. The IOA for both velocity components at site C1-1 is low, suggesting a poor agreement, reflecting the poor match in the timing of peaks and troughs in velocity observed in the time series plots.

Overall, the BRAN model data offered a reasonable match to the field measurements within the Browse project area, particularly in the upper water column. Given the stochastic methodology applied in far-field modelling, the use of a ten-year hindcast of BRAN current data allowed a realistic spatial distribution of potential plume trajectories and extents to be captured in aggregate. The BRAN model was considered suitable for use in the marine dispersion modelling studies.

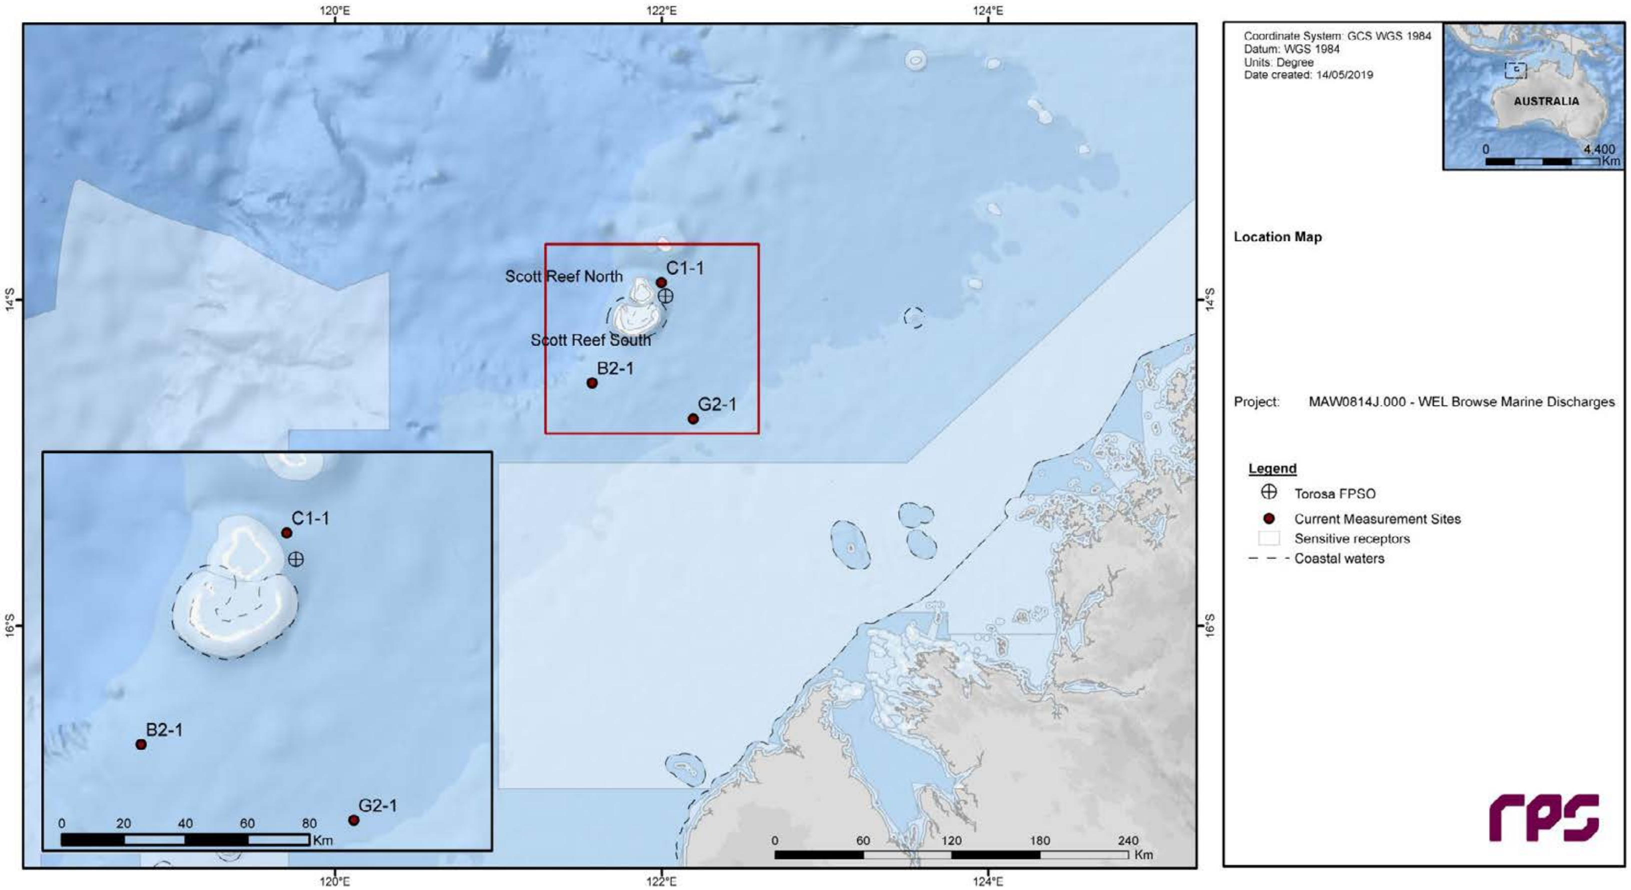

Figure 2.3 Locations of the proposed Torosa FPSO and the current measurement sites used for model validation, in proximity to Scott Reef, off the Kimberley Coast of Western Australia.

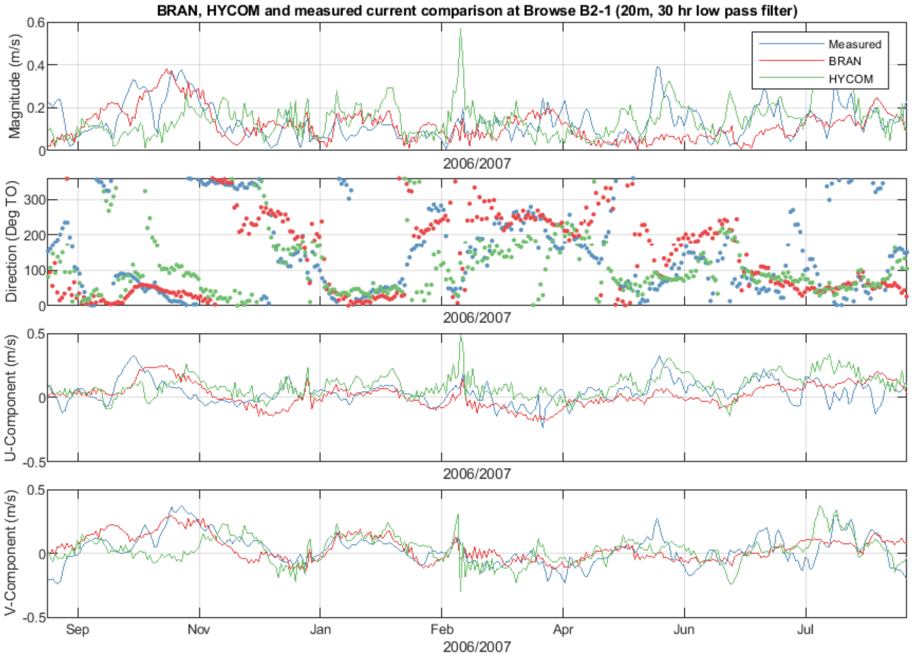

Figure 2.4 Comparisons between BRAN-predicted (red line), HYCOM-predicted (green line) and measured (blue line) non-tidal current data at site B2-1, at a depth of approximately 20 m, for the period of August 2006 to July 2007.

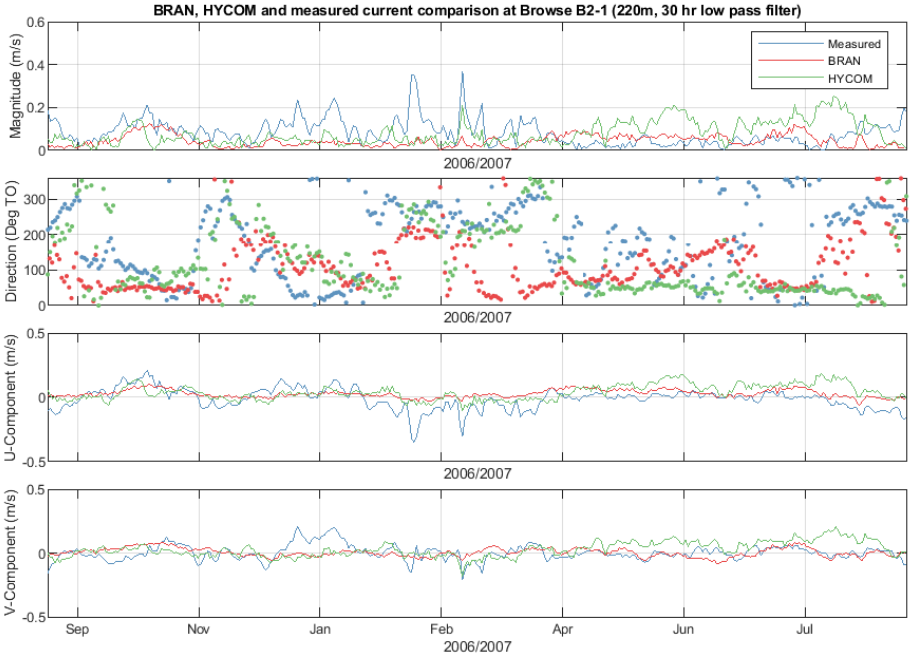

Figure 2.5 Comparisons between BRAN-predicted (red line), HYCOM-predicted (green line) and measured (blue line) non-tidal current data at site B2-1, at a depth of approximately 220 m, for the period of August 2006 to July 2007.

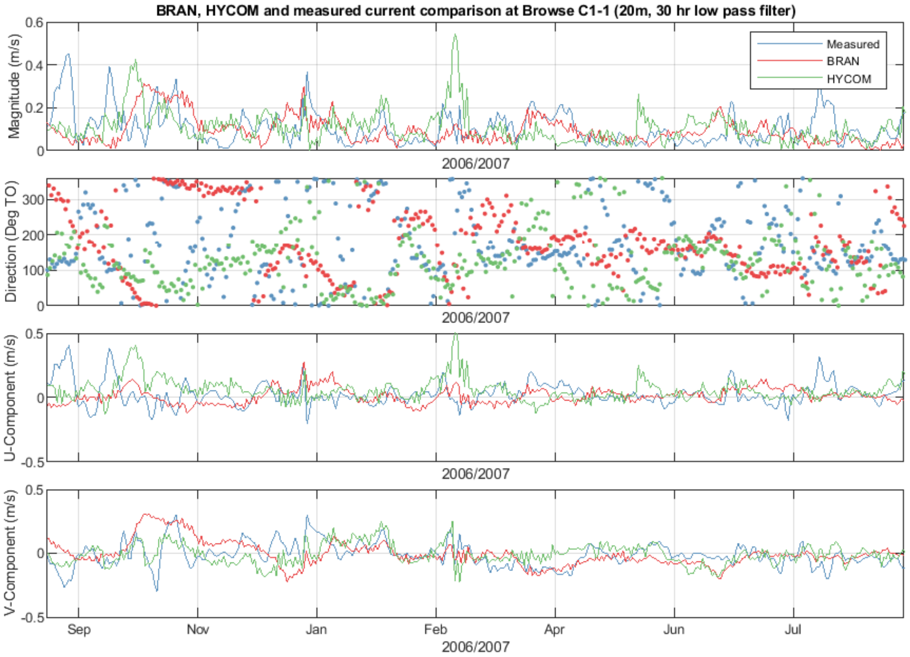

Figure 2.6 Comparisons between BRAN-predicted (red line), HYCOM-predicted (green line) and measured (blue line) non-tidal current data at site C1-1, at a depth of approximately 20 m, for the period of August 2006 to July 2007.

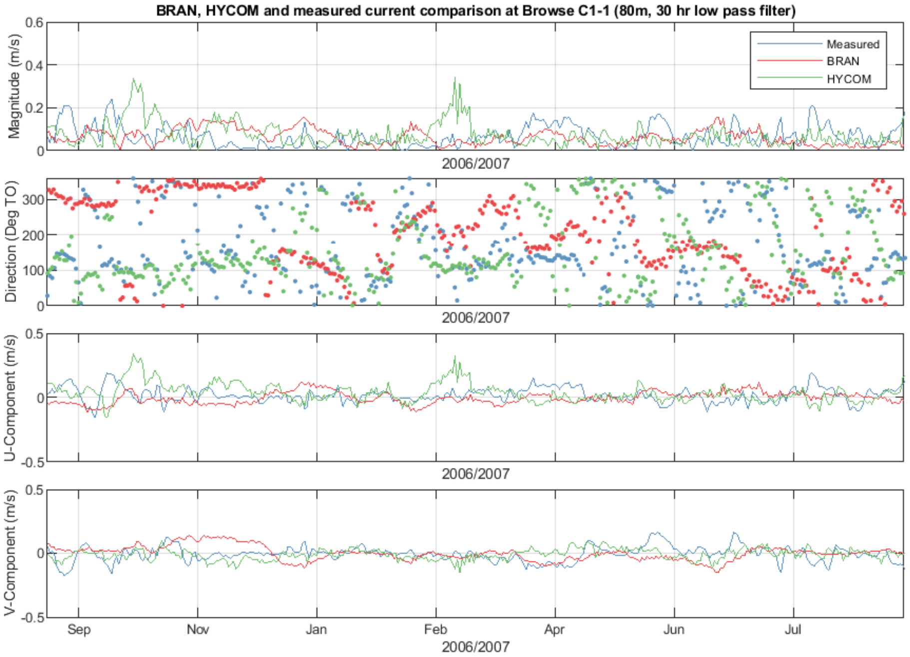

Figure 2.7 Comparisons between BRAN-predicted (red line), HYCOM-predicted (green line) and measured (blue line) non-tidal current data at site C1-1, at a depth of approximately 80 m, for the period of August 2006 to July 2007.

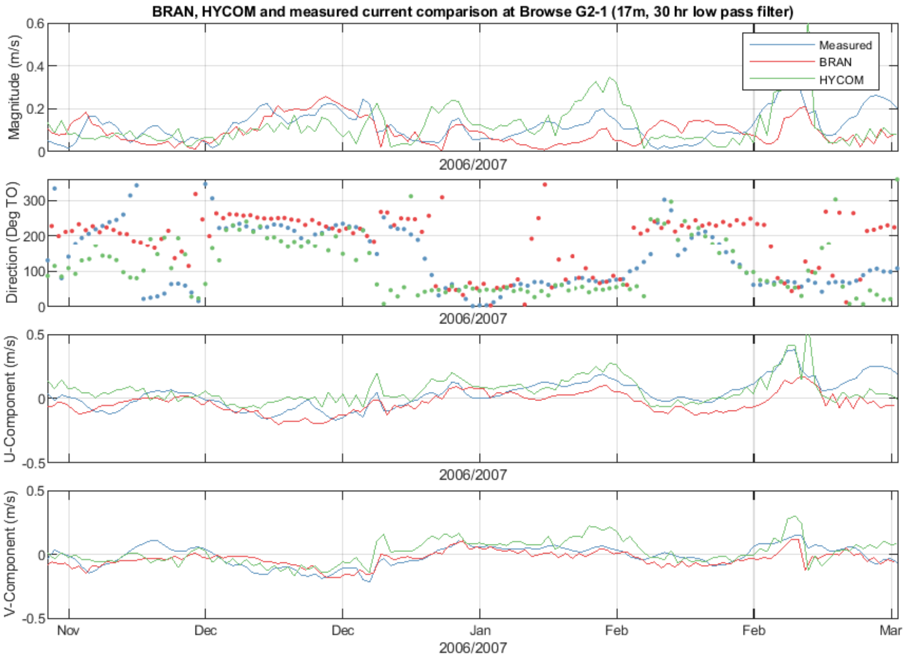

Figure 2.8 Comparisons between BRAN-predicted (red line), HYCOM-predicted (green line) and measured (blue line) non-tidal current data at site G2-1, at a depth of approximately 17 m, for the period of August 2006 to July 2007.

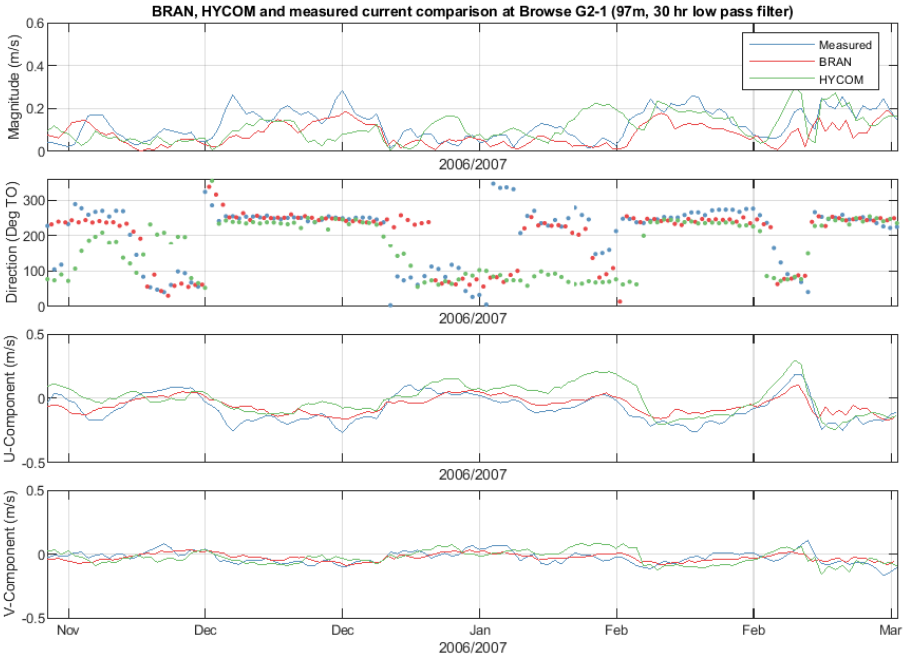

Figure 2.9 Comparisons between BRAN-predicted (red line), HYCOM-predicted (green line) and measured (blue line) non-tidal current data at site G2-1, at a depth of approximately 97 m, for the period of August 2006 to July 2007.

2.2.1.2.3 Mesoscale Currents at the Discharge Locations

Figure 2.10, Figure 2.11 and Figure 2.12 show the seasonal distribution of current speeds and directions for the BRAN data points closest to the Torosa FPSO/PLET, Brecknock/Calliance PLET and NRC tie-in PLET locations, respectively. Note that the convention for defining current direction is the direction towards which the current flows.

The data near the Torosa locations (Figure 2.10) shows that current speeds and directions vary between seasons. In general, during summer (December to February) currents have the strongest average speed (0.13 m/s with a maximum of 0.42 m/s). Lower current speeds are typical of the transitional (March and September to November; 0.11 m/s with a maximum of 0.36 m/s) and winter (April to August; 0.10 m/s with a maximum of 0.28 m/s) seasons. Flow is expected to occur with a reasonably equitable distribution in all directions, but northerly and westerly flows are slightly more prevalent across the year.

The data near the Brecknock/Calliance location (Figure 2.11) shows that current speeds and directions are relatively consistent between seasons. In general, during summer currents have the strongest average speed (0.13 m/s with a maximum of 0.41 m/s). North-easterly flows are expected to be dominant across all seasons.

The data near the NRC tie-in location (Figure 2.12) shows that current speeds and directions are relatively consistent between seasons. In general, during the transitional season currents have the strongest average speed (0.10 m/s), with maximum current speeds of 0.40 m/s occurring during summer. South-westerly flows are expected to be dominant across all seasons.

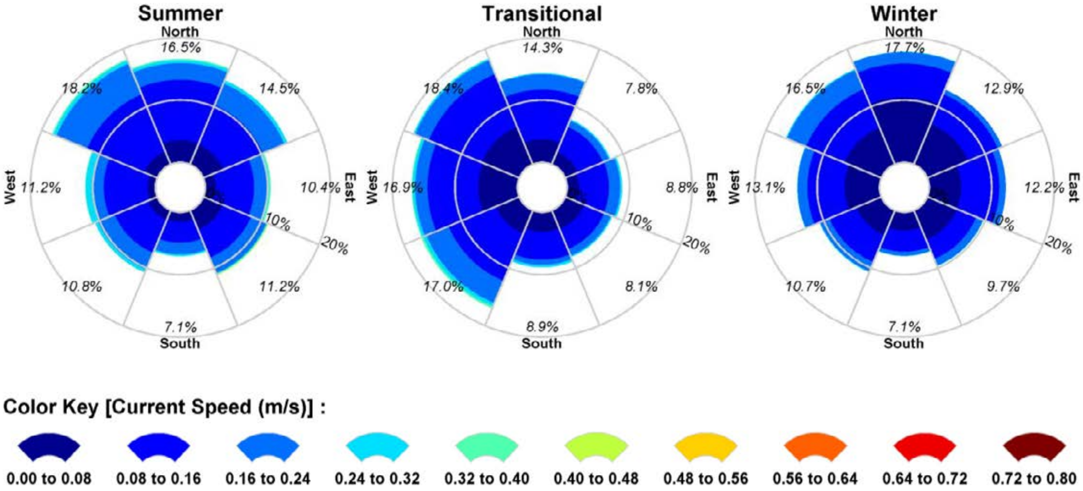

Figure 2.10 Seasonal current distribution (2006-2015, inclusive) derived from the BRAN database near to the proposed Torosa FPSO/PLET locations. The colour key shows the current magnitude, the compass direction provides the direction towards which the current is flowing, and the size of the wedge gives the percentage of the record.

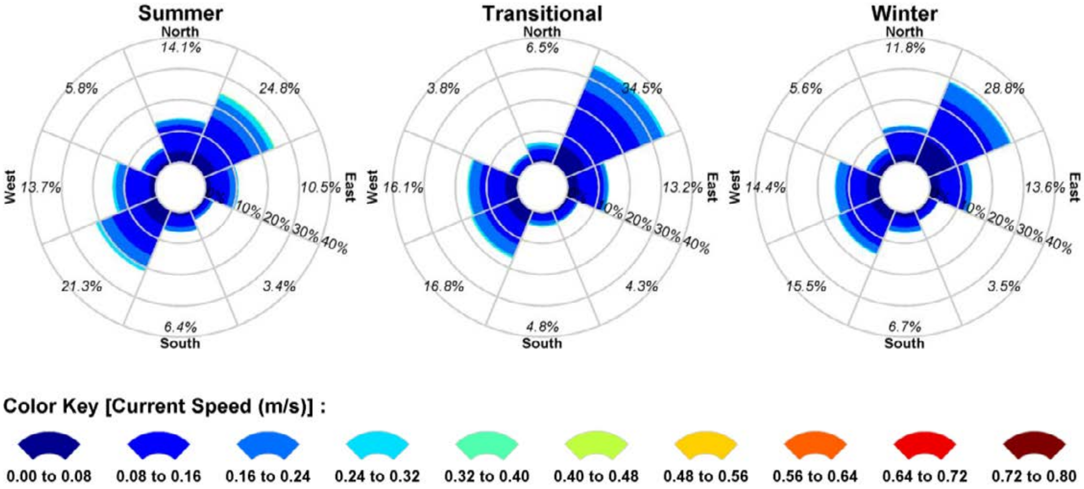

Figure 2.11 Seasonal current distribution (2006-2015, inclusive) derived from the BRAN database near to the proposed Brecknock/Calliance PLET location. The colour key shows the current magnitude, the compass direction provides the direction towards which the current is flowing, and the size of the wedge gives the percentage of the record.

2.2.1.3 Tidal Circulation

2.2.1.3.1 Description of Tidal Model: HYDROMAP

As the BRAN model does not include tidal forcing, and because the data is only available at a daily frequency, a tidal model was developed for the study region using RPS' three-dimensional hydrodynamic model, HYDROMAP.

The model formulations and output (current speed, direction and sea level) of this model have been validated through field measurements around the world for more than 30 years (Isaji & Spaulding, 1984, 1986; Isaji *et al.*, 2001; Zigic *et al.*, 2003). HYDROMAP current data has also been widely used as input to forecasts and hindcasts of oil spill migrations in Australian waters. This modelling system forms part of the National Marine Oil Spill Contingency Plan for the Australian Maritime Safety Authority (AMSA, 2002).

HYDROMAP simulates the flow of ocean currents within a model region due to forcing by astronomical tides, wind stress and bottom friction. The model employs a sophisticated dynamically nested-gridding strategy, supporting up to six levels of spatial resolution within a single domain. This allows for higher resolution of currents within areas of greater bathymetric and coastline complexity, or of particular interest to a study.

The numerical solution methodology of HYDROMAP follows that of Davies (1977a, 1977b) with further developments for model efficiency by Owen (1980) and Gordon (1982). A more detailed presentation of the model can be found in Isaji & Spaulding (1984).

2.2.1.3.2 Tidal Domain Setup

A HYDROMAP model was established over a domain that extended approximately 3,300 km east-west by 3,100 km north-south over the eastern Indian Ocean. The grid extends beyond Eucla in the south and beyond Bathurst Island in the north (Figure 2.13). Approximately 98,600 cells were used to define the region, with four layers of sub-gridding applied to provide variable resolution throughout the domain. The resolution at the primary level was 15 km. The finer levels were defined by subdividing these cells into 4, 16 and 64 cells, resulting in resolutions of 7.5 km, 3.75 km and 1.88 km.

The finer grids were allocated in a step-wise fashion to areas where higher resolution of circulation patterns was required to resolve flows through channels, around shorelines or over more complex bathymetry. Figure 2.14 shows a zoomed subset of the hydrodynamic model grid in the Scott Reef region, showing the finer resolution grids surrounding Scott Reef, the numerous shoals and islands, and complex areas of the mainland coastline.

Modelling of the tidal circulation at relatively fine scales in the topographically-complex area around Scott Reef was achieved using an additional model sub-domain with resolutions ranging down to <500 m. Major tidal channels that occur across the reef flats of North Scott Reef were represented in this model, with tidal current flows across the rest of the flats known to be minimal.

High-resolution (~50 m) bathymetric data covering Scott and Seringapatam Reefs and the Brecknock, Torosa and Calliance gas fields was supplied by Woodside. Beyond these areas, bathymetric data used to define the three-dimensional shape of the study domain was extracted from the Geoscience Australia 250 m resolution bathymetry database (GA, 2009) and the CMAP electronic chart database, supplemented where necessary with manual digitisation of chart data supplied by the Australian Hydrographic Office. Depths in the domain ranged from shallow intertidal areas through to approximately 7,200 m.

2.2.1.3.3 Tidal Boundary Conditions

Ocean boundary data for the HYDROMAP model was obtained from the TOPEX/Poseidon global tidal database (TPXO7.2) of satellite-measured altimetry data, which provided estimates of tidal amplitudes and phases for the eight dominant tidal constituents (designated as K_2, S_2, M_2, N_2, K_1, P_1, O_1 and Q_1) at a horizontal scale of approximately 0.25°. Using the tidal data, sea surface heights are firstly calculated along the open boundaries at each time step in the model.

The TOPEX/Poseidon satellite data is produced, and quality controlled by the US National Atmospheric and Space Agency (NASA). The satellites, equipped with two highly accurate altimeters capable of taking sea level measurements accurate to less than ±5 cm, measured oceanic surface elevations (and the resultant tides) for over 13 years (1992-2005). In total, these satellites carried out more than 62,000 orbits of the planet. The TOPEX/Poseidon tidal data has been widely used amongst the oceanographic community, being the subject of more than 2,100 research publications (e.g. Andersen, 1995; Ludicone *et al.*, 1998; Matsumoto *et al.*, 2000; Kostianoy *et al.*, 2003; Yaremchuk & Tangdong, 2004; Qiu & Chen, 2010). As such, the TOPEX/Poseidon tidal data is considered suitably accurate for this study.

2.2.1.3.4 Tidal Elevation Validation

For the purpose of verification of the tidal predictions, the model output was compared against independent predictions of tides using the XTide database (Flater, 1998). The XTide database contains harmonic tidal constituents derived from measured water level data at locations around the world. Overall, there are more than 120 tidal stations within the HYDROMAP model domain; however, some of these are located in areas that are not sufficiently resolved by this large-scale ocean model. More than 80 stations along the coastline were suitable for comparisons of the model performance with the observed data. These stations covered the mid-to-northwest regions of the Western Australian coastline, encompassing the locales of the marine discharges considered in this study (Figure 2.13 and Figure 2.14). For the purposes of brevity and clarity, a selected representative subset of the available tidal station validation data is presented here.

Water level time series for the selected subset of ten stations are shown in Figure 2.15 and Figure 2.16 for a one-month period (January 2018). All comparisons show that the model produces a very good match to the known tidal behaviour for a wide range of tidal amplitudes and clearly represents the varying diurnal and semi-diurnal nature of the tidal signal.

The model skill was further evaluated through a comparison of the predicted and observed tidal constituents, derived from an analysis of model-predicted time series at each of the tidal station locations. Scatter plots of the observed and modelled amplitude (top) and phase (bottom) of the five dominant tidal constituents (S_2, M_2, N_2, K_1 and O_1) for all relevant stations within the model domain (>80) are presented in Figure 2.17. The red line on each plot shows the 1:1 line, which would indicate a perfect match between the modelled and observed data. Note that the data is generally closely aligned to the 1:1 line demonstrating the high quality of the model performance.

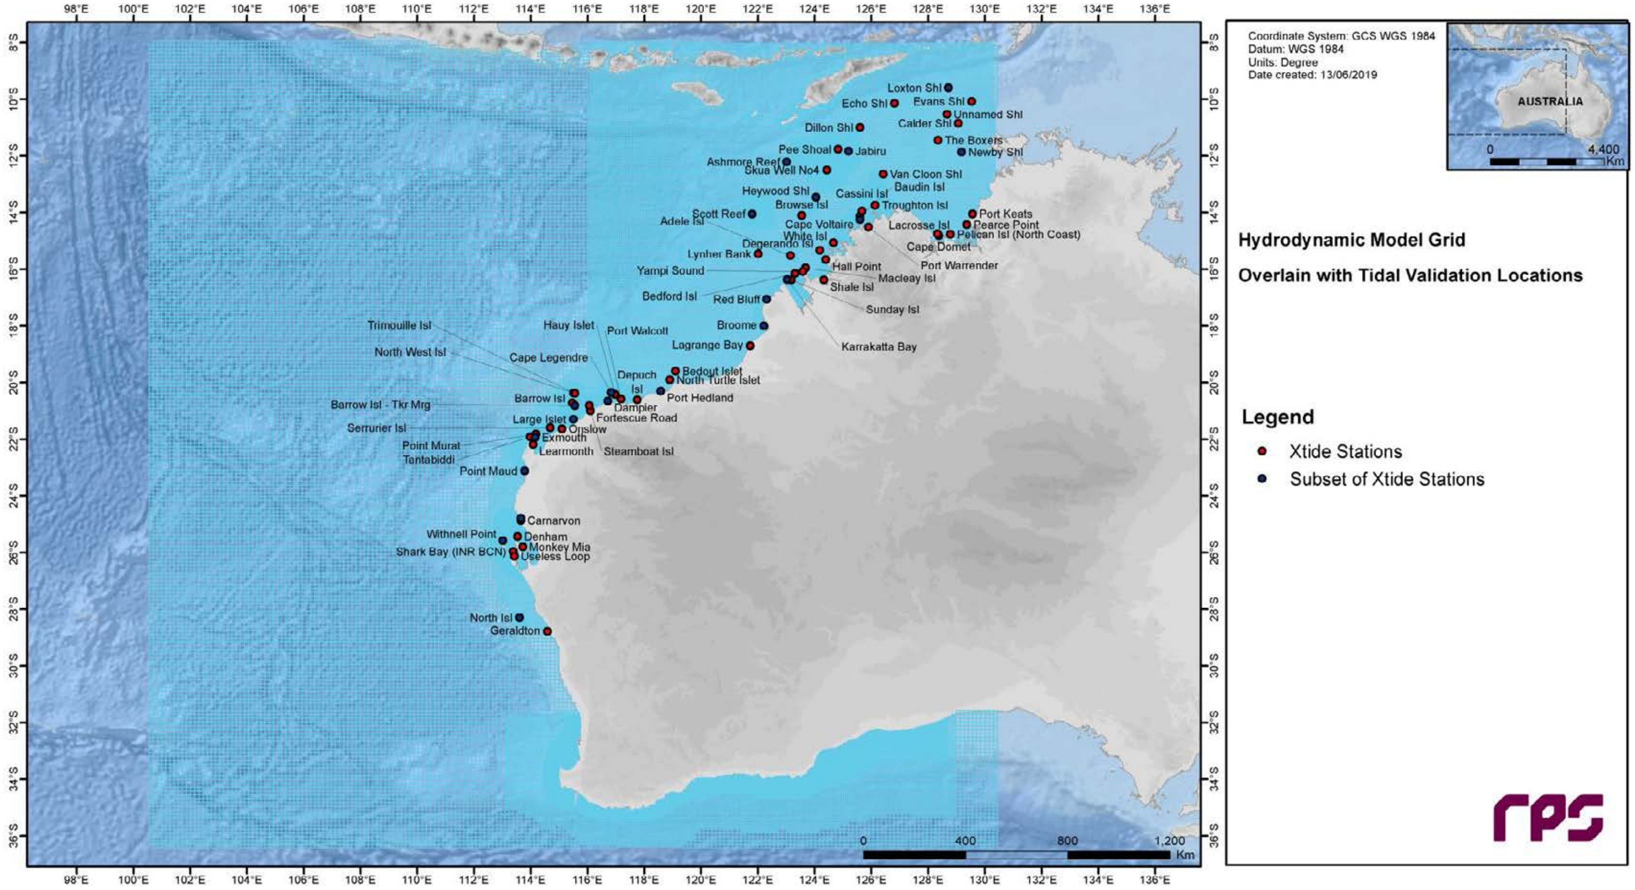

Figure 2.13 Hydrodynamic model grid (blue wire mesh) used to generate the tidal currents, showing the full domain in context with the continental land mass and the locations available for tidal comparisons (red and blue labelled dots). Higher-resolution areas are indicated by the denser mesh zones.

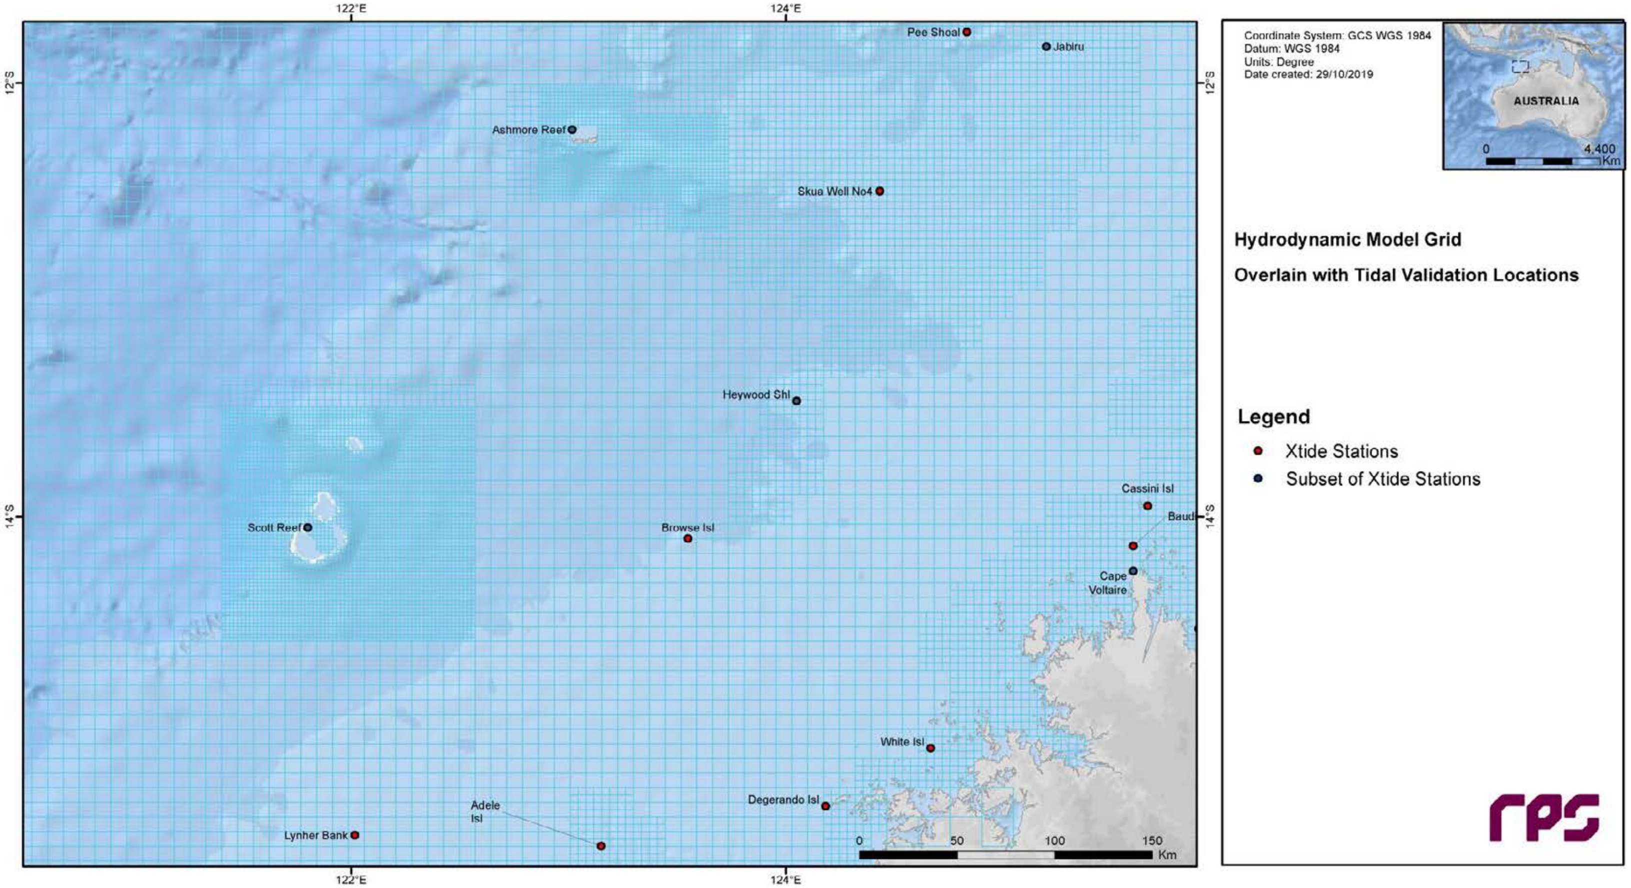

Figure 2.14 Zoomed subset of the hydrodynamic model grid (blue wire mesh) for the Scott Reef area, showing the locations available for tidal comparisons (red and blue labelled dots). Higher-resolution areas are indicated by the denser mesh zones.

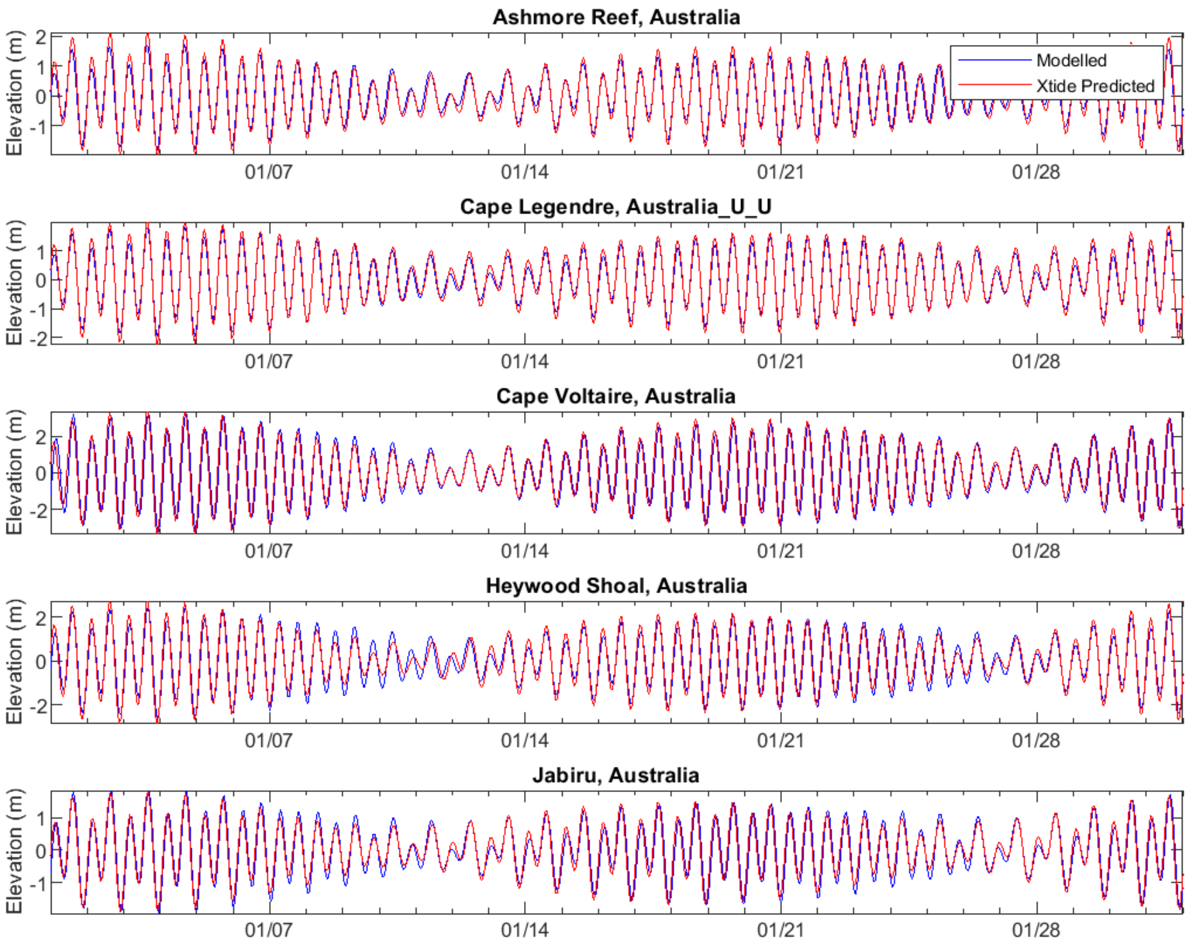

Figure 2.15 Comparisons between the predicted (blue line) and observed (red line) surface elevation variations at five locations in the north-east of the tidal model domain for January 2018.

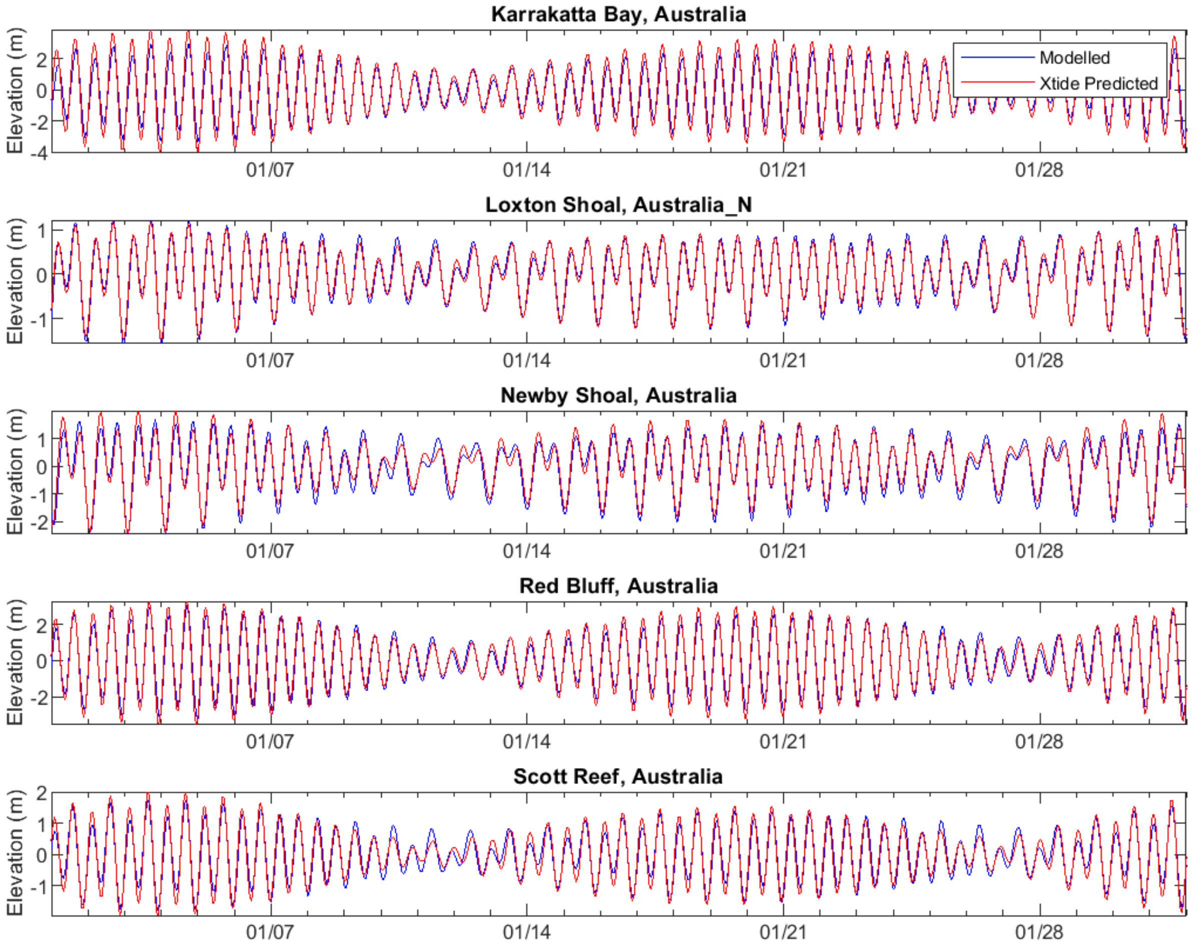

Figure 2.16 Comparisons between the predicted (blue line) and observed (red line) surface elevation variations at five locations in the north-east of the tidal model domain for January 2018.

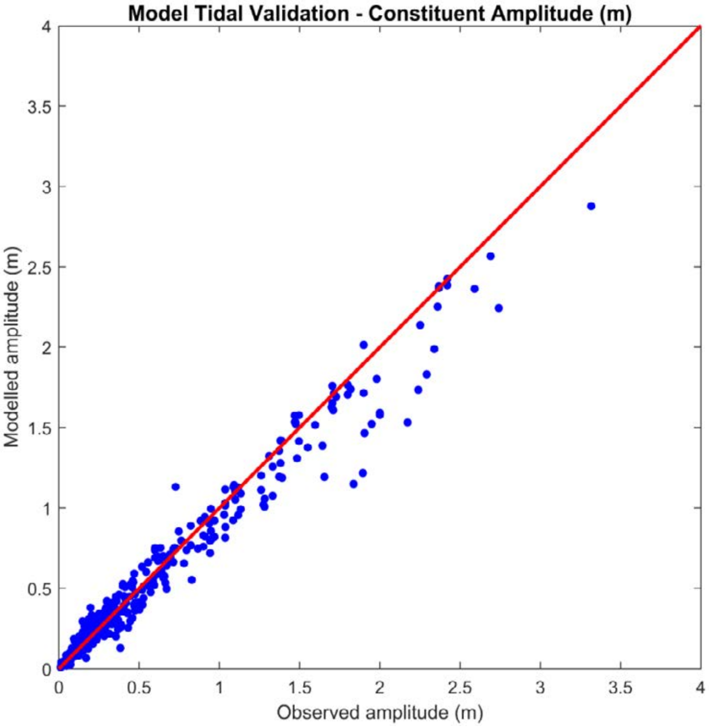

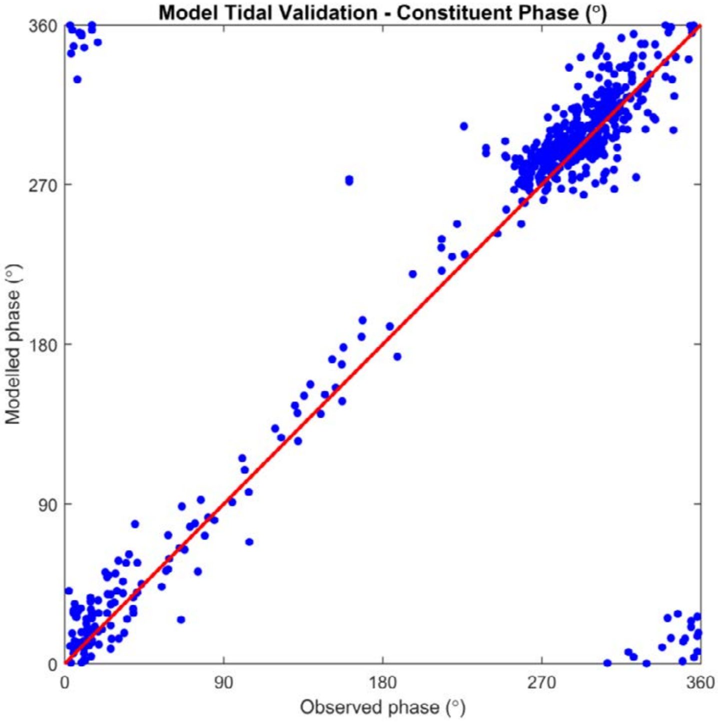

Figure 2.17 **Comparisons between modelled and observed tidal constituent amplitudes (top) and phases (bottom) at all relevant stations (>80) in the HYDROMAP model domain. The red line indicates a 1:1 correlation between the modelled and observed data.**

2.2.1.3.5 Tidal Currents at the Discharge Locations

Figure 2.18, Figure 2.19 and Figure 2.20 show the seasonal distribution of current speeds and directions for the HYDROMAP data points closest to the Torosa FPSO/PLET, Brecknock/Calliance PLET and NRC tie-in PLET locations, respectively. Note that the convention for defining current direction is the direction towards which the current flows.

The current data indicates cyclical tidal flow directions along a northwest-southeast axis at all locations, with maximum speeds of around 0.35 m/s, 0.35 m/s and 0.45 m/s at the Torosa, Brecknock/Calliance and NRC tie-in locations, respectively.

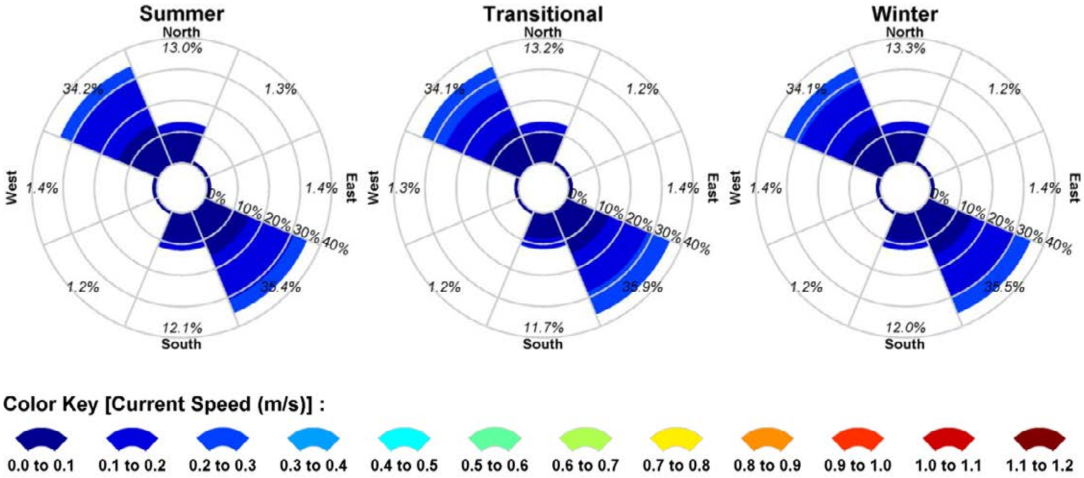

Figure 2.18 Seasonal current distribution (2006-2015, inclusive) derived from the HYDROMAP database near to the proposed Torosa FPSO/PLET locations. The colour key shows the current magnitude, the compass direction provides the direction towards which the current is flowing, and the size of the wedge gives the percentage of the record.

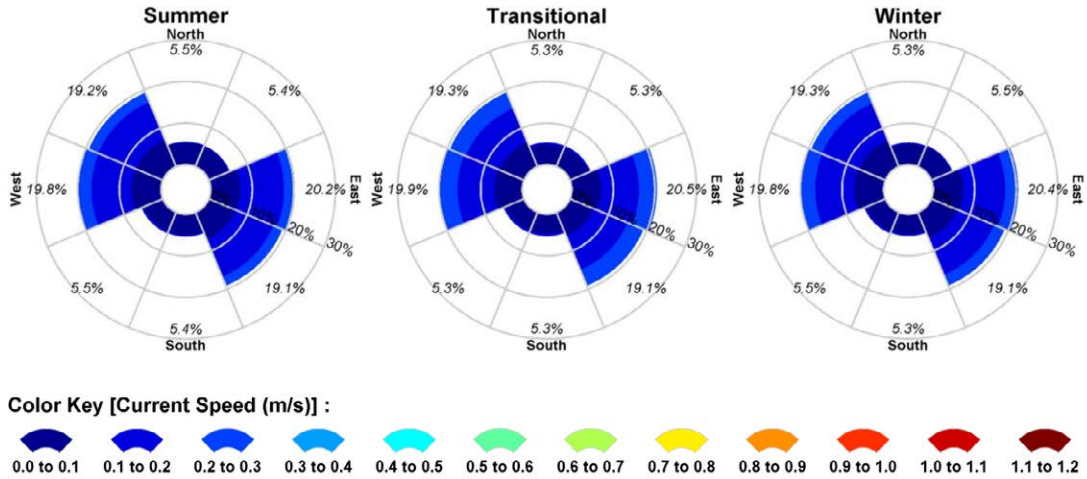

Figure 2.19 Seasonal current distribution (2006-2015, inclusive) derived from the HYDROMAP database near to the proposed Brecknock/Calliance PLET location. The colour key shows the current magnitude, the compass direction provides the direction towards which the current is flowing, and the size of the wedge gives the percentage of the record.

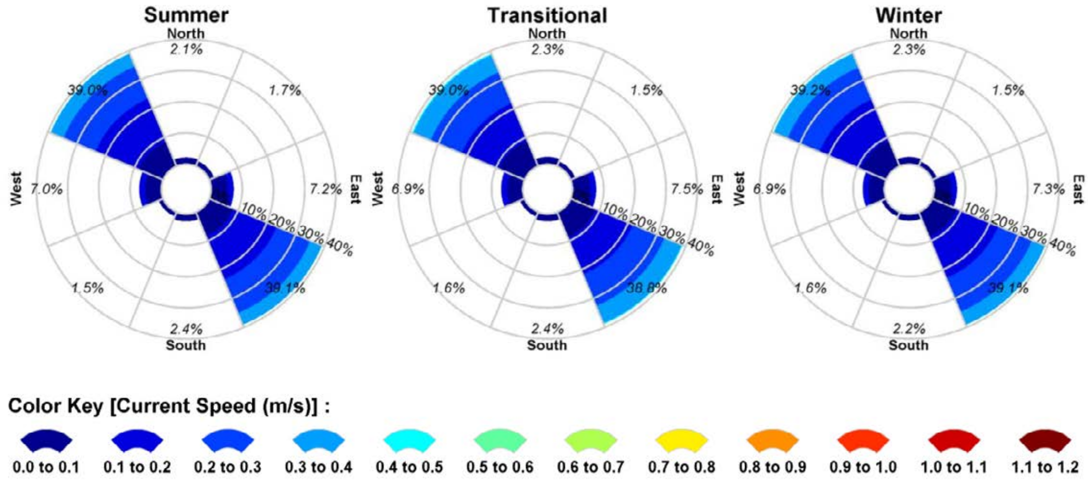

Figure 2.20 Seasonal current distribution (2006-2015, inclusive) derived from the HYDROMAP database near to the proposed NRC tie-in PLET location. The colour key shows the current magnitude, the compass direction provides the direction towards which the current is flowing, and the size of the wedge gives the percentage of the record.

3 MODELLING RESULTS

3.1 Near-Field Modelling

3.1.1 Cooling Water Discharges

3.1.1.1 Overview

In the following sections, information for each of the modelled discharge cases is presented first in a table summarising the predicted plume characteristics in the near-field mixing zone under varying current speeds, and then in further tables summarising the concentrations of chlorine and the amount of dilution at the end of the near-field mixing zone for each season and for the annual period.

Figure 3.1 to Figure 3.4 (note the differing x-axis and y-axis aspect ratios) show the change in average dilution and temperature of the plume at a discharge rate of 720,000 m^3/d and depth of 12 m, under varying seasonal conditions (summer, transitional, winter and annual) and current speeds (weak, medium and strong). The figures show the predicted horizontal distance travelled by the plume before the trapping depth is reached (i.e. before the plume becomes neutrally buoyant).

The results show that due to the momentum of the discharge a turbulent mixing zone is created in the immediate vicinity of the discharge point, which is 12 m below the water surface. Medium and strong currents are shown to increase the extent of the turbulent mixing zone. Following this initial mixing, the positively buoyant plume is predicted to rise in the water column. The plume is predicted to plunge up to 16 m below the sea surface in all seasons. Increased ambient current strengths are shown to increase the horizontal distance travelled by the plume from the discharge point.

Table 3.1 shows the predicted plume characteristics for the varying seasonal conditions and current speeds. High annualised currents push the plume to a maximum horizontal distance of 42.4 m for the Case C discharge. The annualised maximum diameter of the plume at the end of the near-field zone is forecast to be 15.2 m for the Case C discharge.

For all seasons, the primary factor influencing dilution of the plume is the strength of the ambient current. Weak currents allow the plume to reach the trapping depth closer to the discharge point, which slows the rate of dilution (Table 3.1). The annualised average dilution levels of the plume upon reaching the trapping depth under medium currents are predicted to be 1:13.5 for Case C. Additionally, the annualised minimum dilution levels of the plume (i.e. dilution of the plume centreline) upon encountering the trapping depth under medium currents are predicted to be 1:6.3 for Case C. Note that these predictions of dilution rely on the persistence of current speed and direction over time and do not account for any build-up of plume concentrations due to slack currents or current reversals.

3.1.2 Produced Water Discharges

3.1.2.1 Overview

In the following sections, information for each of the modelled discharge cases is presented first in a table summarising the predicted plume characteristics in the near-field mixing zone under varying current speeds, and then in further tables summarising the concentrations of total oil, mercury and MEG, and the amount of dilution, at the end of the near-field mixing zone for each season and for the annual period.

Figure 3.5 to Figure 3.12 (note the differing x-axis and y-axis aspect ratios) show the change in average dilution and temperature of the plume under varying discharge rates (5,723 m^3/d and 490 m^3/d), seasonal conditions (summer, transitional, winter and annual), and current speeds (weak, medium and strong). The figures show the predicted horizontal distance travelled by the plume before the trapping depth is reached (i.e. before the plume becomes neutrally buoyant).

The results show that due to the momentum of the discharges a turbulent mixing zone is created in the immediate vicinity of the discharge point, which is 14 m (Cases P and M) below the water surface. Medium and strong currents are shown to increase the extent of the turbulent mixing zone. Following this initial mixing, the positively buoyant plumes are predicted to rise in the water column. In each case, the plume is predicted to rise towards the water surface after the momentum of the initial discharge is lost. Increased ambient current strengths are shown to increase the horizontal distance travelled by the plume from the discharge point.

Table 3.6 and Table 3.11 show the predicted plume characteristics for the varying discharge rates, seasonal conditions, and current speeds. High annualised currents push the plume to a maximum horizontal distance of 43.8 m and 43.4 m for the Case P and M discharges, respectively. The annualised maximum diameter of the plume at the end of the near-field zone is forecast to be 11.7 m for Case P and 8.0 m for Case M.

For all combinations of discharge case and season, the primary factor influencing dilution of the plume is the strength of the ambient current. Weak currents allow the plume to reach the trapping depth closer to the discharge point, which slows the rate of dilution (Table 3.6 and Table 3.11). The annualised average dilution levels of the plume upon reaching the trapping depth under medium currents are predicted to be 1:204 for Case P and 1:1,222 for Case M. Additionally, the annualised minimum dilution levels of the plume (i.e. dilution of the plume centreline) upon encountering the trapping depth under medium currents are predicted to be 1:70 for Case P and 1:323 for Case M. Note that these predictions of dilution rely on the persistence of current speed and direction over time and do not account for any build-up of plume concentrations due to slack currents or current reversals.

3.1.3 Hydrotest Discharges

3.1.3.1 Overview

In the following sections, information for each of the modelled discharge cases is presented first in a table summarising the predicted plume characteristics in the near-field mixing zone under varying current speeds, and then in further tables summarising the concentrations of biocide and the amount of dilution at the end of the near-field mixing zone for each season and for the annual period.

Figure 3.13 to Figure 3.28 (note the differing x-axis and y-axis aspect ratios) show the change in average dilution and temperature of the plume at a discharge rate of 25 m^3/min, under varying discharge depths (117 m, 461 m and 539 m), seasonal conditions (summer, transitional, winter and annual) and current speeds (weak, medium and strong). The figures show the predicted horizontal distance travelled by the plume before the trapping depth is reached (i.e. before the plume becomes neutrally buoyant).

The results show that due to the momentum of the discharges a turbulent mixing zone is created in the immediate vicinity of the discharge points, which are 117 m (Case H1), 461 m (Cases H2 and H3b) and 539 m (Case H3a) below the water surface. Following this initial mixing, the near neutrally buoyant plumes are predicted to travel laterally in the water column. Increased ambient current strengths are shown to increase the horizontal distance travelled by the plume from the discharge point.

Table 3.16, Table 3.21, Table 3.26 and Table 3.31 show the predicted plume characteristics for the varying discharge depths, seasonal conditions and current speeds. High annualised currents push the plume to a maximum horizontal distance of 64.5 m, 101.2 m, 103.0 m and 101.2 m for the Case H1, H2, H3a and H3b discharges, respectively. The annualised maximum diameter of the plume at the end of the near-field zone is forecast to be 15.8 m for Case H1, 23.4 m for Case H2, 24.0 m for Case H3a and 23.4 m for Case H3b.

For all combinations of discharge case and season, the primary factor influencing dilution of the plume is the strength of the ambient current. The annualised average dilution levels of the plume upon reaching the trapping depth under medium currents are predicted to be 1:111 for Case H1, 1:166 for Case H2, 1:172 for Case H3a and 1:166 for Case H3b. Additionally, the annualised minimum dilution levels of the plume (i.e. dilution of the plume centreline) upon encountering the trapping depth under medium currents are predicted to be 1:41 for Case H1, 1:62 for Case H2, 1:65 for Case H3a and 1:62 for Case H3b. Note that these predictions of dilution rely on the persistence of current speed and direction over time and do not account for any build-up of plume concentrations due to slack currents or current reversals.

3.2 Far-Field Modelling

3.2.1 Overview

It is important to note that near-field and far-field modelling are used to describe different processes and scales of effect, and therefore the far-field modelling results will not necessarily correspond to the outcomes at the end of the near-field mixing zone for any given discharge scenario. The far-field results included episodes of pooling of the discharge plume under weak currents, which caused lower dilutions (higher concentrations) further from the discharge location when the pooled plume was advected away. Episodes of recirculation – where the plume moved back under the discharge at some later time due to the oscillatory nature of the tide – were also observed, compounding the pooling effect and further lowering the dilution values.

3.2.2 Interpretation of Percentile Dilution Contours

For each of the modelled discharge cases, the results for all simulations were combined and a statistical analysis performed to produce percentile contours of dilution. In the following sections, outcomes based on 95th percentile dilution contours are presented.

Calculation of 95th percentile statistics is a common approach to assessing the impact of dispersing plumes and captures the variability in outcomes, for all but the most ephemeral and extreme forcing conditions, in the data set under consideration. Impact assessment criteria for water quality are often defined using similar statistical indicators.

Note that the percentile figures do not represent the location of a plume at any point in time; they are a statistical and spatial summary of the percentage of time that particular dilution values occur across all replicate simulations and time steps. For example, if the 95th percentile minimum dilution at a particular location in the model domain is predicted as a value of 100, this means that for 95% of the time the dilution level will be higher than 100 and for only 5% of the time the dilution level will be lower than 100. A comparison of instantaneous plume extent snapshots, as shown in Figure 3.29 (CW discharges), Figure 3.41 (PW discharges) and Figure 3.56 (hydrotest discharges), with the percentile images for the corresponding discharge demonstrates the significant difference between an instantaneous snapshot and a cumulative estimate of coverage over several days and many individual simulations.

Dilution contours are calculated from the ratios of dispersing constituent concentrations in the receiving waters to the initial concentration of the constituent in the discharge. Note that this assumes the background concentration of the constituent in the receiving waters is zero and there is no significant biodegradation of the discharged constituent over the short duration of the dispersion process.

Table 3.36 summarises the initial concentrations of chlorine, as specified, and the equivalent dispersed concentrations required to yield particular dilution levels (1:100, 1:200 and 1:400).

Table 3.36 Initial concentrations of chlorine and equivalent concentrations at example dilution levels.

Parameter	Chlorine Concentration (ppm)	
Initial concentration in discharge	0.2	0.5
Initial concentration in receiving waters	0.0	
Concentration at 1:100 dilution	0.002	0.005
Concentration at 1:200 dilution	0.001	0.0025
Concentration at 1:400 dilution	0.0005	0.00125

Table 3.37 summarises the initial concentrations of total oil (including BTEX), mercury and MEG, as specified, and the equivalent dispersed concentrations required to yield particular dilution levels (1:100, 1:200 and 1:400).

Table 3.37 Initial concentrations of total oil, mercury and MEG, and equivalent concentrations at example dilution levels.

Parameter	Total Oil Concentration (mg/L)	Mercury Concentration (mg/L)	MEG Concentration (mg/L)
Initial concentration in discharge	30.0	0.03	79,000.0
Initial concentration in receiving waters	0.0	0.00	0.0
Concentration at 1:100 dilution	0.3	0.0003	790.0
Concentration at 1:200 dilution	0.15	0.00015	395.0
Concentration at 1:400 dilution	0.075	0.000075	197.5

Table 3.38 summarises the initial concentrations of biocide, as specified, and the equivalent dispersed concentrations required to yield particular dilution levels (1:100, 1:200, 1:400 and 1:10,000).

Table 3.38 Initial concentrations of biocide and equivalent concentrations at example dilution levels.

Parameter	Biocide Concentration (ppm)
Initial concentration in discharge	600.0
Initial concentration in receiving waters	0.0
Concentration at 1:100 dilution	6.0
Concentration at 1:200 dilution	3.0
Concentration at 1:400 dilution	1.5
Concentration at 1:10,000 dilution	0.06

These concentrations may be useful to consider when interpreting the contour plots of percentile dilutions.

3.2.3 Cooling Water Discharges

3.2.3.1 General Observations

Figure 3.29 shows example time series snapshots of predicted dilutions during a single simulation at 3-hour intervals from 01:00 to 16:00 on 20th January 2013. This simulation – selected merely to be representative of typical conditions – considers the Case C discharge at 12 m BMSL. The spatially-varying orientation of the plume with the currents and the rapidly-varying nature of the concentrations around the source can be observed. The snapshots also show the combined effect of the tide and the drift currents, with a clear tidal oscillation.

These snapshots illustrate that the dilutions (and in turn concentrations) become more variable over time because of changes in current speed and direction. Higher dilutions (lower concentrations) are predicted during periods of increased current speed, whereas patches of lower dilutions (higher concentrations) tend to accumulate during the turning of the tide or during periods of weak drift currents. During prolonged periods of lowered current speed, the plume has a more continuous appearance, with higher-concentration patches moving as a unified group.

The snapshots in Figure 3.29 show a clear separation between a contiguous plume emanating from the source and a more distant detached plume. The detached plume contains higher constituent concentrations than the surrounding waters, which is the result of a recirculation episode at an earlier time in the discharge where the existing plume passed over the source once more. Within the main plume, another sub-plume likely to break off in the future can be seen.

These findings agree with the research of King & McAllister (1997, 1998) who noted that concentrations within effluent plumes generated by an offshore platform were patchy and likely to peak around the reversal of the tides.

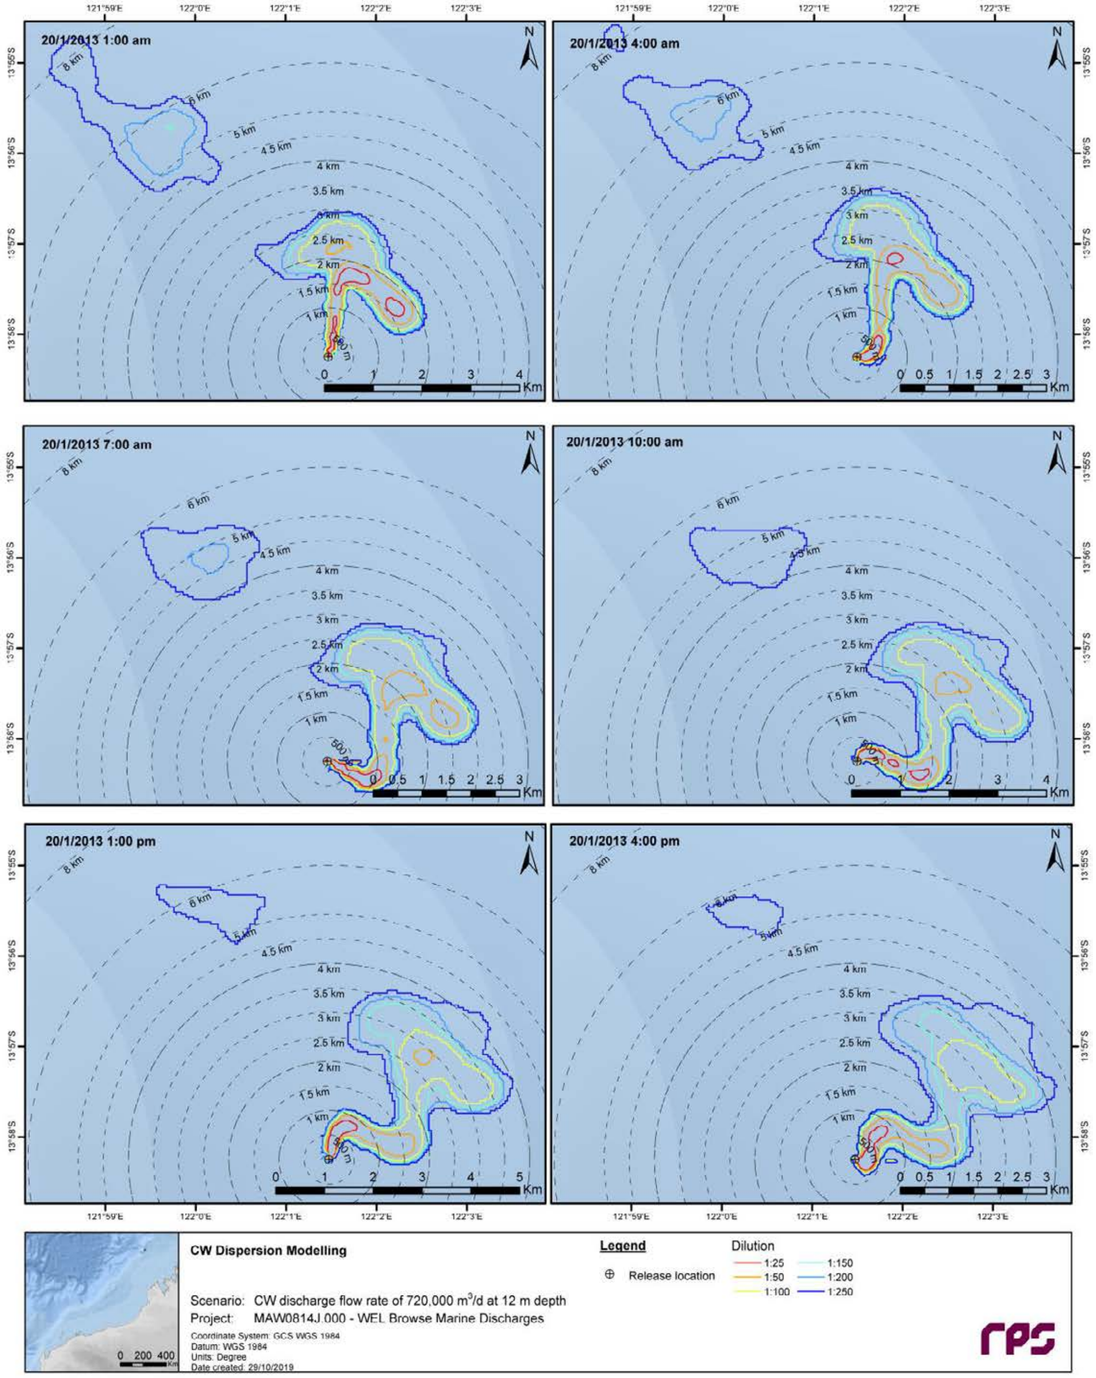

Figure 3.29 Snapshots of predicted dilution levels, at 3-hour intervals from 01:00 to 16:00 on 20th January 2013, for Case C (12 m depth discharge at 720,000 m^3/d flow rate).

3.2.3.2 Seasonal Analysis

3.2.3.2.1 Summary

The model outputs over the ten-year hindcast period (2006-2015) were combined and analysed on a seasonal basis (summer, transitional and winter). This approach assists with identifying the potential exposure to surrounding sensitive receptors whilst considering inter-annual variability in ocean current conditions.

Table 3.39 summarises for Case C the average and minimum dilution achieved at specific radial distances from the discharge location – as well as at or within the Scott Reef area defined by the 3 nm State water boundary – for each season and percentile.

Table 3.40 provides for Case C a summary of the maximum distances from the discharge location to achieve an example dilution level of 1:100 for each season and percentile. The results indicate that the release of effluent under all seasonal conditions results in slow dispersion within the ambient environment. A 1:100 dilution is achieved within an area of influence ranging from 3.7-4.2 km at the 95th percentile.

Table 3.41 provides for Case C a summary of the total areas of coverage for the 1:100 dilution contour for each season and percentile. The area of exposure defined by the relevant dilution contour is predicted to reach a maximum value of 1.9-2.3 km^2 at the 95th percentile.

Table 3.42 provides for Case C a summary of the maximum depths from the discharge location to achieve 1:100 dilution for each season and percentile. The maximum depth is observed in summer and winter, with a prediction of 20 m.

Table 3.43 provides a summary of the maximum distances from the discharge location and total areas of coverage to achieve an example 3 °C plume-ambient temperature differential for each season and percentile. This differential is forecast to be met within 120 m at the 95th percentile.

For Case C, the aggregated spatial extents of the minimum dilutions for each season at the 95th percentile are presented in Figure 3.30 to Figure 3.32. Note that the contours represent the lowest predicted dilution (highest concentration) at any given time step through the water column and do not consider frequency or duration. The discharged plumes are predicted to travel in predominantly northerly directions during summer and transitional months, and south-easterly directions during winter.

The results presented assume that no processes other than dilution would reduce the source concentrations over time, and therefore can be considered as conservative outcomes.

For Case C, Figure 3.33 to Figure 3.35 show the aggregated spatial extents of the maximum plume-ambient temperature differential for each season at the 95th percentile.

Seasonal water column cross-section figures of 95th percentile dilution, extracted along perpendicular transects running through the origin point of the discharge (one of which is broadly aligned with the principal travel direction of the plume), are presented in Figure 3.36 to Figure 3.38. Although initially slightly positively buoyant due to its elevated temperature, the discharged plume is predicted to achieve density equilibrium with the receiving waters relatively quickly. The plume centreline – where highest concentrations and lowest dilutions are found – will tend to remain entrained more than 10 m below the water surface.

3.2.3.2.2 Discharge Case C: Flow Rate of 720,000 m^3/day at 12 m Depth

Table 3.39 Average and minimum dilutions (1:x) achieved at specific radial distances from the CW discharge location in each season for Case C (12 m depth discharge at 720,000 m^3/d flow rate).

3.2.3.3 Annualised Analysis

3.2.3.3.1 Summary

The model outputs for each season (summer, transitional and winter) over the ten-year hindcast period (2006-2015) were combined and analysed on an annualised basis.

Table 3.44 summarises for Case C the average and minimum dilution achieved at specific radial distances from the discharge location – as well as at or within the Scott Reef area defined by the 3 nm State water boundary – for each percentile over the annual period.

The minimum level of dilution achieved at or within the Scott Reef receptor at the 95th percentile in any season is predicted to be 1:125 for Case C.

Table 3.45 provides for Case C a summary of the annualised maximum distances from the discharge location to achieve an example dilution level of 1:100 for each percentile. The results indicate that the release of effluent under all seasonal conditions results in slow dispersion within the ambient environment. Dilution to reach the 1:100 level at the 95th percentile – this being the maximum spatial extent of the relevant dilution contour from the discharge location in any season – is achieved within a maximum area of influence of 4.2 km.

Table 3.46 provides for Case C a summary of the annualised total areas of coverage for the 1:100 dilution contour for each percentile. The area of exposure defined by the relevant dilution contour is predicted to reach a maximum value of 3.7 km^2 at the 95th percentile across all seasons.

Table 3.47 provides a summary of the annualised maximum distances from the discharge location and total areas of coverage to achieve an example 3 °C plume-ambient temperature differential for each percentile. This differential is forecast to be met within 120 m at the 95th percentile across all seasons.

For Case C, the aggregated spatial extents of the minimum dilutions at the 95th percentile are presented in Figure 3.39. Note that the contours represent the lowest predicted dilution (highest concentration) at any given time step through the water column and do not consider frequency or duration.

The results presented assume that no processes other than dilution would reduce the source concentrations over time, and therefore can be considered as conservative outcomes.

For Case C, Figure 3.40 shows the aggregated spatial extents of the maximum plume-ambient temperature differential at the 95th percentile.

3.2.4 Produced Water Discharges

3.2.4.1 General Observations

Figure 3.41 shows example time series snapshots of predicted dilutions during a single simulation at 3-hour intervals from 22:00 on 9th December 2007 to 13:00 on 10th December 2007. This simulation – selected merely to be representative of typical conditions – considers the Case P discharge at 14 m BMSL. The spatially-varying orientation of the plume with the currents and the rapidly-varying nature of the concentrations around the source can be observed. The snapshots also show the combined effect of the tide and the drift currents, with a clear tidal oscillation.

These snapshots illustrate that the dilutions (and in turn concentrations) become more variable over time because of changes in current speed and direction. Higher dilutions (lower concentrations) are predicted during periods of increased current speed, whereas patches of lower dilutions (higher concentrations) tend to accumulate during the turning of the tide or during periods of weak drift currents. During prolonged periods of lowered current speed, the plume has a more continuous appearance, with higher-concentration patches moving as a unified group.

The snapshots in Figure 3.41 show a clear “string of pearls” pattern, where a relatively thin plume emanating from the source is punctuated with higher-concentration plume patches which separate over time from the contiguous plume. This pattern is attributable to periodic tide reversals which cause the existing plume to repeatedly pass over the source.

These findings agree with the research of King & McAllister (1997, 1998) who noted that concentrations within effluent plumes generated by an offshore platform were patchy and likely to peak around the reversal of the tides.

PW Dispersion Modelling

Scenario: PW discharge flow rate of 5,723 m^3/d at 14 m depth
Project: MAW0814J.000 - WEL Browse Marine Discharges
Coordinate System: GCS WGS 1984
Datum: WGS 1984
Units: Degree
Date created: 30/10/2019

Figure 3.41 Snapshots of predicted dilution levels, at 3-hour intervals from 22:00 on 9th December 2007 to 13:00 on 10th December 2007, for Case P (14 m depth discharge at 5,723 m^3/d flow rate).

3.2.4.2 Seasonal Analysis

3.2.4.2.1 Summary

The model outputs over the ten-year hindcast period (2006-2015) were combined and analysed on a seasonal basis (summer, transitional and winter). This approach assists with identifying the potential exposure to surrounding sensitive receptors whilst considering inter-annual variability in ocean current conditions.

Table 3.48 and Table 3.52 summarise, for Cases P and M respectively, the average and minimum dilution achieved at specific radial distances from the discharge location – as well as at or within the Scott Reef area defined by the 3 nm State water boundary – for each season and percentile.

Table 3.49 provides for Case P a summary of the maximum distances from the discharge location to achieve an example dilution level of 1:300 for each season and percentile. The results indicate that the release of effluent under all seasonal conditions results in rapid dispersion within the ambient environment. A 1:300 dilution is achieved within an area of influence ranging from 0.6-0.9 km at the 95th percentile.

Table 3.50 provides for Case P a summary of the total areas of coverage for the 1:300 dilution contour for each season and percentile. The area of exposure defined by the relevant dilution contour is predicted to reach a maximum value of 0.4-0.6 km^2 at the 95th percentile.

Table 3.51 provides for Case P a summary of the maximum depths from the discharge location to achieve 1:300 dilution for each season and percentile. The maximum depth is observed in winter, with a prediction of 19 m.

For Cases P and M, the aggregated spatial extents of the minimum dilutions for each season at the 95th percentile are presented in Figure 3.42 to Figure 3.44 and Figure 3.48 to Figure 3.50, respectively. Note that the contours represent the lowest predicted dilution (highest concentration) at any given time step through the water column and do not consider frequency or duration. The discharged plumes are predicted to travel in predominantly northerly directions during summer and transitional months, and south-easterly directions during winter.

The results presented assume that no processes other than dilution would reduce the source concentrations over time, and therefore can be considered as conservative outcomes.

Seasonal water column cross-section figures of 95th percentile dilution, extracted along perpendicular transects running through the origin point of the discharge (one of which is broadly aligned with the principal travel direction of the plume), are presented in Figure 3.45 to Figure 3.47 (Case P) and Figure 3.51 to Figure 3.53 (Case M). Although initially buoyant due to elevated temperature, the discharged plumes are predicted to quickly achieve density equilibrium with the receiving waters and rapidly dilute. This is particularly evident for the Case M discharge. The Case P plume centreline – where highest concentrations and lowest dilutions are found – will tend to remain entrained in a thin layer around 15 m below the water surface.

3.2.4.2.2 Discharge Case P: Flow Rate of 5,723 m^3/day at 14 m Depth

Table 3.48 Average and minimum dilutions (1:x) achieved at specific radial distances from the PW discharge location in each season for Case P (14 m depth discharge at 5,723 m^3/d flow rate).

Table 3.49 **Maximum distance from the PW discharge location to achieve 1:300 dilution in each season for Case P (14 m depth discharge at 5,723 m^3/d flow rate).**

Percentile	Season	Maximum distance (m) from discharge location to achieve given dilution
95th	Summer	699
	Transitional	584
	Winter	948
99th	Summer	2,576
	Transitional	1,883
	Winter	3,607
100th	Summer	9,349
	Transitional	10,493
	Winter	10,493

Table 3.50 **Total area of coverage for 1:300 dilution in each season for Case P (14 m depth discharge at 5,723 m^3/d flow rate).**

Percentile	Season	Total area (km^2) of coverage for given dilution
95th	Summer	0.47
	Transitional	0.40
	Winter	0.62
99th	Summer	4.36
	Transitional	3.57
	Winter	5.50
100th	Summer	37.52
	Transitional	54.79
	Winter	36.23

Table 3.51 **Maximum depth from the PW discharge location to achieve 1:300 dilution in each season for Case P (14 m depth discharge at 5,723 m^3/d flow rate).**

Season	Maximum depth (m) from discharge location to achieve given dilution
Summer	18
Transitional	18
Winter	19

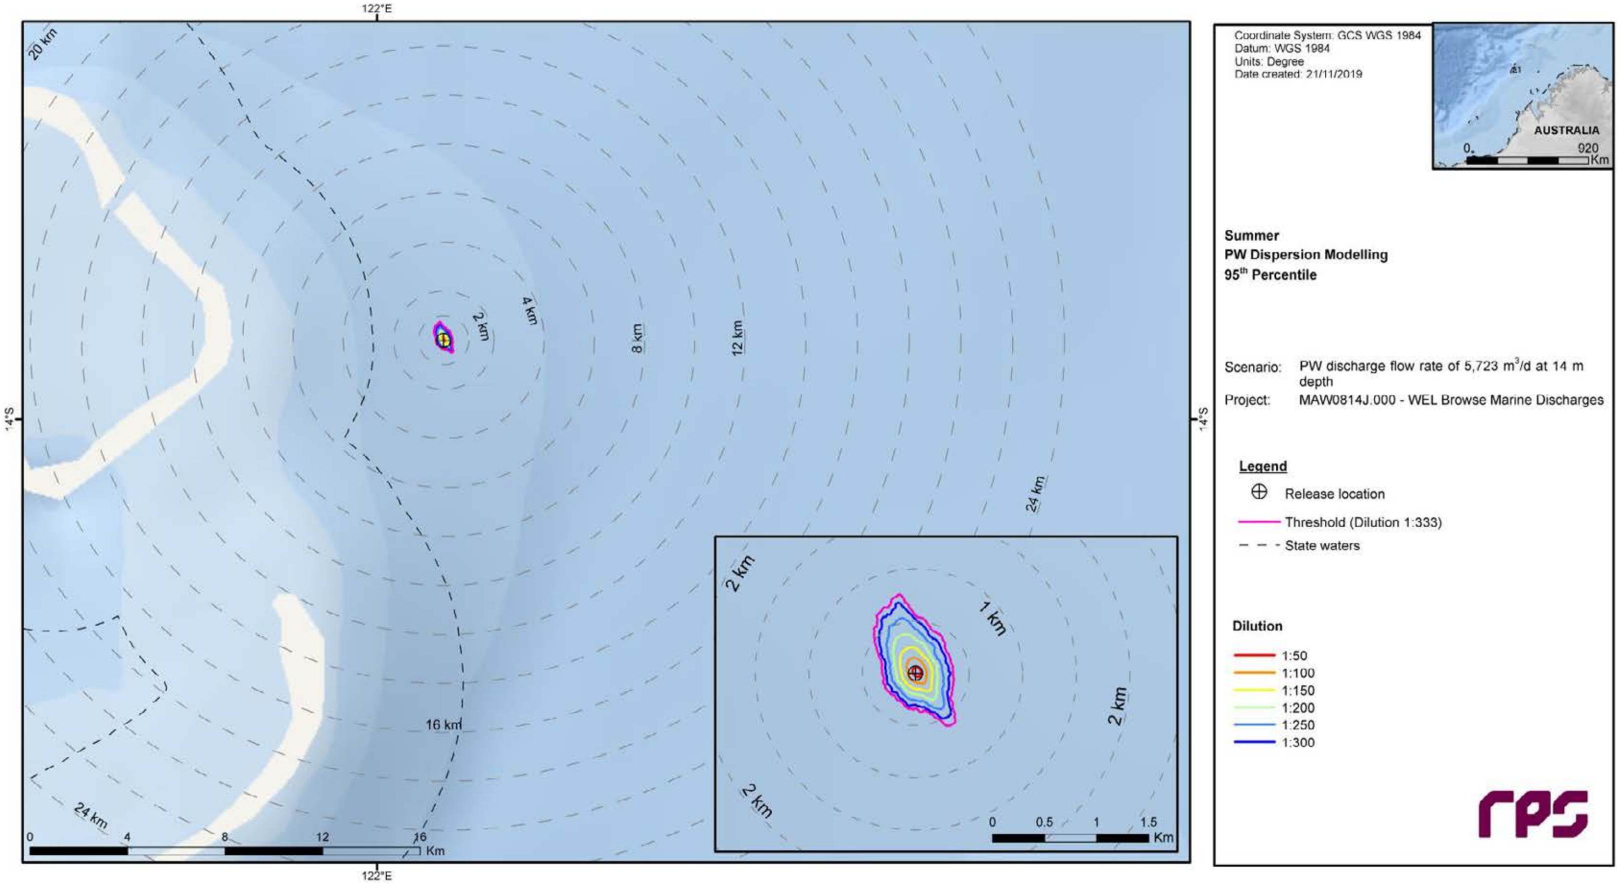

Figure 3.42 Predicted minimum dilutions at the 95th percentile under summer conditions for Case P (14 m depth discharge at 5,723 m^3/d flow rate).

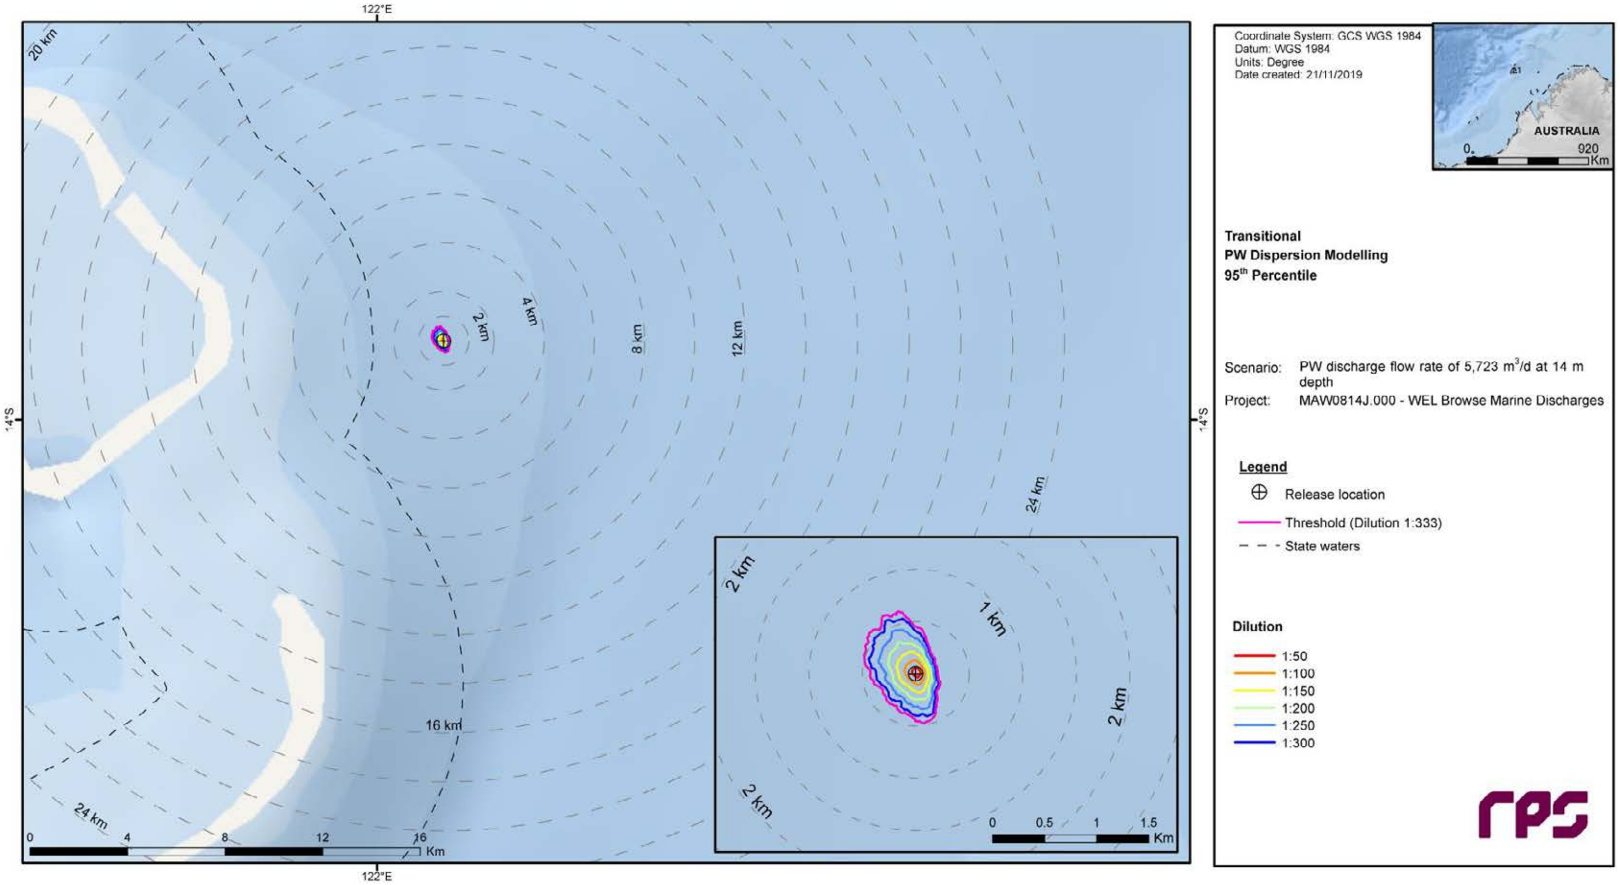

Figure 3.43 Predicted minimum dilutions at the 95th percentile under transitional conditions for Case P (14 m depth discharge at 5,723 m^3/d flow rate).

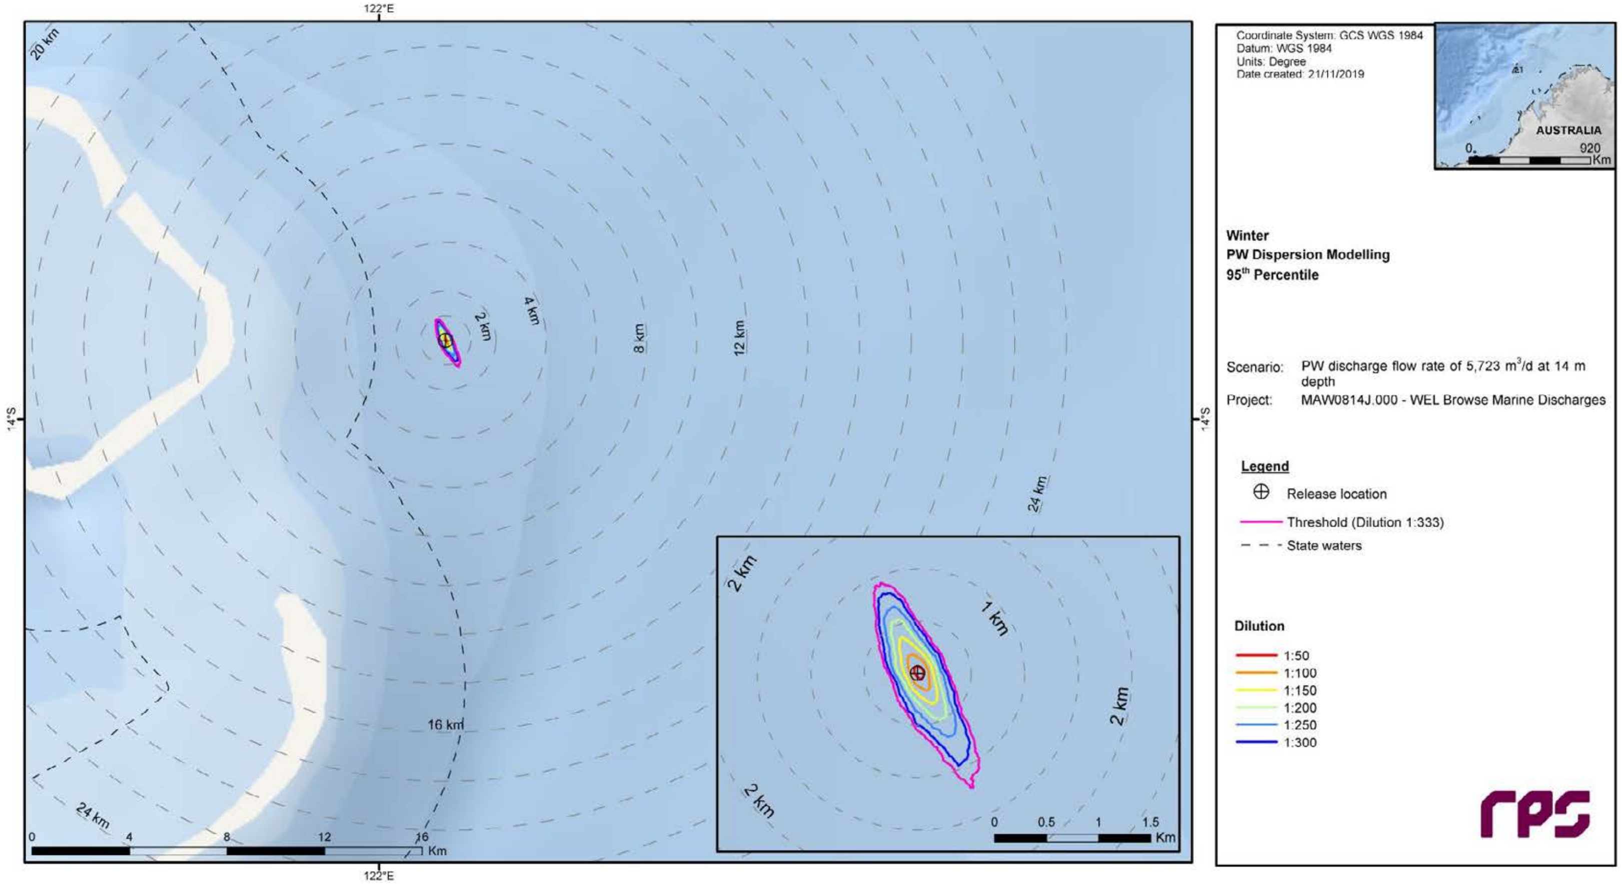

Figure 3.44 Predicted minimum dilutions at the 95th percentile under winter conditions for Case P (14 m depth discharge at 5,723 m^3/d flow rate).

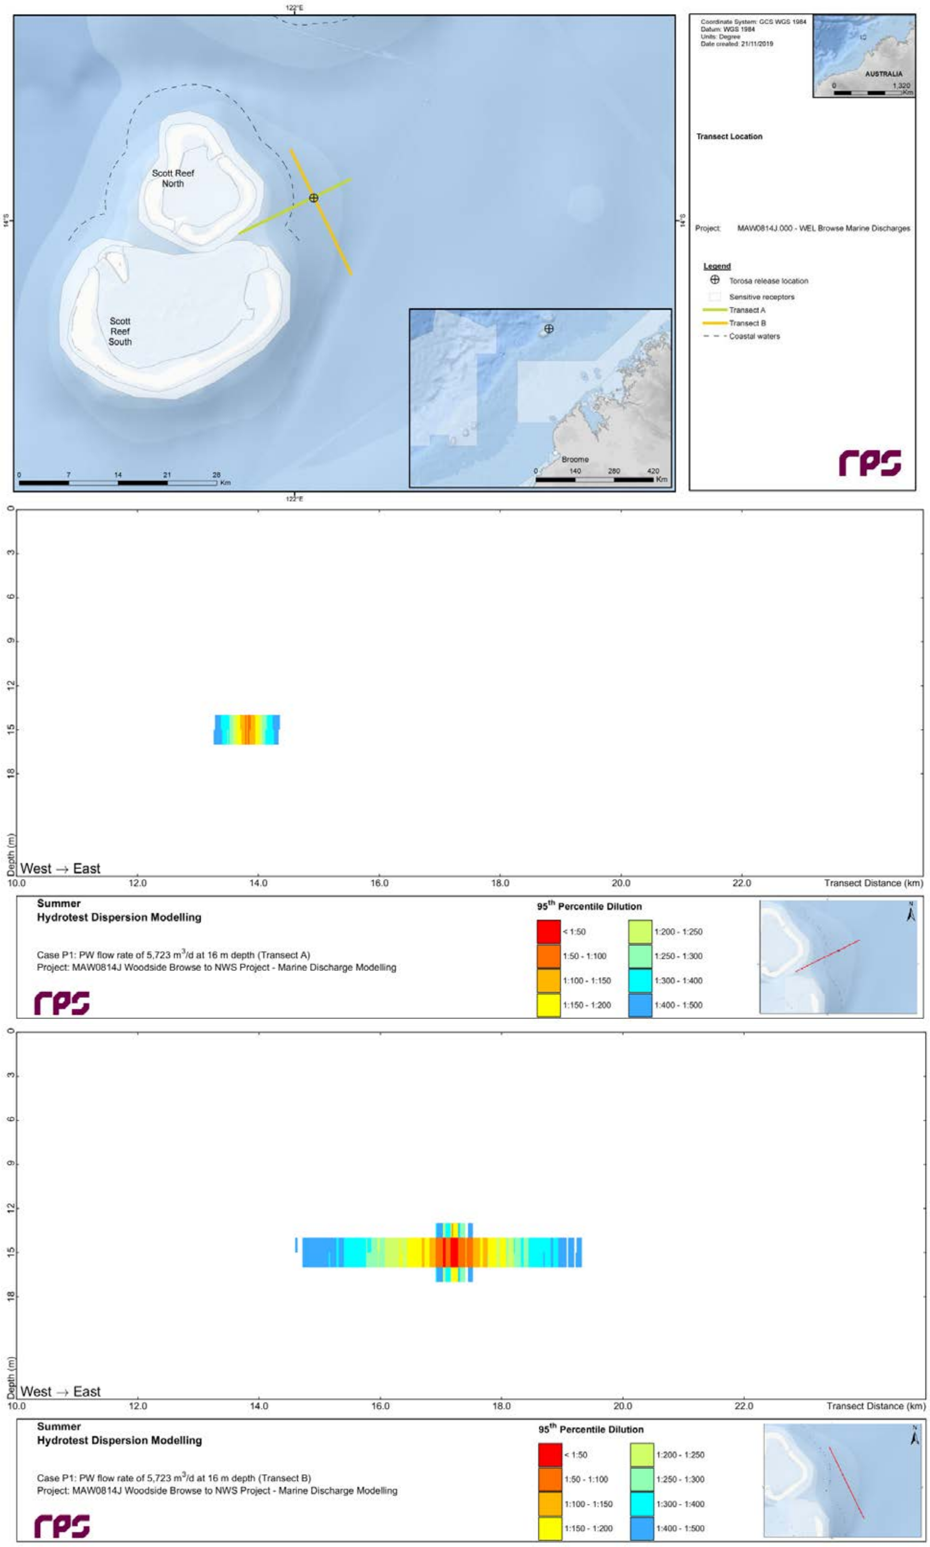

Figure 3.45 Vertical cross-section plots of predicted minimum dilutions at the 95th percentile under summer conditions for Case P (14 m depth discharge at 5,723 m^3/d flow rate). Transect locations are shown in the top panel, with transect A shown in the middle panel and transect B shown in the bottom panel. Spatial representation of this data is shown in Figure 3.42.

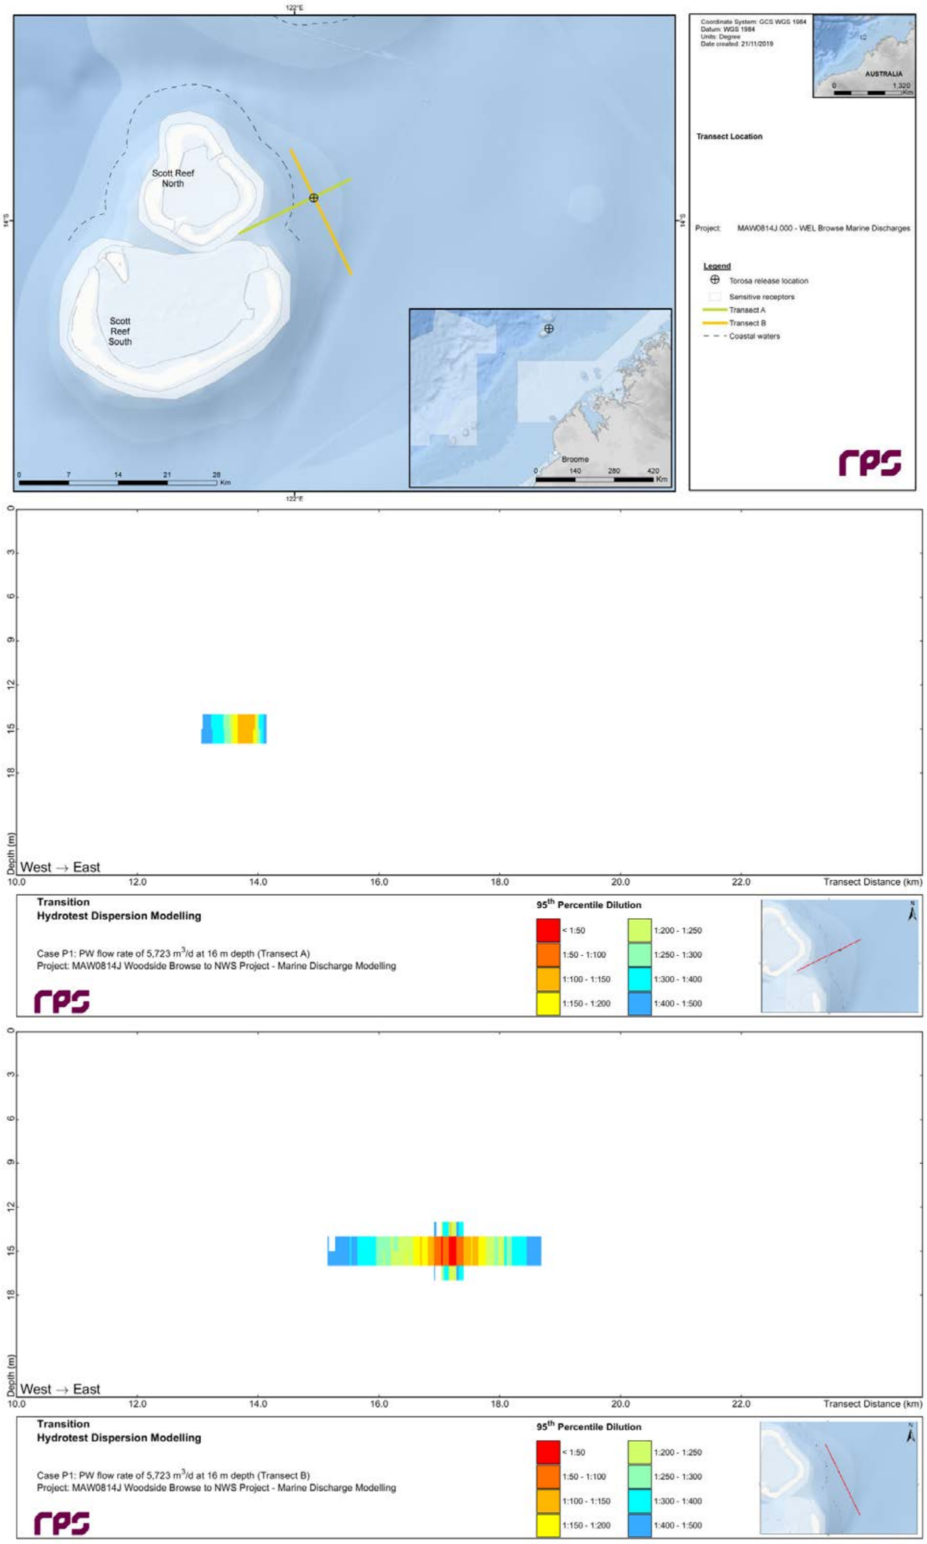

Figure 3.46 Vertical cross-section plots of predicted minimum dilutions at the 95th percentile under transitional conditions for Case P (14 m depth discharge at 5,723 m^3/d flow rate). Transect locations are shown in the top panel, with transect A shown in the middle panel and transect B shown in the bottom panel. Spatial representation of this data is shown in Figure 3.43.

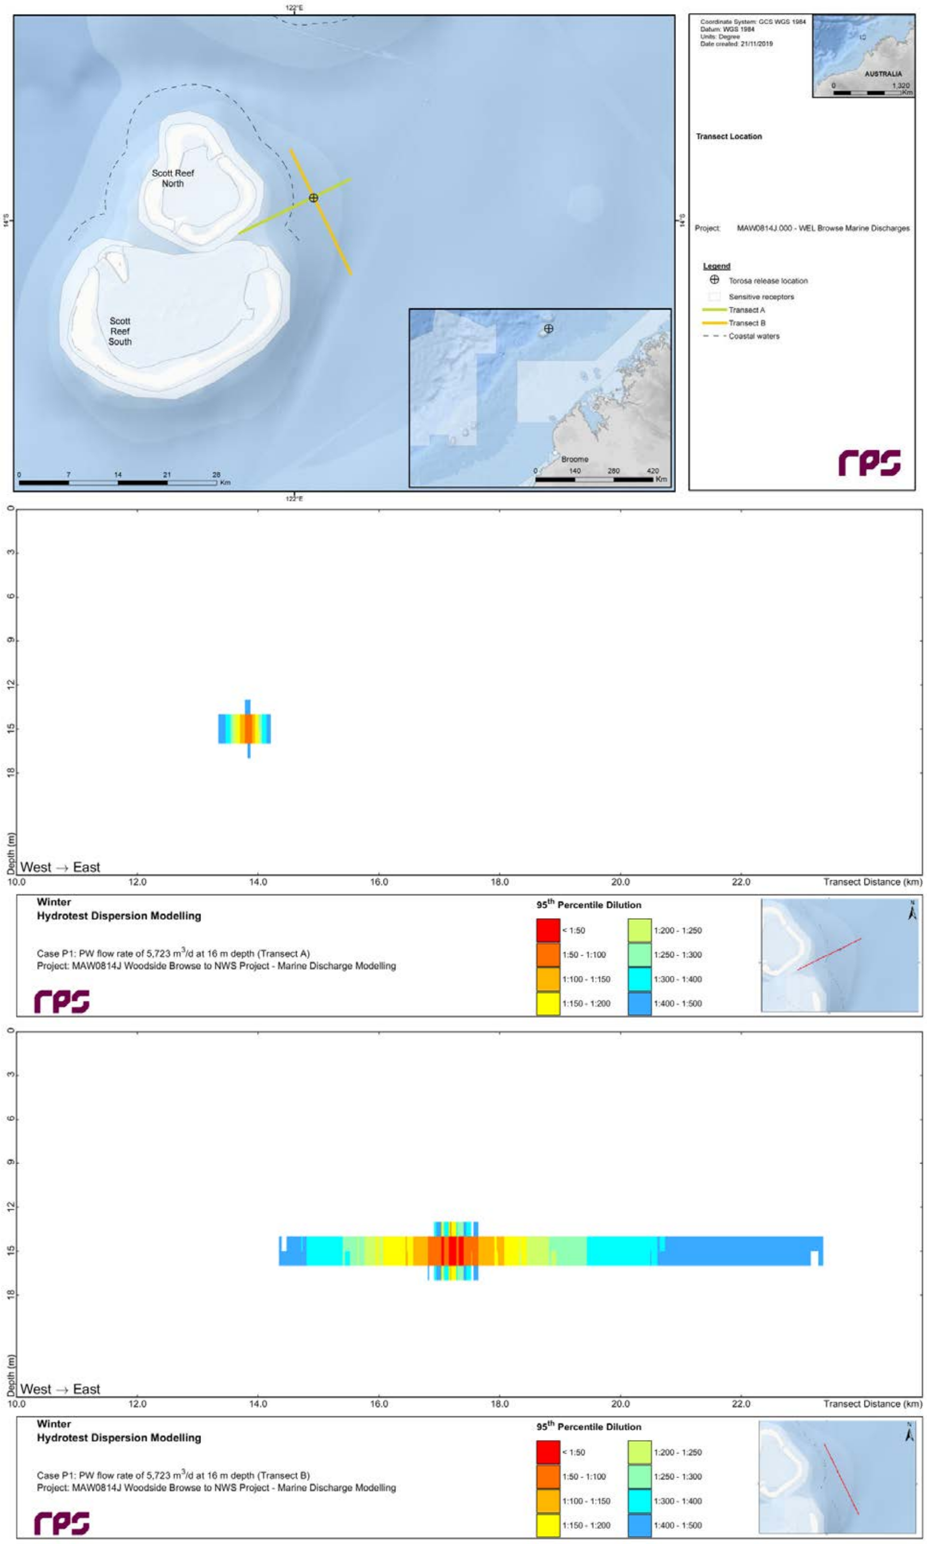

Figure 3.47 Vertical cross-section plots of predicted minimum dilutions at the 95th percentile under winter conditions for Case P (14 m depth discharge at 5,723 m^3/d flow rate). Transect locations are shown in the top panel, with transect A shown in the middle panel and transect B shown in the bottom panel. Spatial representation of this data is shown in Figure 3.44.

3.2.4.2.3 Discharge Case M: Flow Rate of 490 m^3/day at 14 m Depth

Table 3.52 Average and minimum dilutions (1:x) achieved at specific radial distances from the PW discharge location in each season for Case M (14 m depth discharge at 490 m^3/d flow rate).

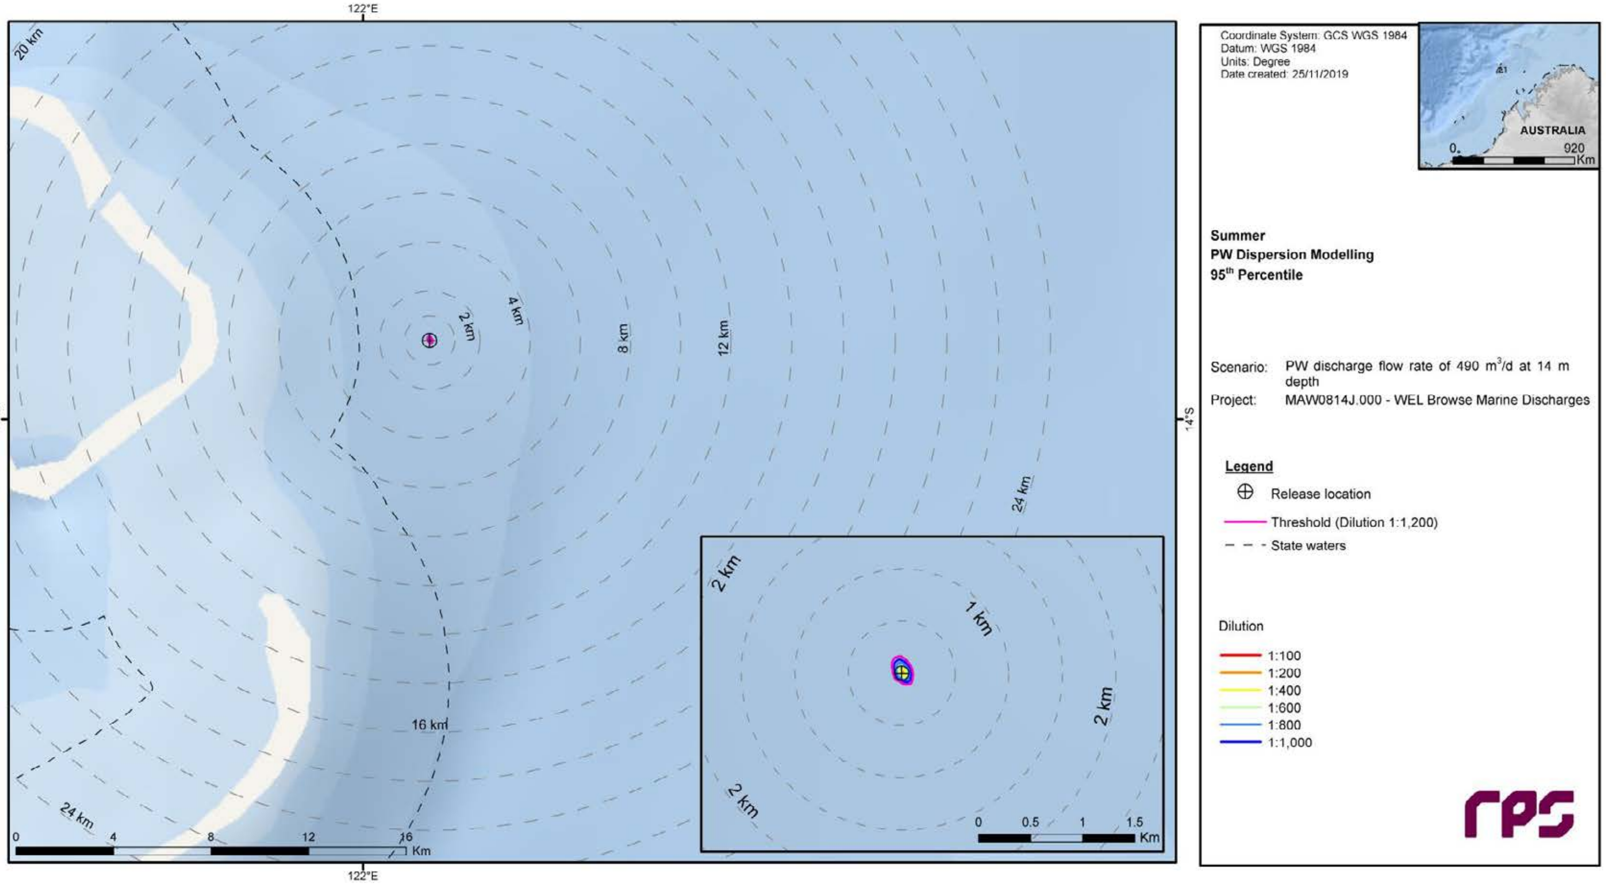

Figure 3.48 Predicted minimum dilutions at the 95th percentile under summer conditions for Case M (14 m depth discharge at 490 m^3/d flow rate).

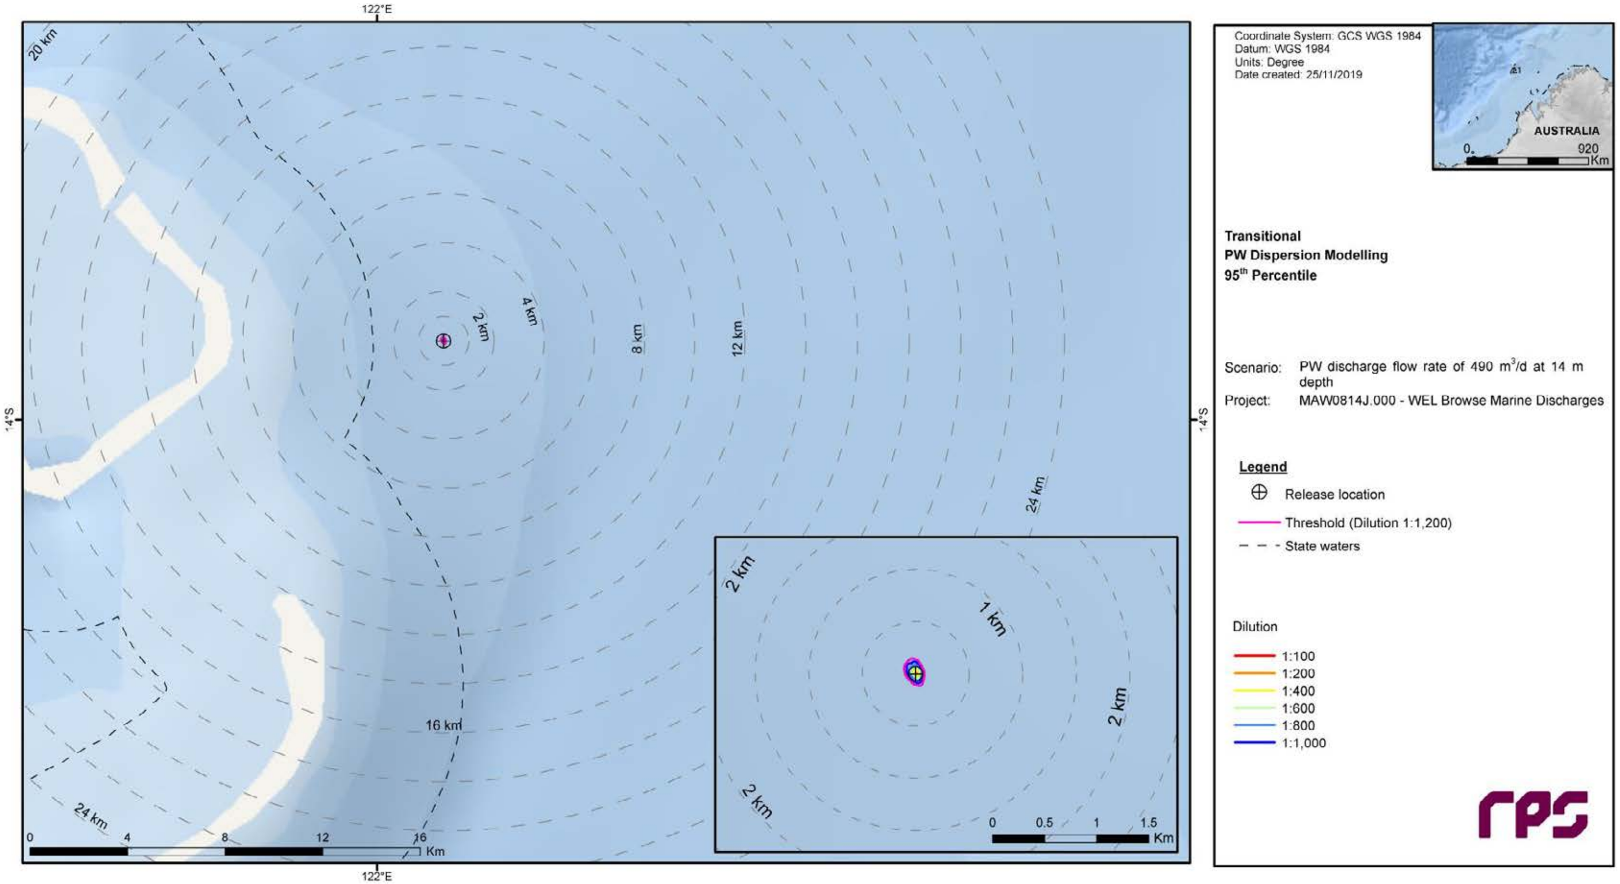

Figure 3.49 Predicted minimum dilutions at the 95th percentile under transitional conditions for Case M (14 m depth discharge at 490 m^3/d flow rate).

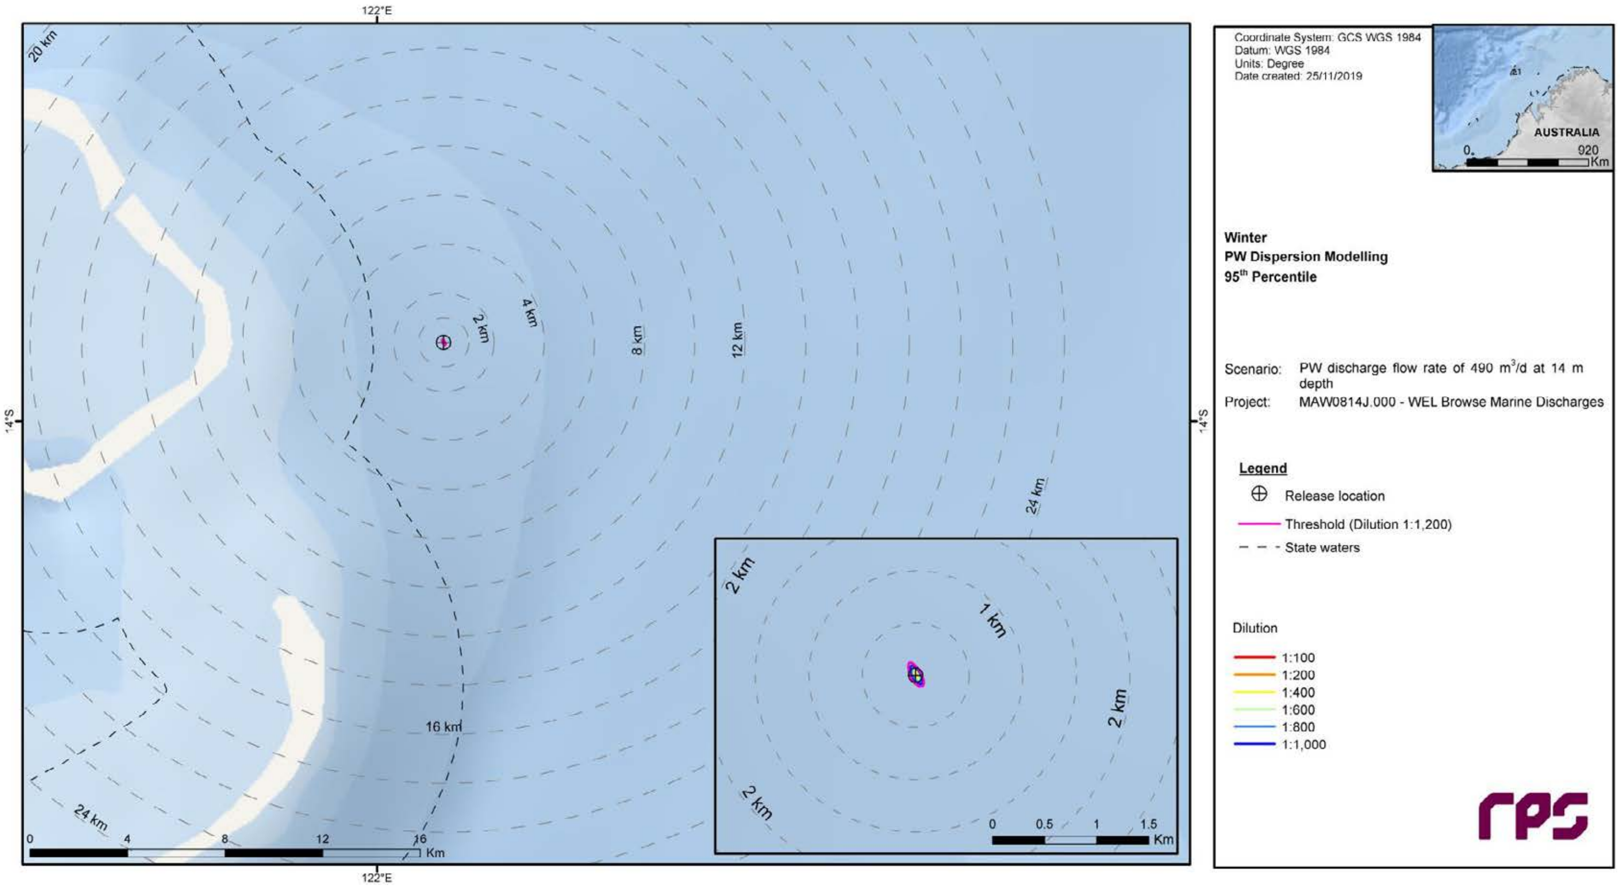

Figure 3.50 Predicted minimum dilutions at the 95th percentile under winter conditions for Case M (14 m depth discharge at 490 m^3/d flow rate).

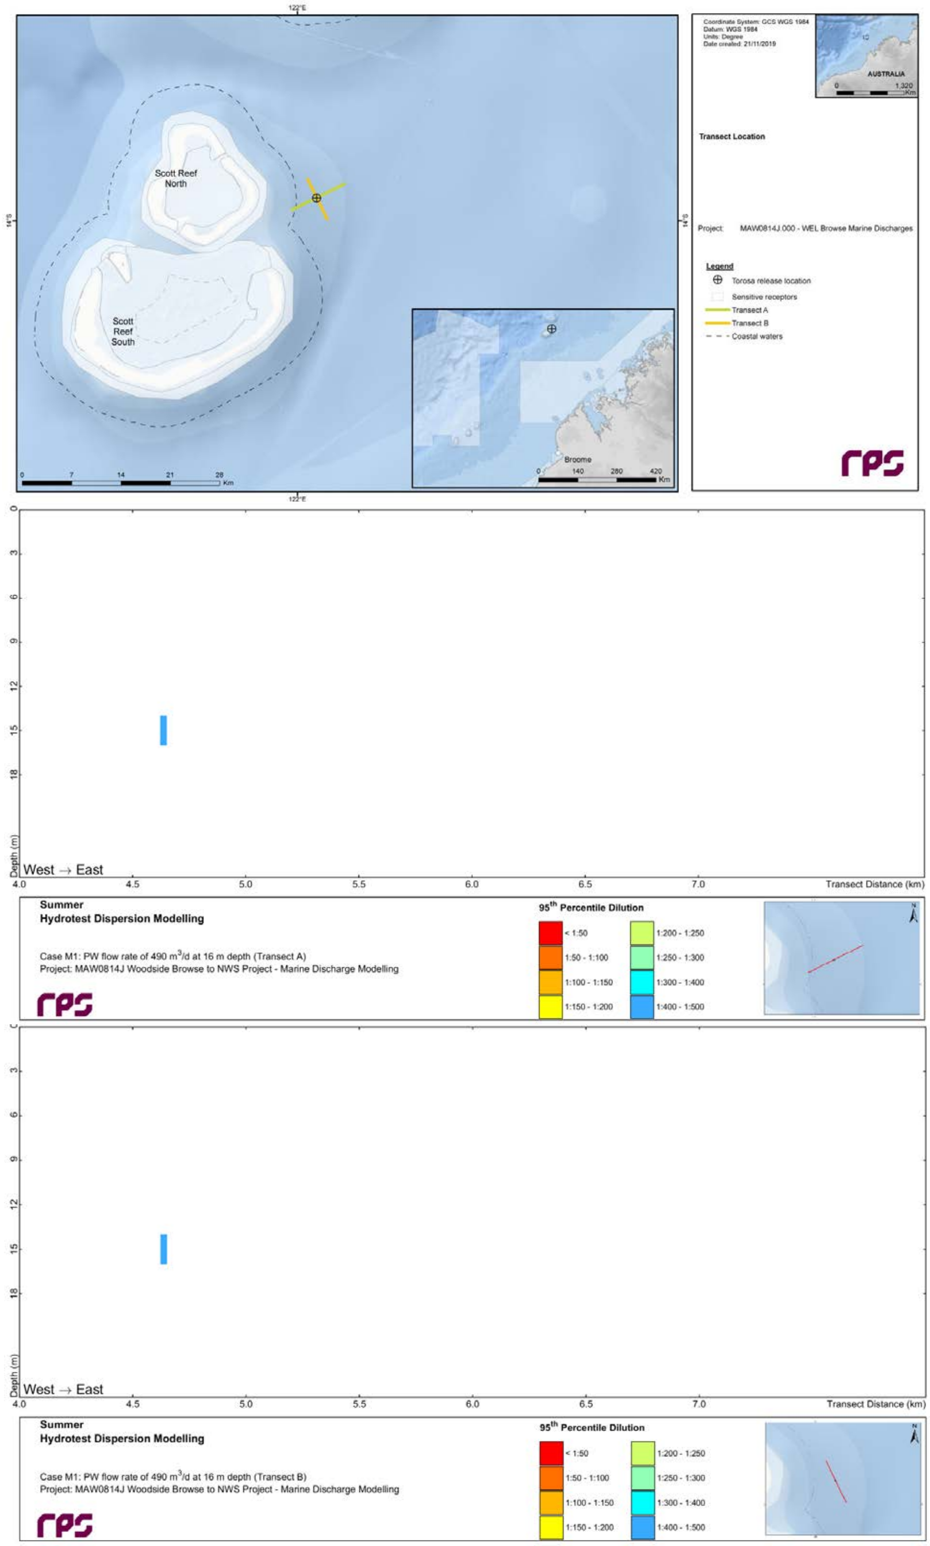

Figure 3.51 Vertical cross-section plots of predicted minimum dilutions at the 95th percentile under summer conditions for Case M (14 m depth discharge at 490 m^3/d flow rate). Transect locations are shown in the top panel, with transect A shown in the middle panel and transect B shown in the bottom panel. Spatial representation of this data is shown in Figure 3.48.

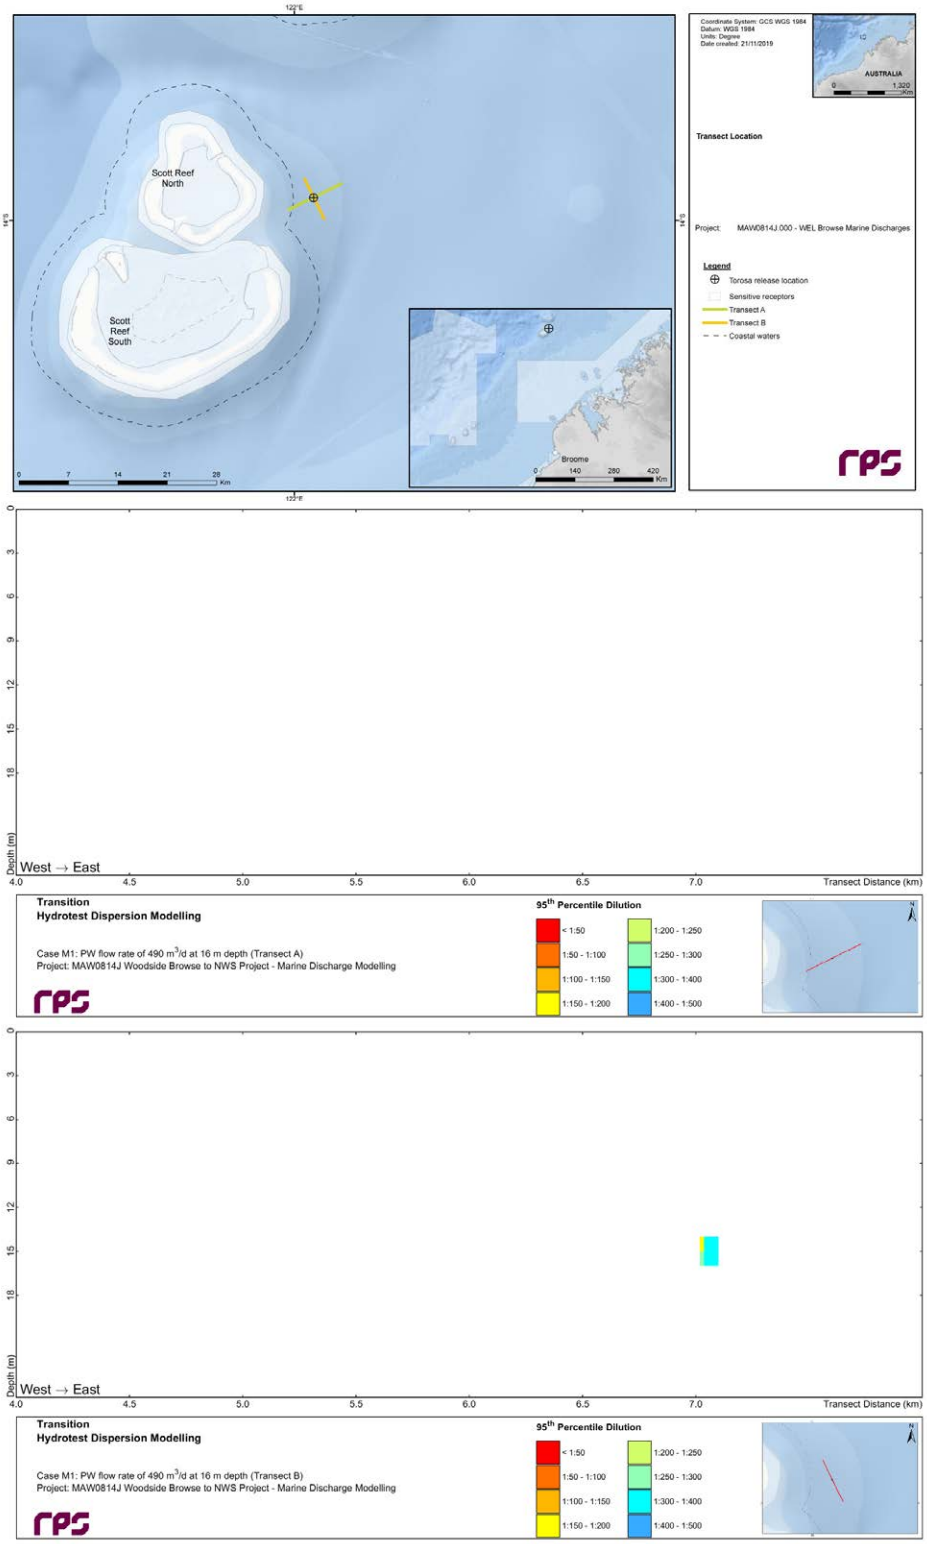

Figure 3.52 Vertical cross-section plots of predicted minimum dilutions at the 95th percentile under transitional conditions for Case M (14 m depth discharge at 490 m^3/d flow rate). Transect locations are shown in the top panel, with transect A shown in the middle panel and transect B shown in the bottom panel. Spatial representation of this data is shown in Figure 3.49.

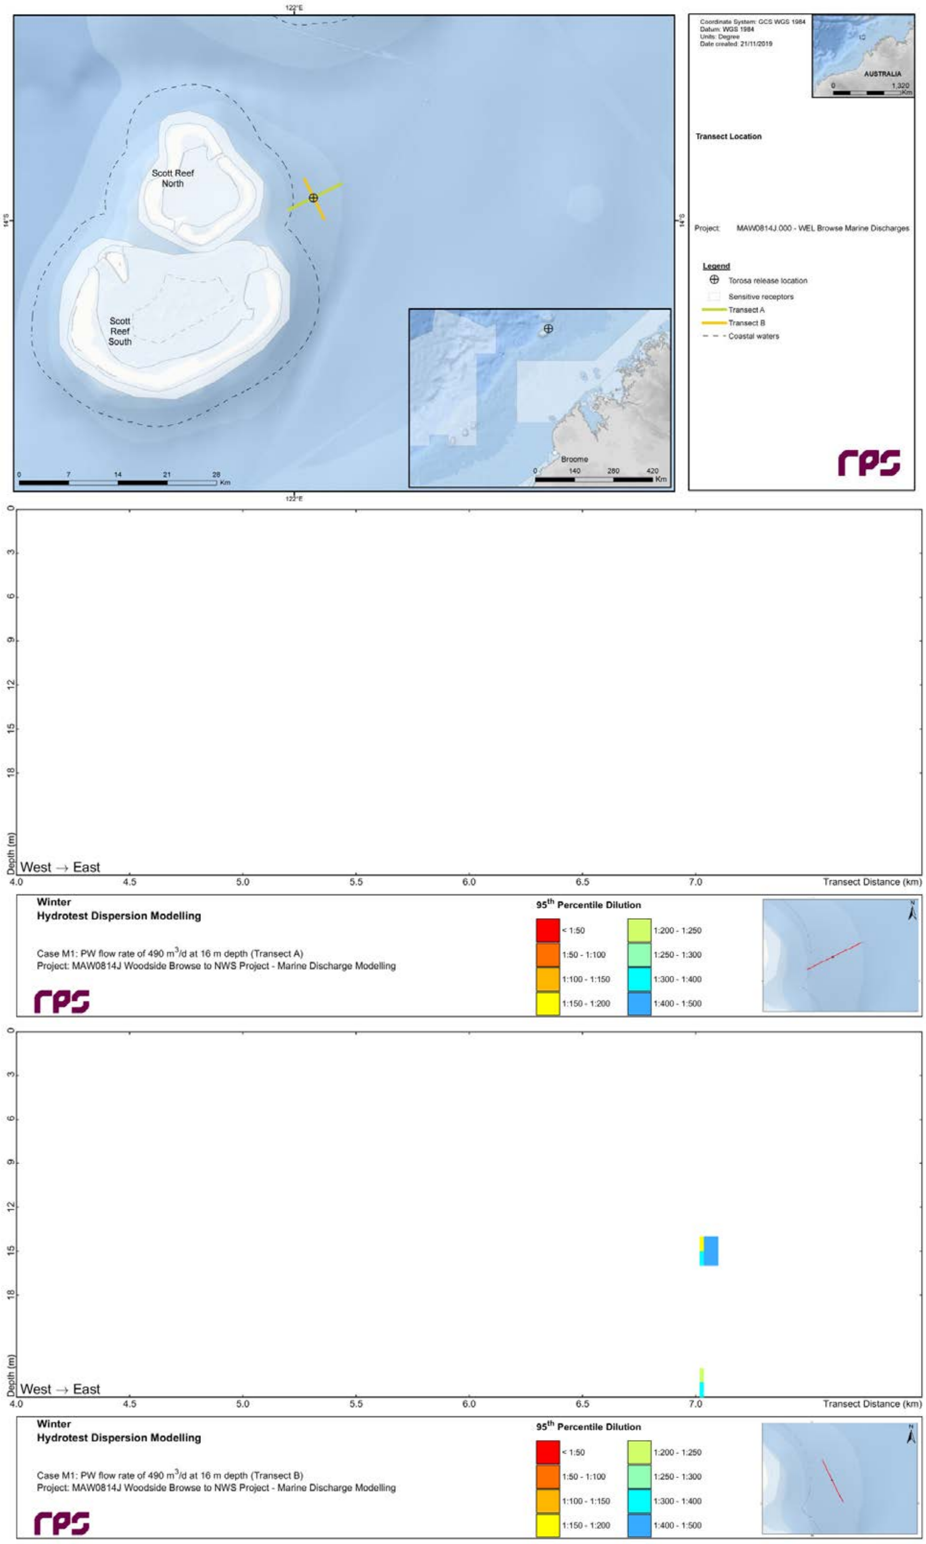

Figure 3.53 Vertical cross-section plots of predicted minimum dilutions at the 95th percentile under winter conditions for Case M (14 m depth discharge at 490 m^3/d flow rate). Transect locations are shown in the top panel, with transect A shown in the middle panel and transect B shown in the bottom panel. Spatial representation of this data is shown in Figure 3.50.

3.2.4.3 Annualised Analysis

3.2.4.3.1 Summary

The model outputs for each season (summer, transitional and winter) over the ten-year hindcast period (2006-2015) were combined and analysed on an annualised basis.

Table 3.53 and Table 3.56 summarise, for Cases P and M respectively, the average and minimum dilution achieved at specific radial distances from the discharge location – as well as at or within the Scott Reef area defined by the 3 nm State water boundary – for each percentile over the annual period.

The minimum levels of dilution achieved at or within the Scott Reef receptor at the 95th percentile in any season are predicted to be 1:1,507 for Case P and 1:17,674 for Case M.

Table 3.54 provides for Case P a summary of the annualised maximum distances from the discharge location to achieve an example dilution level of 1:300 for each percentile. The results indicate that the release of effluent under all seasonal conditions results in rapid dispersion within the ambient environment. Dilution to reach the 1:300 level at the 95th percentile – this being the maximum spatial extent of the relevant dilution contour from the discharge location in any season – is achieved within a maximum area of influence of 0.9 km.

Table 3.55 provides for Case P a summary of the annualised total areas of coverage for the 1:300 dilution contour for each percentile. The area of exposure defined by the relevant dilution contour is predicted to reach a maximum value of 0.7 km^2 at the 95th percentile across all seasons.

For Cases P and M, the aggregated spatial extents of the minimum dilutions at the 95th percentile are presented in Figure 3.54 and Figure 3.55, respectively. Note that the contours represent the lowest predicted dilution (highest concentration) at any given time step through the water column and do not consider frequency or duration.

The results presented assume that no processes other than dilution would reduce the source concentrations over time, and therefore can be considered as conservative outcomes.

3.2.4.3.2 Discharge Case P: Flow Rate of 5,723 m³/day at 14 m Depth

Table 3.53 Annualised average and minimum dilutions (1:x) achieved at specific radial distances from the PW discharge location for Case P (14 m depth discharge at 5,723 m³/d flow rate).

3.2.5 Hydrotest Discharges

3.2.5.1 General Observations

Figure 3.56 shows example time series snapshots of predicted dilutions during a single simulation at 4-hour intervals from 00:00 to 20:00 on 12th January 2010. This simulation – selected merely to be representative of typical conditions – considers the Case H1 discharge of 736,000 m^3 at 117 m BMSL at the PLET near the NRC. The spatially-varying orientation of the plume with the currents and the rapidly-varying nature of the concentrations around the source can be observed. The snapshots also show the combined effect of the tide and the drift currents, with a clear tidal oscillation.

These snapshots illustrate that the dilutions (and in turn concentrations) become more variable over time because of changes in current speed and direction. Higher dilutions (lower concentrations) are predicted during periods of increased current speed, whereas patches of lower dilutions (higher concentrations) tend to accumulate during the turning of the tide or during periods of weak drift currents. During prolonged periods of lowered current speed, the plume has a more continuous appearance, with higher-concentration patches moving as a unified group.

The snapshots in Figure 3.56 show a contiguous plume emanating from the source. Within this plume, higher-concentration patches – attributable to periodic tide reversals which cause the existing plume to repeatedly pass over the source – are most evident closer to the source, while towards the outermost extents a highly-diluted sub-plume has begun to detach from the main plume.

These findings agree with the research of King & McAllister (1997, 1998) who noted that concentrations within effluent plumes generated by an offshore platform were patchy and likely to peak around the reversal of the tides.

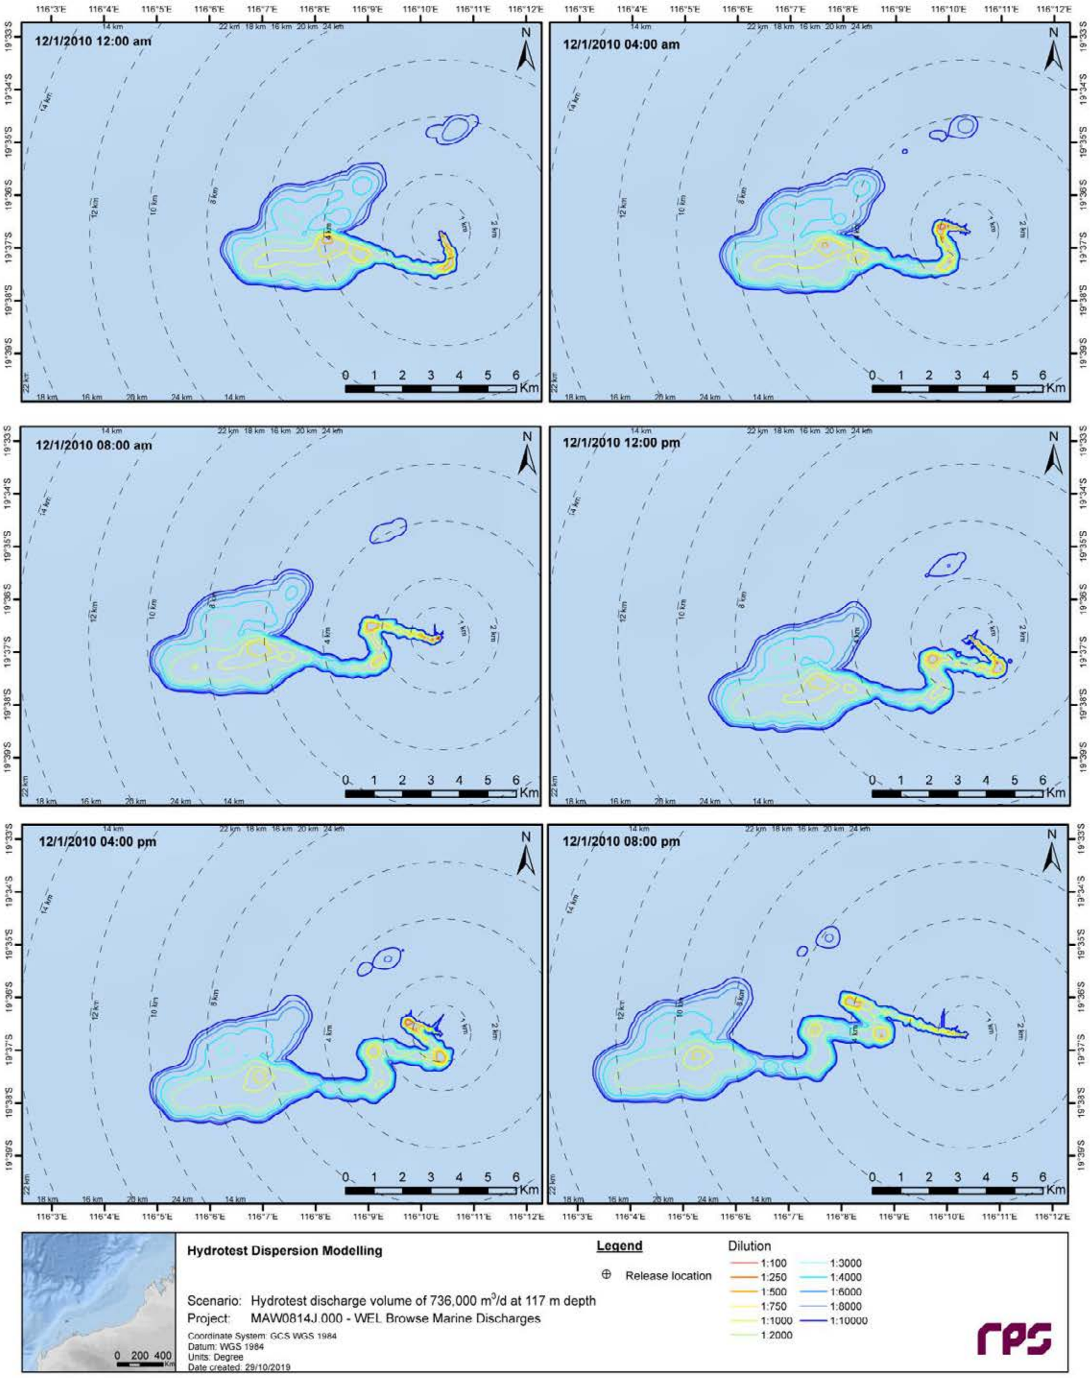

Figure 3.56 Snapshots of predicted dilution levels, at 4-hour intervals from 00:00 to 20:00 on 12th January 2010, for Case H1 (NRC tie-in PLET 736,000 m^3 hydrotest discharge).

3.2.5.2 Seasonal Analysis

3.2.5.2.1 Summary

The model outputs over the ten-year hindcast period (2006-2015) were combined and analysed on a seasonal basis (summer, transitional and winter). This approach assists with identifying the potential exposure to surrounding sensitive receptors whilst considering inter-annual variability in ocean current conditions.

Table 3.57, Table 3.61, Table 3.65 and Table 3.69 summarise, for Cases H1, H2, H3a and H3b respectively, the average and minimum dilution achieved at specific radial distances from the discharge location – as well as at or within the boundary of the nearest sensitive receptor – for each season and percentile, with the application of a rolling 48-hour median to the data. The discharge location for Case H1 is distant from Scott Reef and the nearest receptor is Rankin Bank, while for Cases H2, H3a and H3b the nearest receptor is Scott Reef (defined by the 3 nm State water boundary).

Table 3.58, Table 3.62, Table 3.66 and Table 3.70 provide, for Cases H1, H2, H3a and H3b respectively, summaries of the maximum distances from the discharge location to achieve an example dilution level of 1:10,000 for each season and percentile. The results indicate that the release of effluent under all seasonal conditions results in slow dispersion within the ambient environment. For Case H1, a 1:10,000 dilution is achieved within an area of influence ranging from 9.0-16.1 km at the 95th percentile (Table 3.58), with the predominant plume travel direction being south-westerly throughout the year (Figure 3.57 to Figure 3.59). For Case H2, the maximum spatial extent of the relevant dilution contour varies from 8.0-12.5 km at the 95th percentile (Table 3.62), with the predominant axis of plume movement being north-northwest/south-southeast throughout the year (Figure 3.63 to Figure 3.65). For Case H3a, the maximum spatial extent of the relevant dilution contour is in the range 15.5-23.4 km at the 95th percentile (Table 3.66), with plumes travelling mostly to the north-east during transitional months, the south-west during winter, and both the north-east and south-west during summer (Figure 3.69 to Figure 3.71). For Case H3b, dilution to reach the 1:10,000 level is achieved within a distance of 7.3-8.2 km at the 95th percentile (Table 3.70), with plumes moving along a north-northwest/south-southeast axis throughout the year (Figure 3.75 to Figure 3.77).

Table 3.59, Table 3.63, Table 3.67 and Table 3.71 provide, for Cases H1, H2, H3a and H3b respectively, summaries of the total areas of coverage for the 1:10,000 dilution contour for each season and percentile. For Case H1, the area of exposure defined by the relevant dilution contour is predicted to reach a maximum value of 36.2-44.3 km^2 at the 95th percentile (Table 3.59). For Case H2, the corresponding maximum area of exposure is 30.7-74.6 km^2 at the 95th percentile (Table 3.63). For Case H3a, the maximum area of exposure is predicted to be 38.3-57.3 km^2 at the 95th percentile (Table 3.67). For Case H3b, the maximum area of exposure is forecast as 18.2-22.2 km^2 at the 95th percentile (Table 3.71).

Table 3.60, Table 3.64, Table 3.68 and Table 3.72 provide, for Cases H1, H2, H3a and H3b respectively, summaries of the maximum depths from the discharge location to achieve 1:10,000 dilution for each season and percentile. Given the near-seabed depths of each discharge and the near neutrally buoyant nature of the plumes, maximum depths are predicted as equivalent to the seabed depth in each case.

For Cases H1, H2, H3a and H3b, the aggregated spatial extents of the minimum dilutions for each season at the 95th percentile are presented in Figure 3.57 to Figure 3.59, Figure 3.63 to Figure 3.65, Figure 3.69 to Figure 3.71 and Figure 3.75 to Figure 3.77, respectively. Note that the contours represent the lowest predicted dilution (highest concentration) at any given time step through the water column and do not consider frequency or duration.

The results presented assume that no processes other than dilution would reduce the source concentrations over time, and therefore can be considered as conservative outcomes.

Seasonal water column cross-section figures of 95th percentile dilution, extracted along perpendicular transects running through the origin points of the discharge (one of which is broadly aligned with the principal travel direction of the plume at each location), are presented in Figure 3.60 to Figure 3.62 (Case H1), Figure 3.66 to Figure 3.68 (Case H2), Figure 3.72 to Figure 3.74 (Case H3a) and Figure 3.78 to Figure 3.80 (Case H3b). In each case, the neutrally buoyant plumes are predicted to remain relatively close to the seabed as they disperse. It is evident that the plumes will be heavily influenced by local bathymetry features and may travel up slopes if currents in the lower water column are conducive to this effect. For the Case H1 discharge, the plume centreline will remain at a depth of more than 100 m below the water surface. For Cases H2, H3a and H3b, the plume centrelines will remain at depths of more than 450 m.

It should be noted that the bathymetry slopes shown in the water column cross-section figures are exaggerated due to the spatial scales used; the vertical axis is presented in units of metres, while the horizontal axis is presented in units of kilometres.

3.2.5.2.2 Discharge Case H1: NRC Tie-In PLET Hydrotest Discharge of 736,000 m^3 at 117 m Depth

Table 3.57 Average and minimum dilutions (1:x) achieved at specific radial distances from the hydrotest discharge location in each season for Case H1 (NRC tie-in PLET 736,000 m^3 hydrotest discharge), with application of a rolling 48-hour median to the dilution data.

† This receptor is outside the model domain and predictions of dilution are unavailable at or within its boundaries. Given the high levels of dilution predicted within the extent of the model domain (20 km) in the direction of Rankin Bank, and the remaining distance (~40 km) from the edge of the model domain to the receptor, it can be assumed that a minimum dilution level of >>20,000 will occur at or within the receptor boundaries at all percentiles.

Table 3.58 Maximum distance from the hydrotest discharge location to achieve 1:10,000 dilution in each season for Case H1 (NRC tie-in PLET 736,000 m^3 hydrotest discharge), with application of a rolling 48-hour median to the dilution data.

Percentile	Season	Maximum distance (m) from discharge location to achieve given dilution
95th	Summer	16,137
	Transitional	9,829
	Winter	8,965
99th	Summer	22,551
	Transitional	15,322
	Winter	16,158
100th	Summer	22,925
	Transitional	16,685
	Winter	17,989

Table 3.59 Total area of coverage for 1:10,000 dilution in each season for Case H1 (NRC tie-in PLET 736,000 m^3 hydrotest discharge), with application of a rolling 48-hour median to the dilution data.

Percentile	Season	Total area (km^2) of coverage for given dilution
95th	Summer	44.30
	Transitional	40.70
	Winter	36.20
99th	Summer	150.90
	Transitional	107.30
	Winter	90.50
100th	Summer	182.70
	Transitional	141.00
	Winter	109.80

Table 3.60 Maximum depth from the hydrotest discharge location to achieve 1:10,000 dilution in each season for Case H1 (NRC tie-in PLET 736,000 m^3 hydrotest discharge).

Season	Maximum depth (m) from sea surface to achieve given dilution
Summer	117 (seabed)
Transitional	117 (seabed)
Winter	117 (seabed)

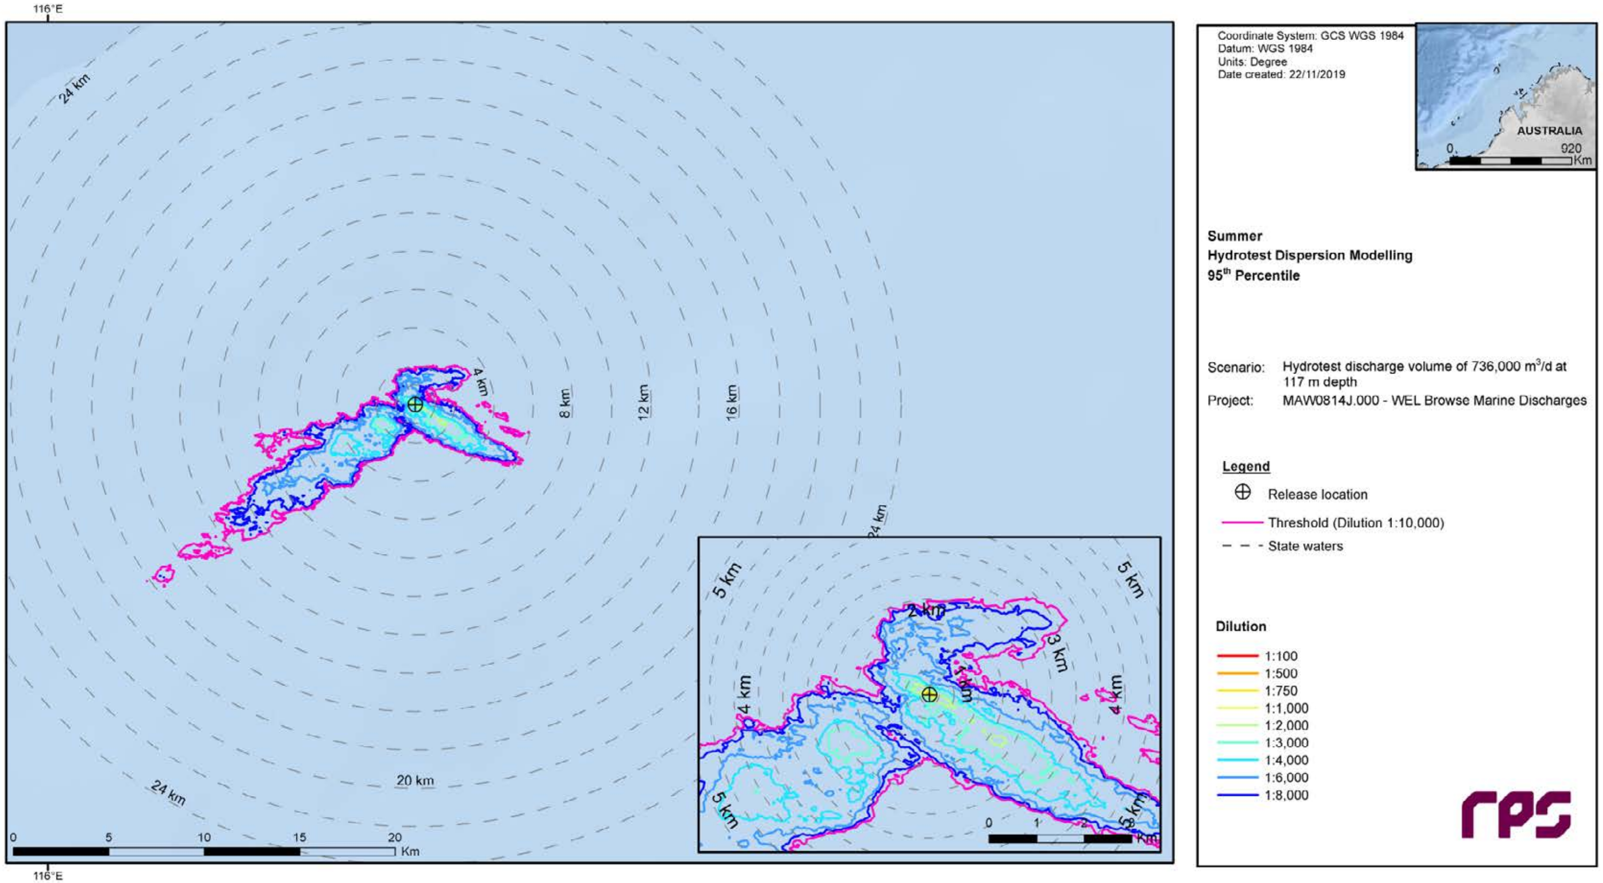

Figure 3.57 Predicted minimum dilutions at the 95th percentile under summer conditions for Case H1 (NRC tie-in PLET 736,000 m^3 hydrotest discharge), with a rolling 48-hour median of the dilution data.

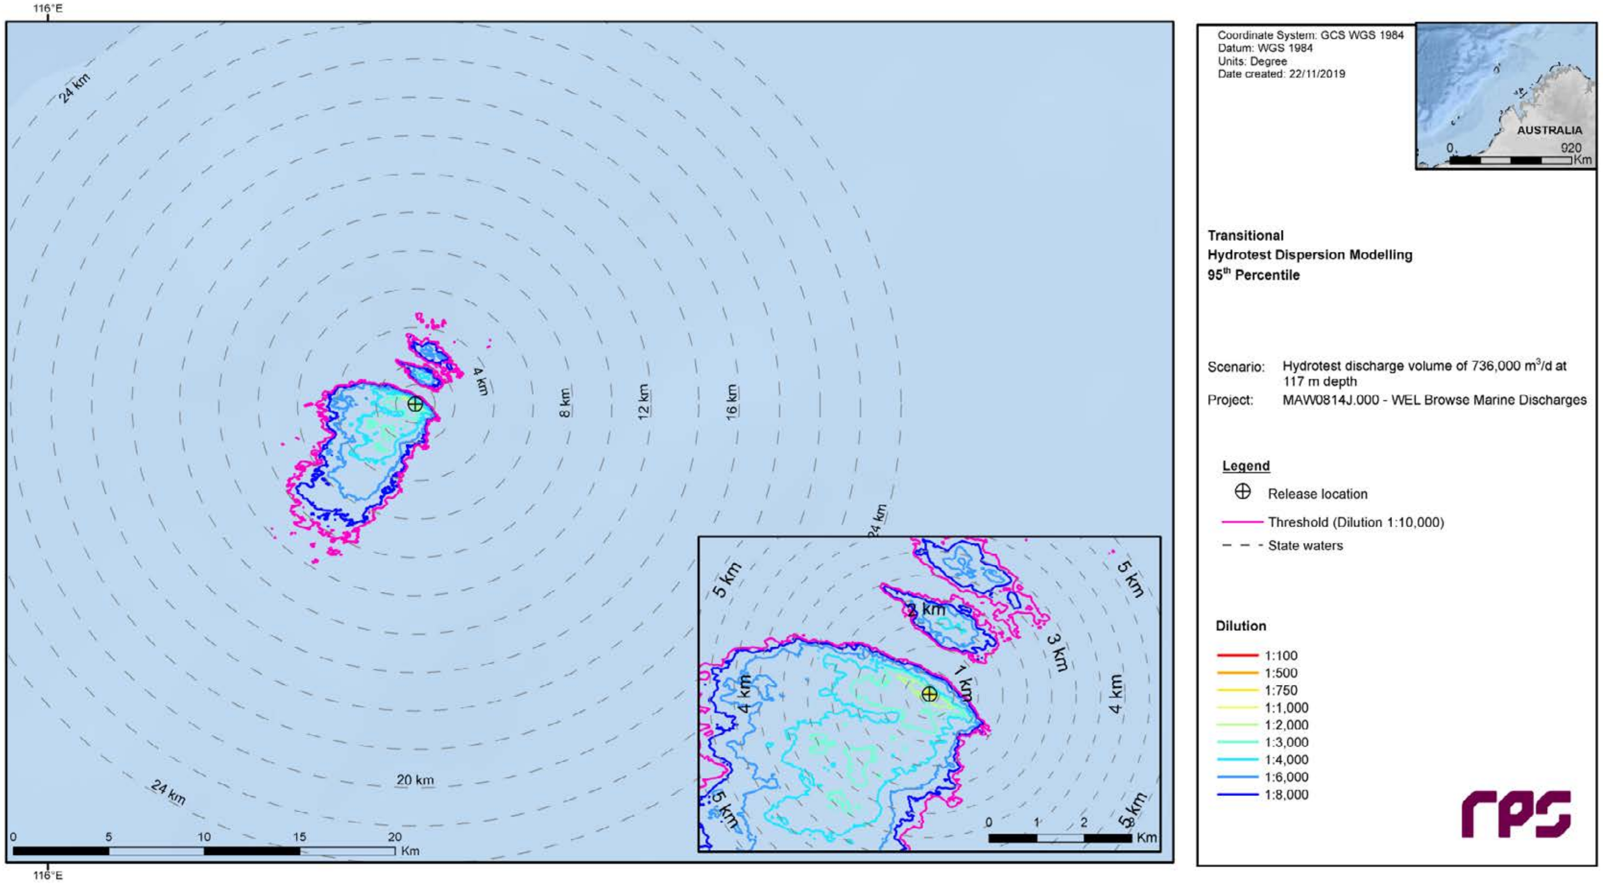

Figure 3.58 Predicted minimum dilutions at the 95th percentile under transitional conditions for Case H1 (NRC tie-in PLET 736,000 m^3 hydrotest discharge), with a rolling 48-hour median of the dilution data.

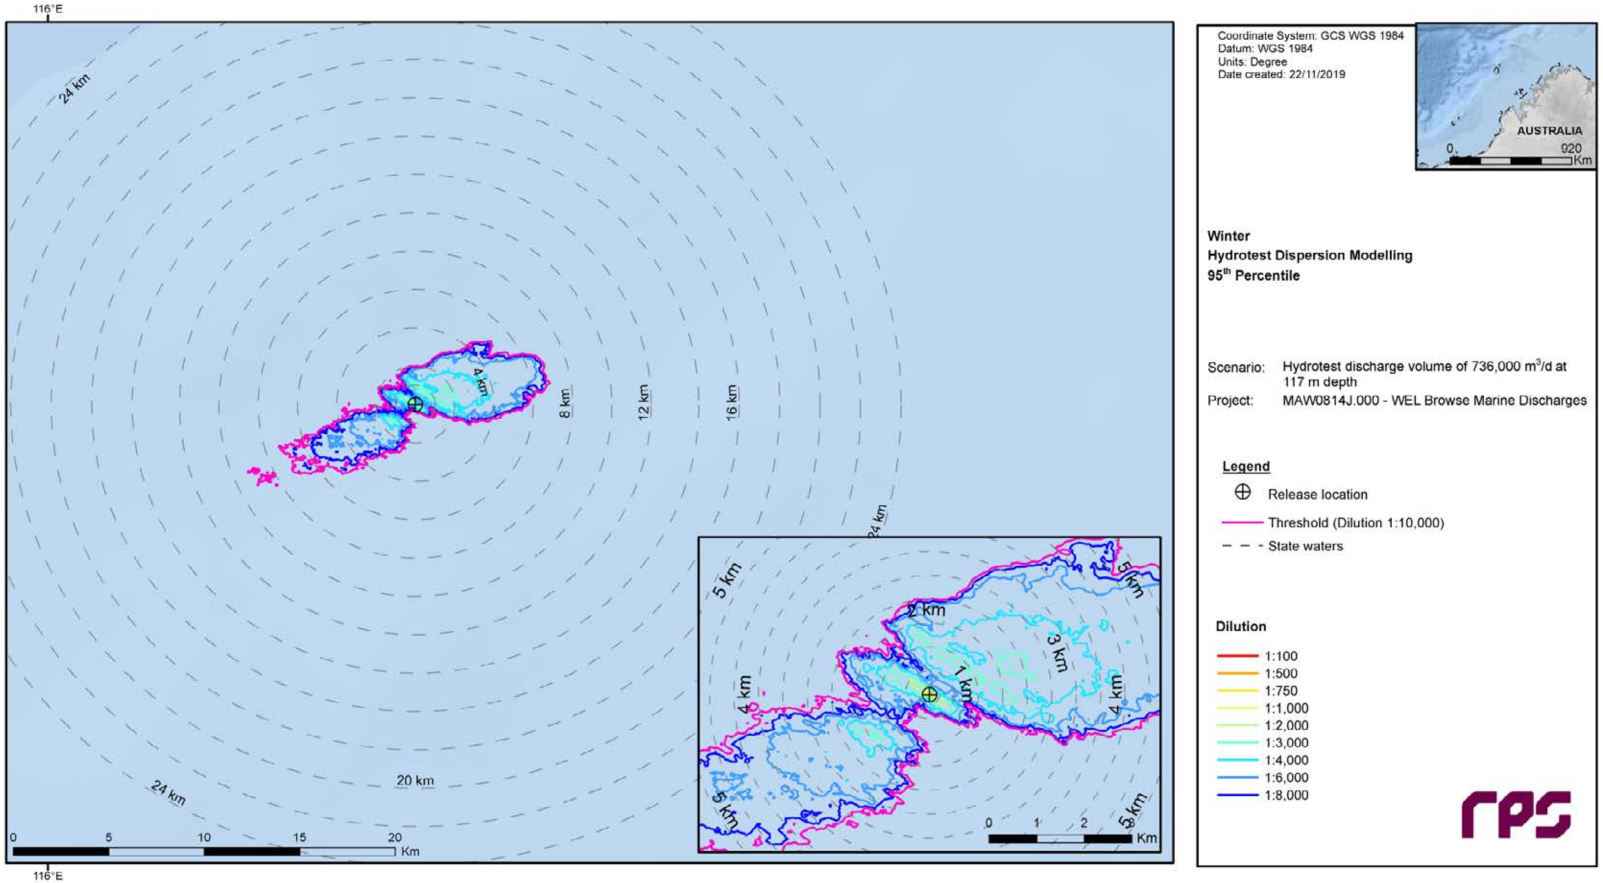

Figure 3.59 Predicted minimum dilutions at the 95th percentile under winter conditions for Case H1 (NRC tie-in PLET 736,000 m^3 hydrotest discharge), with a rolling 48-hour median of the dilution data.

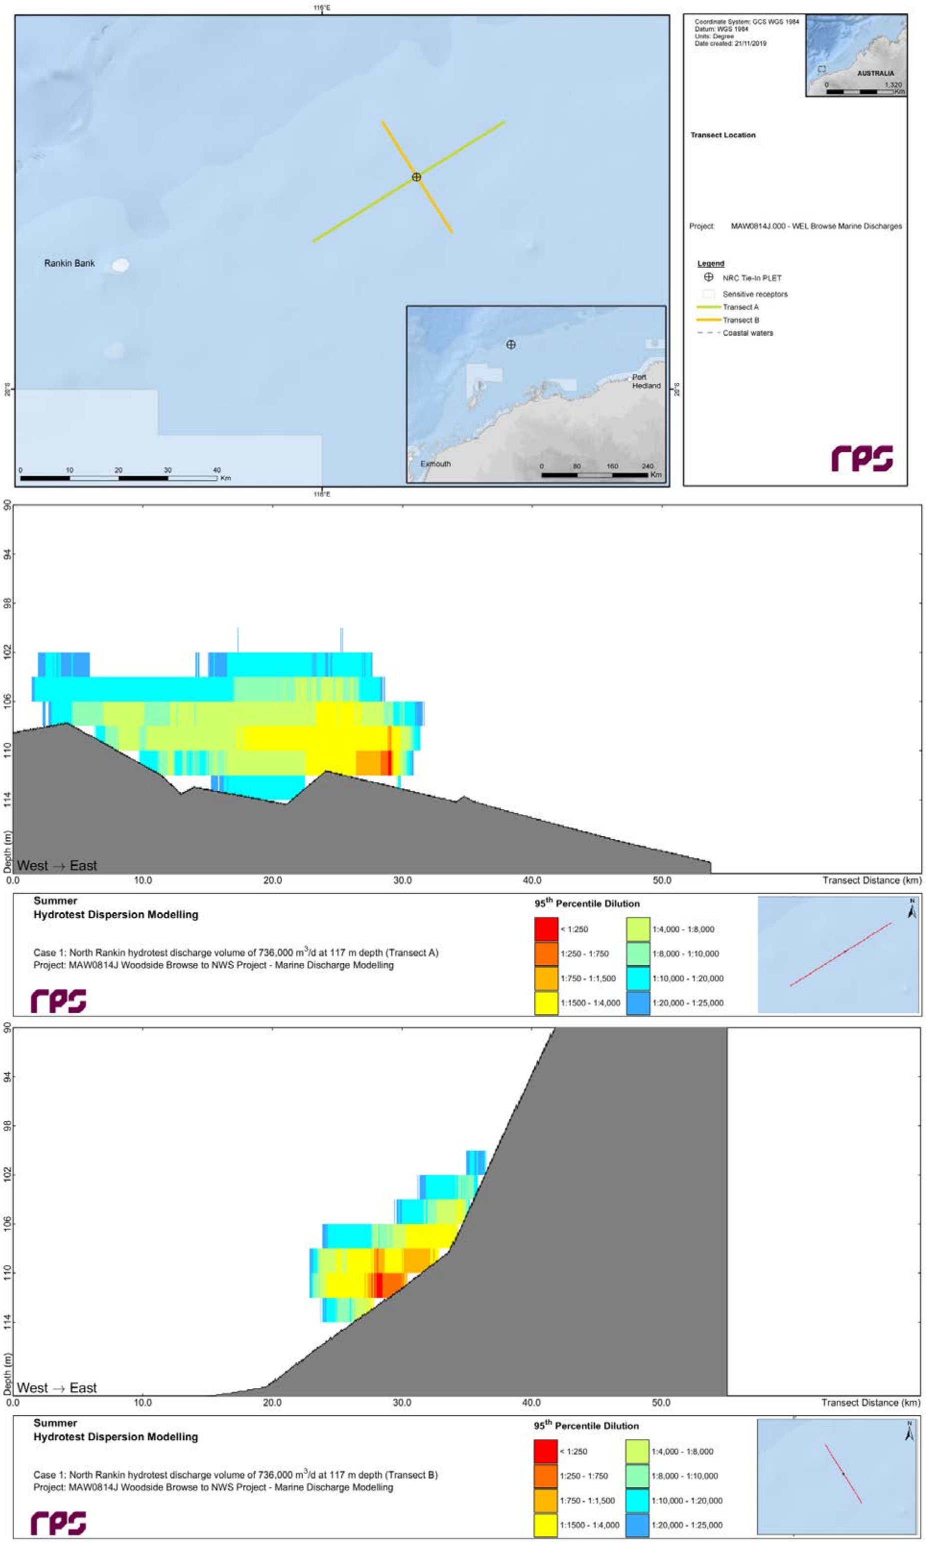

Figure 3.60 Vertical cross-section plots of predicted minimum dilutions at the 95th percentile under summer conditions for Case H1 (NRC tie-in PLET 736,000 m^3 hydrotest discharge). Transect locations are shown in the top panel, with transect A shown in the middle panel and transect B shown in the bottom panel. Spatial representation of this data is shown in Figure 3.57.

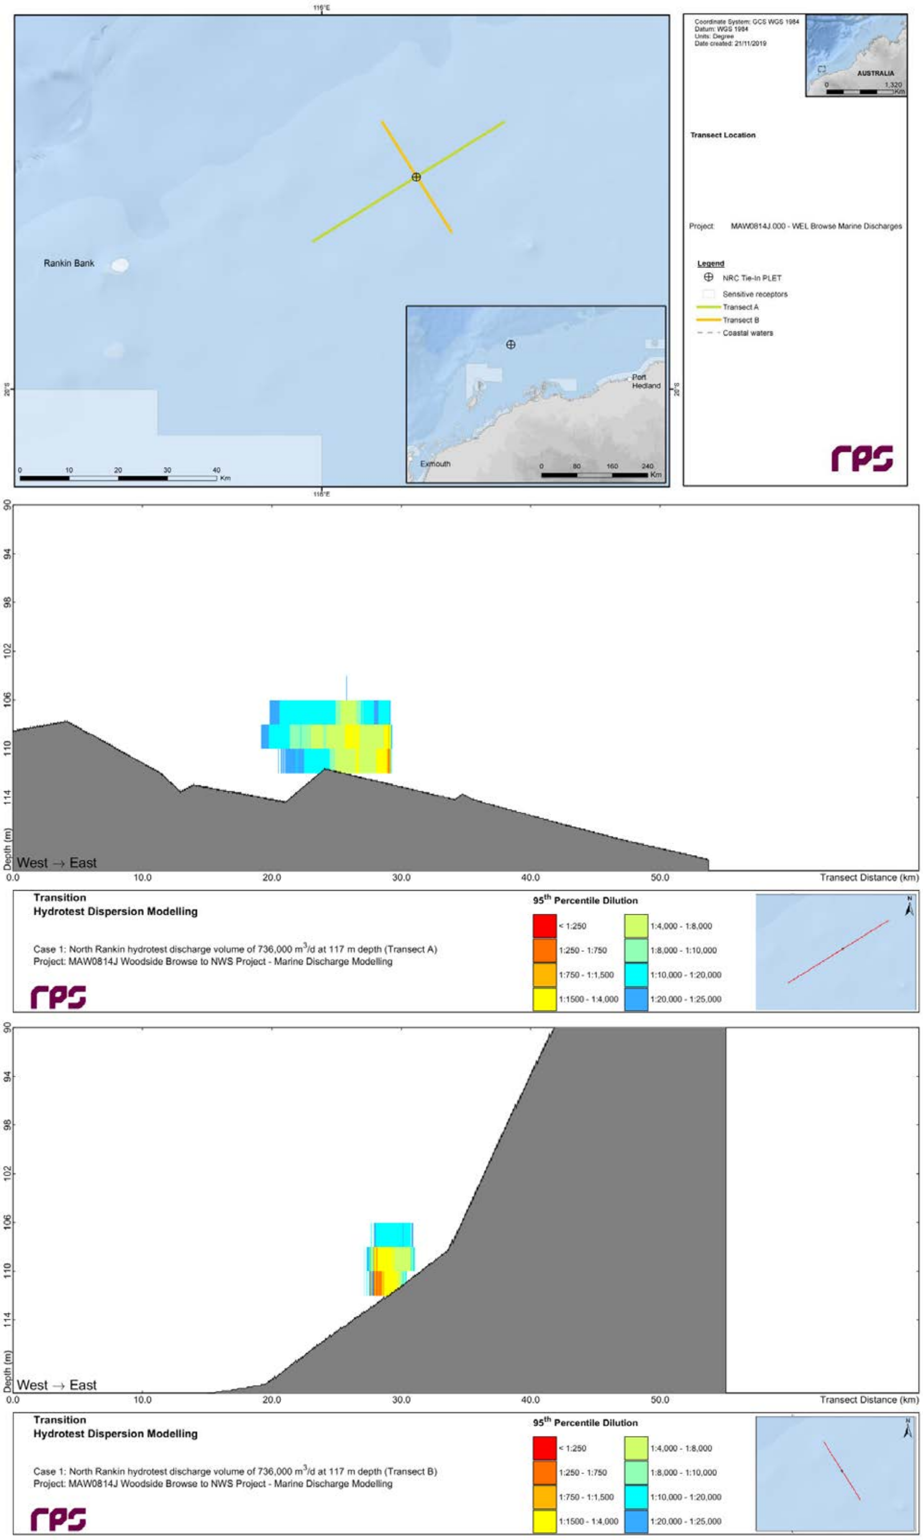

Figure 3.61 Vertical cross-section plots of predicted minimum dilutions at the 95th percentile under transitional conditions for Case H1 (NRC tie-in PLET 736,000 m^3 hydrotest discharge). Transect locations are shown in the top panel, with transect A shown in the middle panel and transect B shown in the bottom panel. Spatial representation of this data is shown in Figure 3.58.

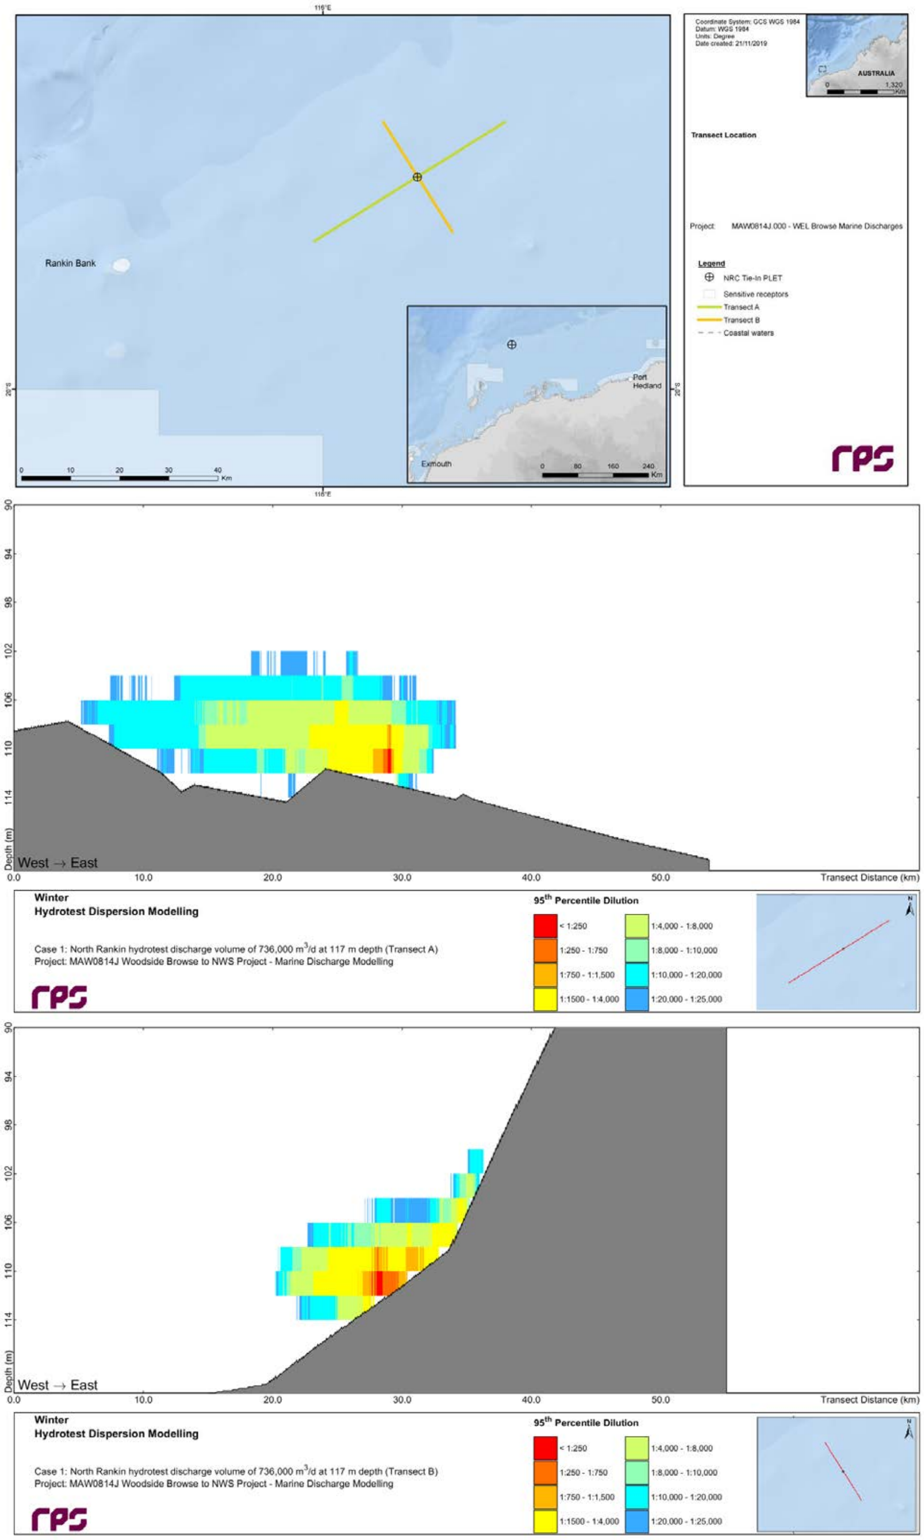

Figure 3.62 Vertical cross-section plots of predicted minimum dilutions at the 95th percentile under winter conditions for Case H1 (NRC tie-in PLET 736,000 m³ hydrotest discharge). Transect locations are shown in the top panel, with transect A shown in the middle panel and transect B shown in the bottom panel. Spatial representation of this data is shown in Figure 3.59.

3.2.5.2.3 Discharge Case H2: Torosa PLET Hydrotest Discharge of 846,000 m^3 at 461 m Depth

Table 3.61 Average and minimum dilutions (1:x) achieved at specific radial distances from the hydrotest discharge location in each season for Case H2 (Torosa PLET 846,000 m^3 hydrotest discharge), with application of a rolling 48-hour median to the dilution data.

† This receptor is outside the model domain and predictions of dilution are unavailable at or within its boundaries. Given the high levels of dilution predicted within the extent of the model domain (20 km) in the direction of Scott Reef, and the remaining distance (~12 km) from the edge of the model domain to the receptor, it can be assumed that a minimum dilution level of >20,000 will occur at or within the receptor boundaries at all percentiles.

Table 3.66 Maximum distance from the hydrotest discharge location to achieve 1:10,000 dilution in each season for Case H3a (Brecknock/Calliance PLET 790,000 m^3 hydrotest discharge), with application of a rolling 48-hour median to the dilution data.

Percentile	Season	Maximum distance (m) from discharge location to achieve given dilution
95th	Summer	23,421
	Transitional	15,474
	Winter	18,032
99th	Summer	26,400
	Transitional	22,836
	Winter	24,340
100th	Summer	26,502
	Transitional	22,923
	Winter	24,556

Table 3.67 Total area of coverage for 1:10,000 dilution in each season for Case H3a (Brecknock/Calliance PLET 790,000 m^3 hydrotest discharge), with application of a rolling 48-hour median to the dilution data.

Percentile	Season	Total area (km^2) of coverage for given dilution
95th	Summer	57.30
	Transitional	42.20
	Winter	38.30
99th	Summer	160.80
	Transitional	172.00
	Winter	175.80
100th	Summer	189.00
	Transitional	222.50
	Winter	213.60

Table 3.68 Maximum depth from the hydrotest discharge location to achieve 1:10,000 dilution in each season for Case H3a (Brecknock/Calliance PLET 790,000 m^3 hydrotest discharge).

Season	Maximum depth (m) from sea surface to achieve given dilution
Summer	539 (seabed)
Transitional	539 (seabed)
Winter	539 (seabed)

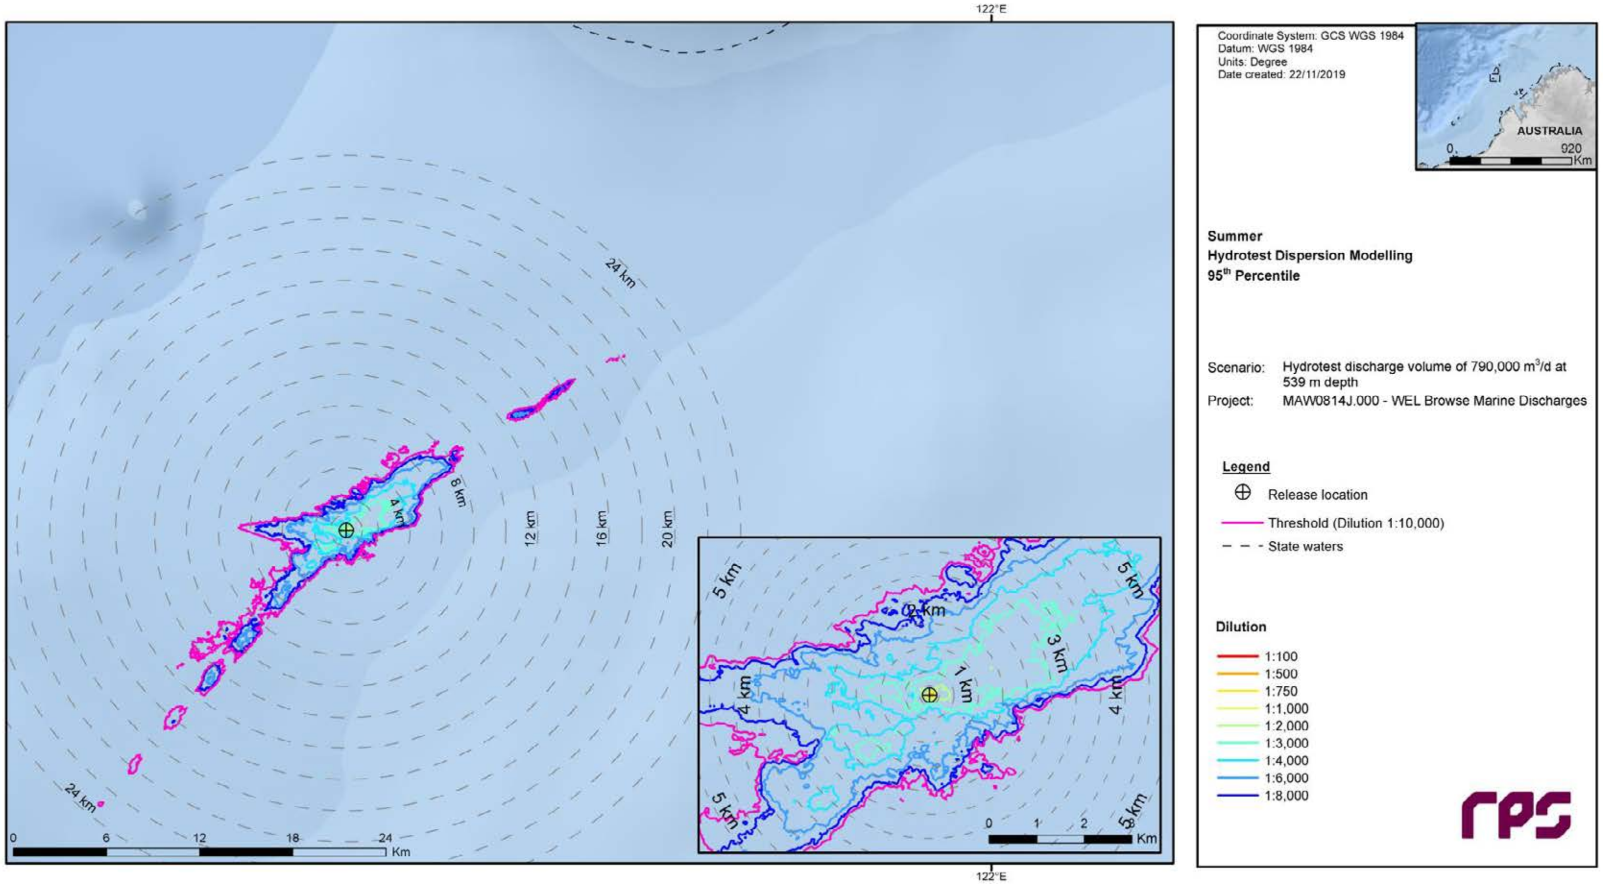

Figure 3.69 Predicted minimum dilutions at the 95th percentile under summer conditions for Case H3a (Brecknock/Calliance PLET 790,000 m^3 hydrotest discharge), with a rolling 48-hour median of the dilution data.

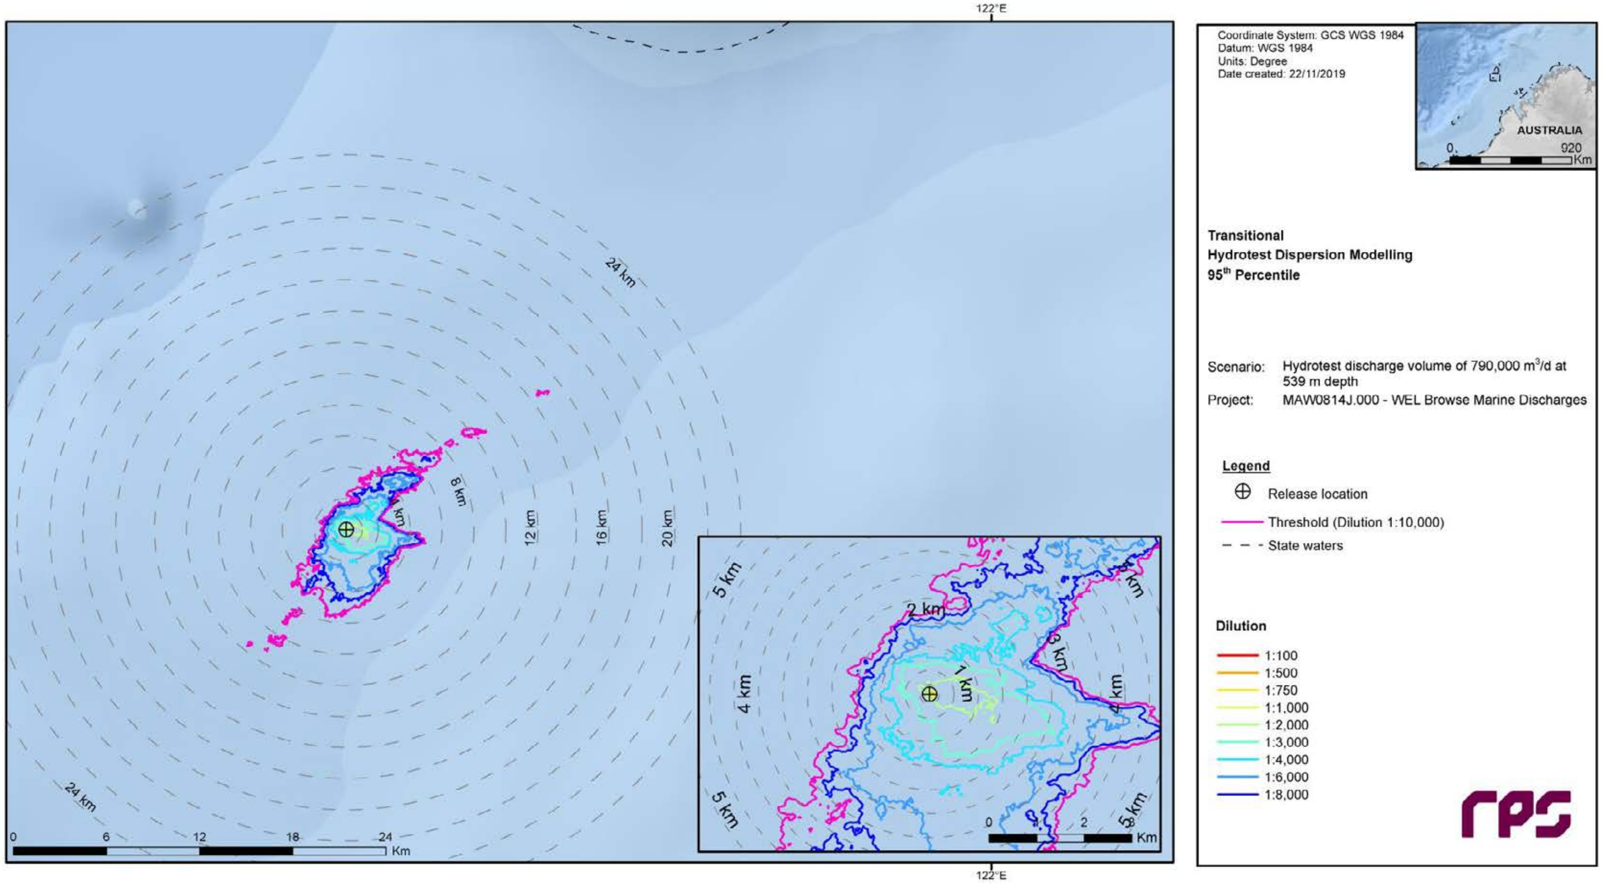

Figure 3.70 Predicted minimum dilutions at the 95th percentile under transitional conditions for Case H3a (Brecknock/Calliance PLET 790,000 m^3 hydrotest discharge), with a rolling 48-hour median of the dilution data.

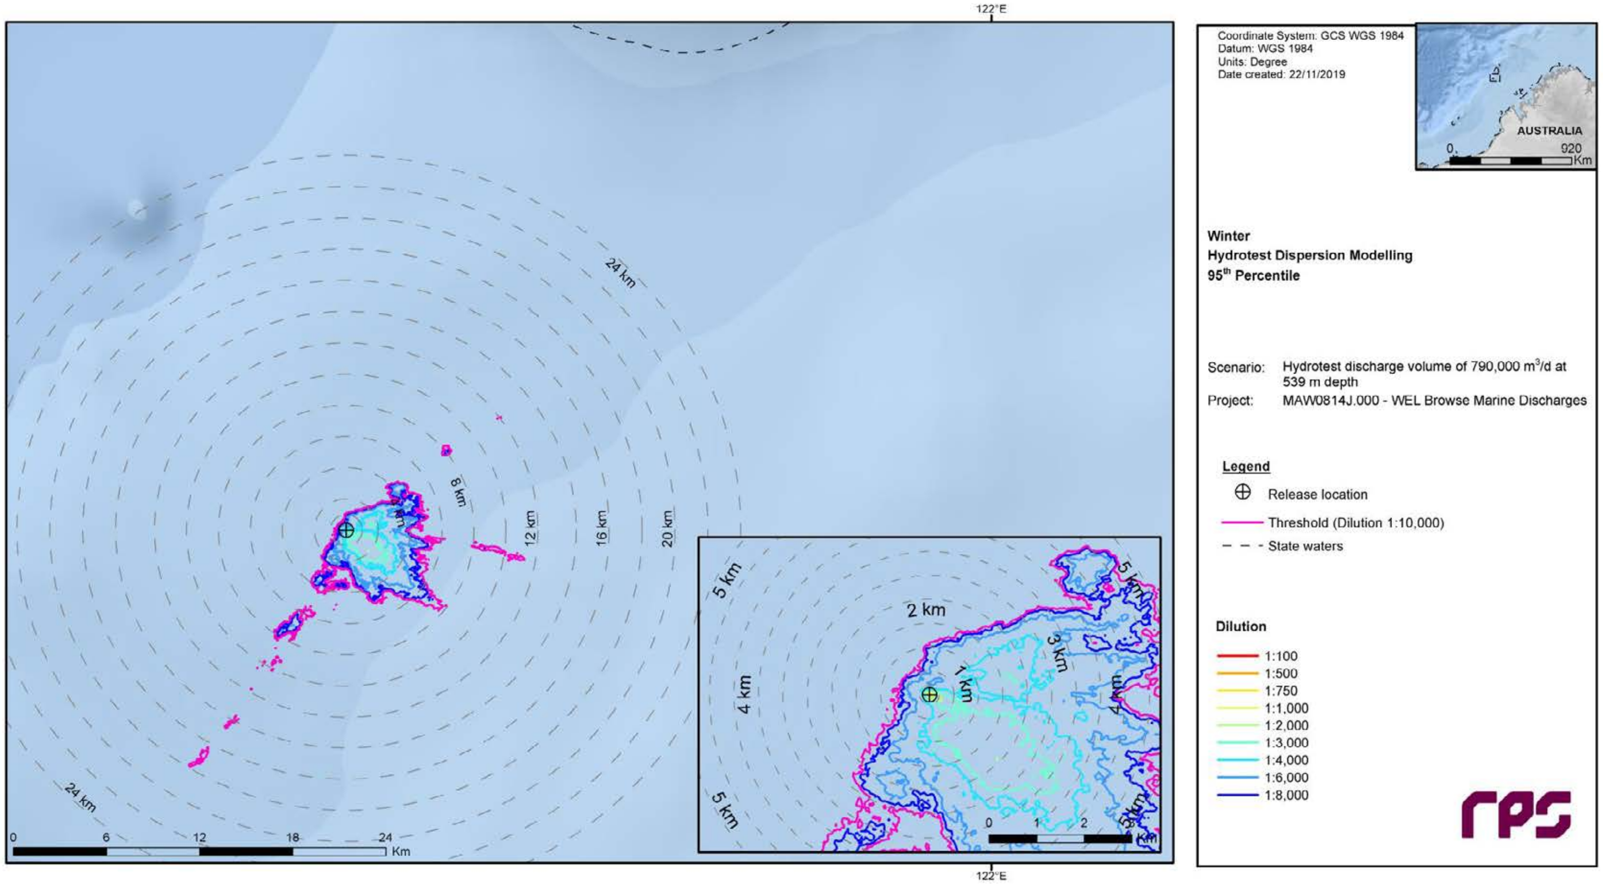

Figure 3.71 Predicted minimum dilutions at the 95th percentile under winter conditions for Case H3a (Brecknock/Calliance PLET 790,000 m^3 hydrotest discharge), with a rolling 48-hour median of the dilution data.

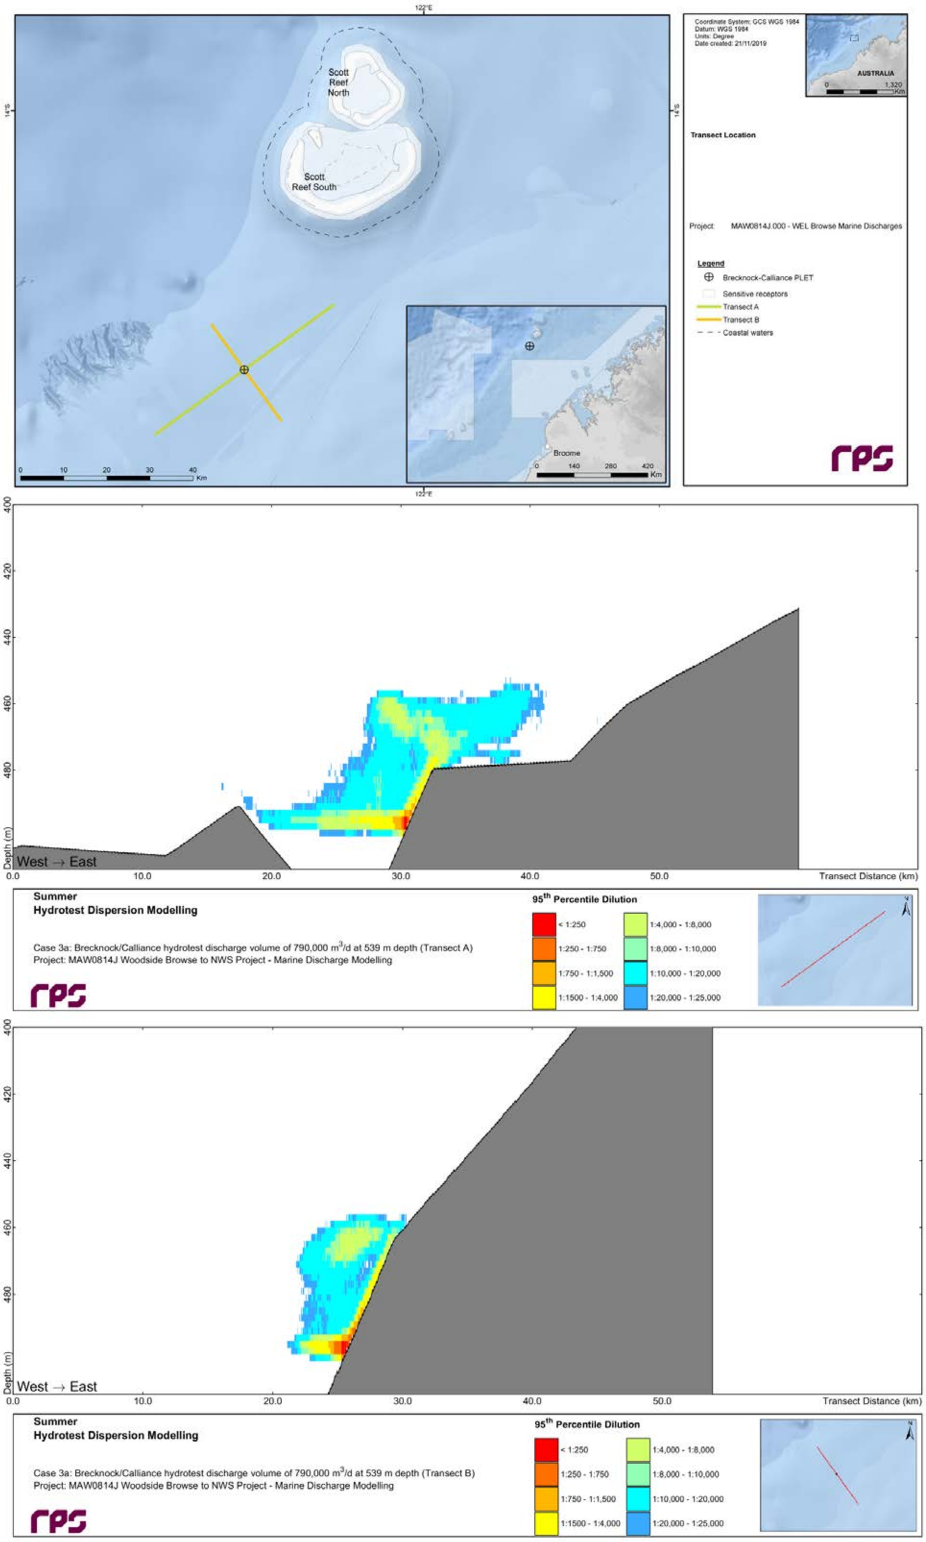

Figure 3.72 Vertical cross-section plots of predicted minimum dilutions at the 95th percentile under summer conditions for Case H3a (Brecknock/Calliance PLET 790,000 m^3 hydrotest discharge). Transect locations are shown in the top panel, with transect A shown in the middle panel and transect B shown in the bottom panel. Spatial representation of this data is shown in Figure 3.69.

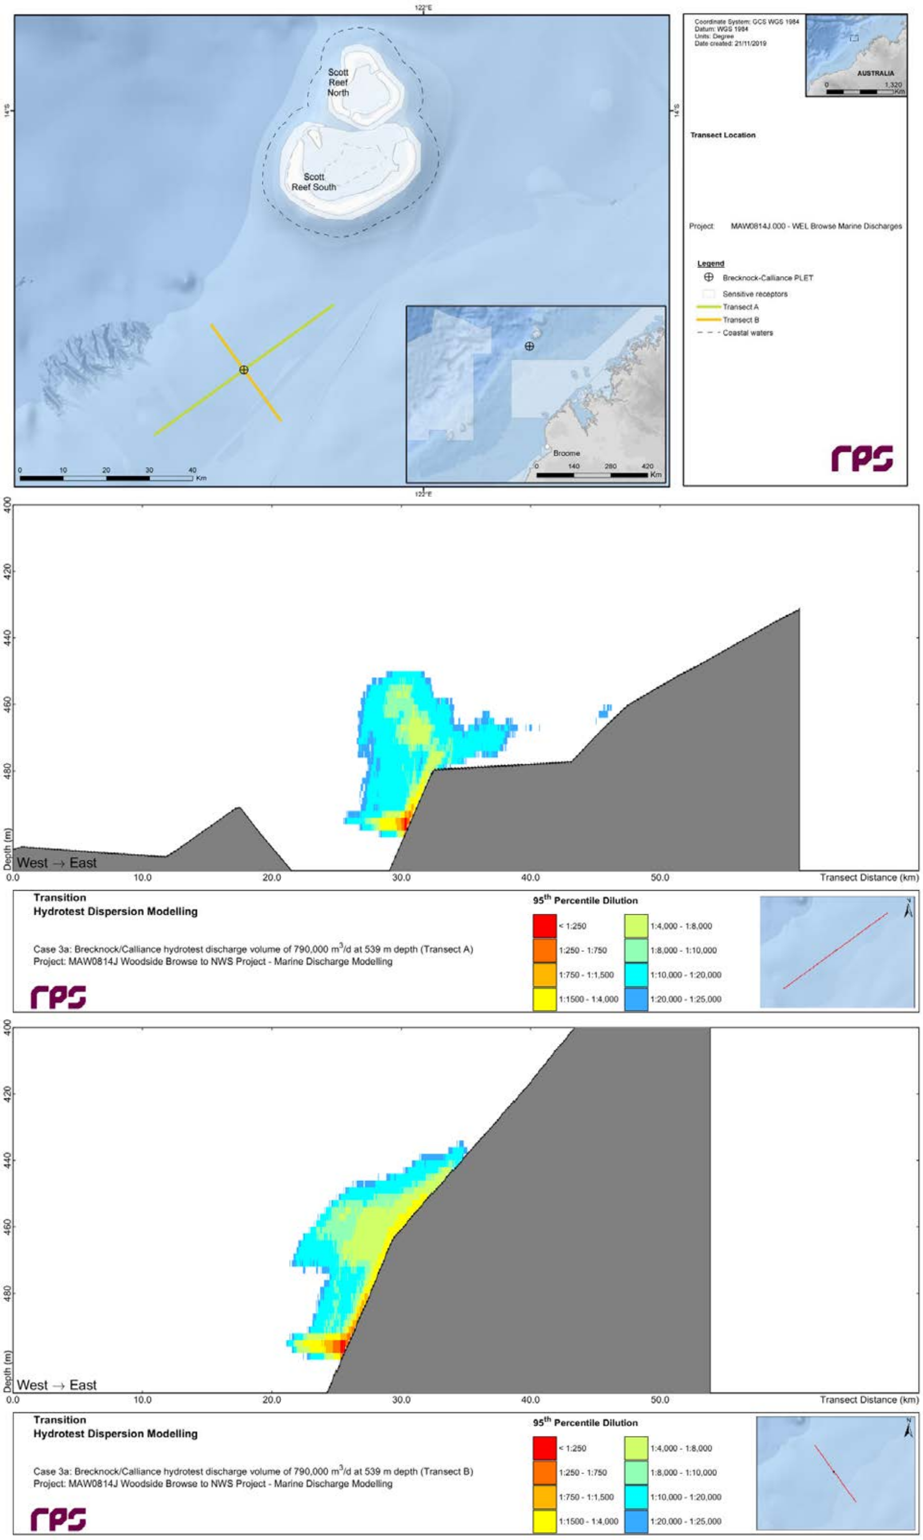

Figure 3.73 Vertical cross-section plots of predicted minimum dilutions at the 95th percentile under transitional conditions for Case H3a (Brecknock/Calliance PLET 790,000 m^3 hydrotest discharge). Transect locations are shown in the top panel, with transect A shown in the middle panel and transect B shown in the bottom panel. Spatial representation of this data is shown in Figure 3.70.

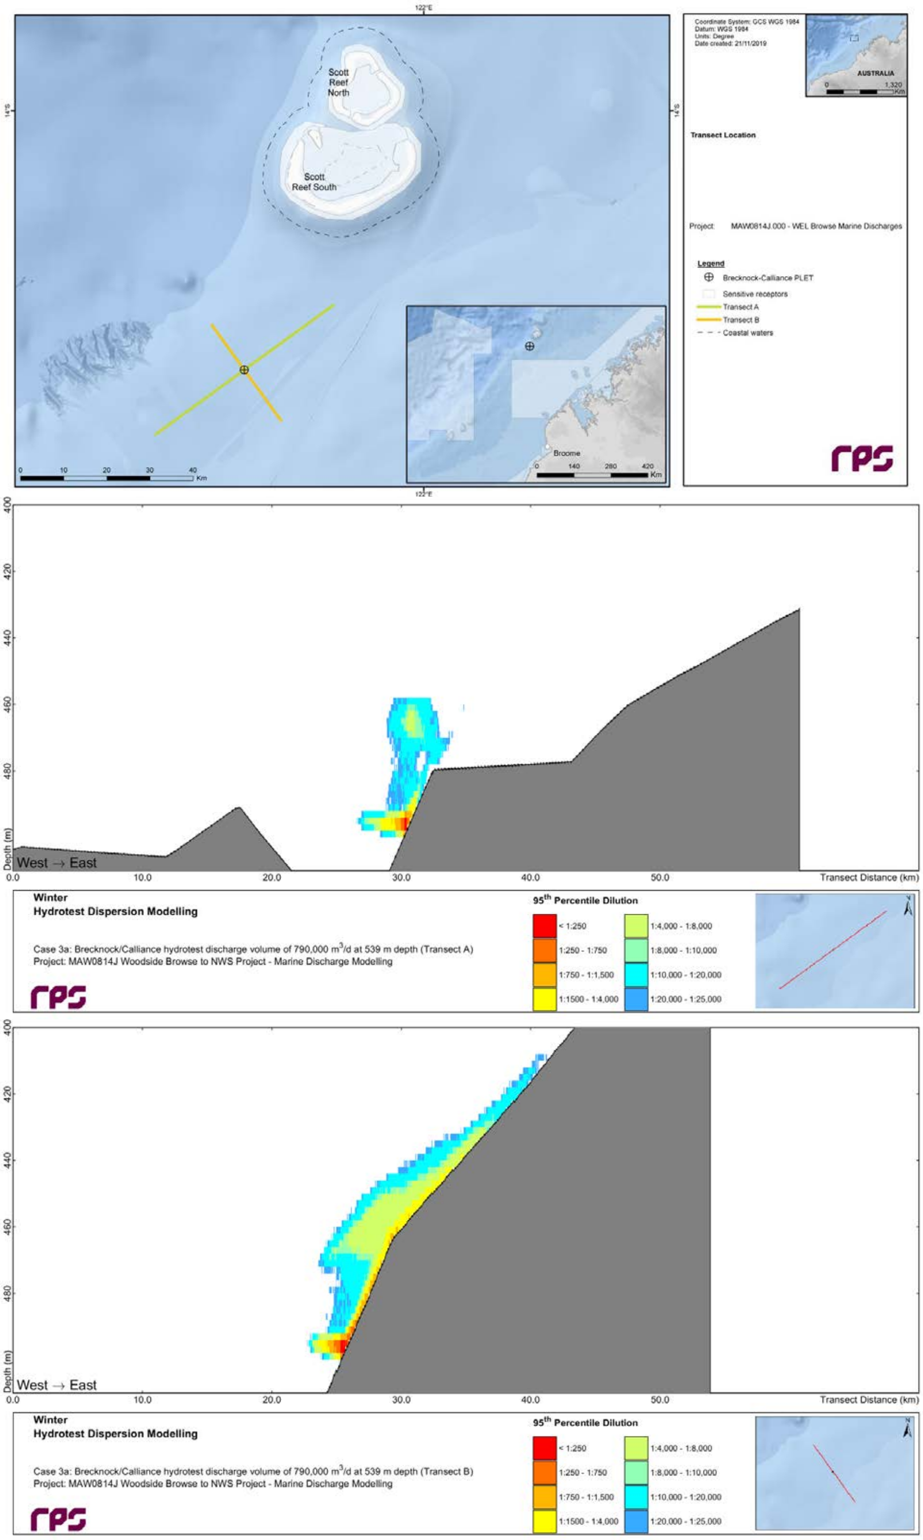

Figure 3.74 Vertical cross-section plots of predicted minimum dilutions at the 95th percentile under winter conditions for Case H3a (Brecknock/Calliance PLET 790,000 m^3 hydrotest discharge). Transect locations are shown in the top panel, with transect A shown in the middle panel and transect B shown in the bottom panel. Spatial representation of this data is shown in Figure 3.71.

3.2.5.2.5 Discharge Case H3b: Torosa PLET Hydrotest Discharge of 56,000 m^3 at 461 m Depth

Table 3.69 Average and minimum dilutions (1:x) achieved at specific radial distances from the hydrotest discharge location in each season for Case H3b (Torosa PLET 56,000 m^3 hydrotest discharge), with application of a rolling 48-hour median to the dilution data.

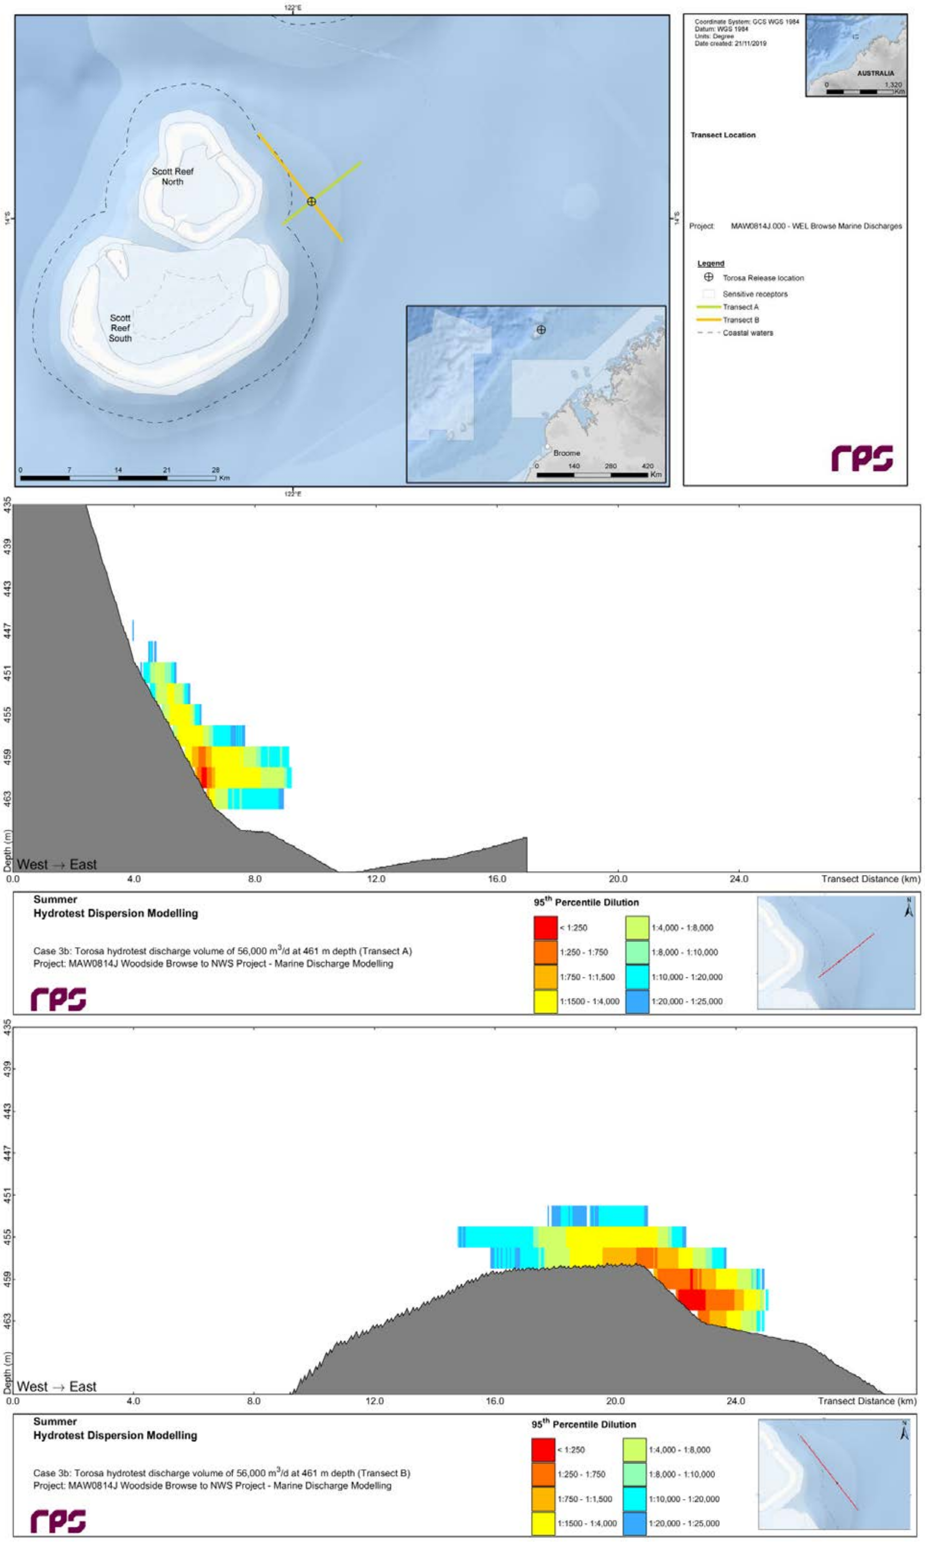

Figure 3.78 Vertical cross-section plots of predicted minimum dilutions at the 95th percentile under summer conditions for Case H3b (Torosa PLET 56,000 m^3 hydrotest discharge). Transect locations are shown in the top panel, with transect A shown in the middle panel and transect B shown in the bottom panel. Spatial representation of this data is shown in Figure 3.75.

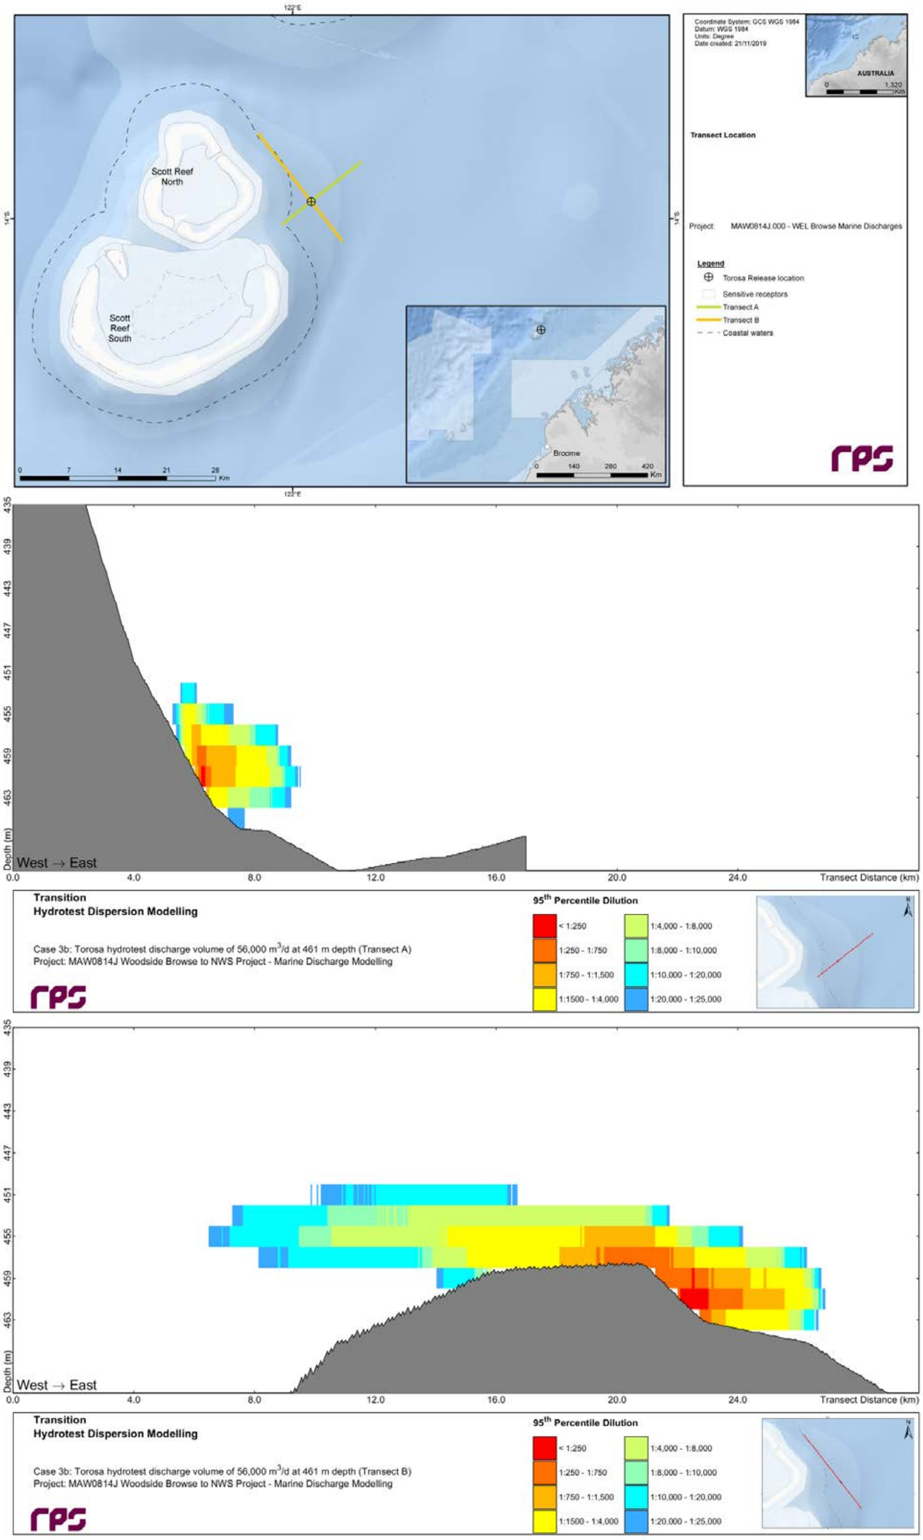

Figure 3.79 Vertical cross-section plots of predicted minimum dilutions at the 95th percentile under transitional conditions for Case H3b (Torosa PLET 56,000 m^3 hydrotest discharge). Transect locations are shown in the top panel, with transect A shown in the middle panel and transect B shown in the bottom panel. Spatial representation of this data is shown in Figure 3.76.

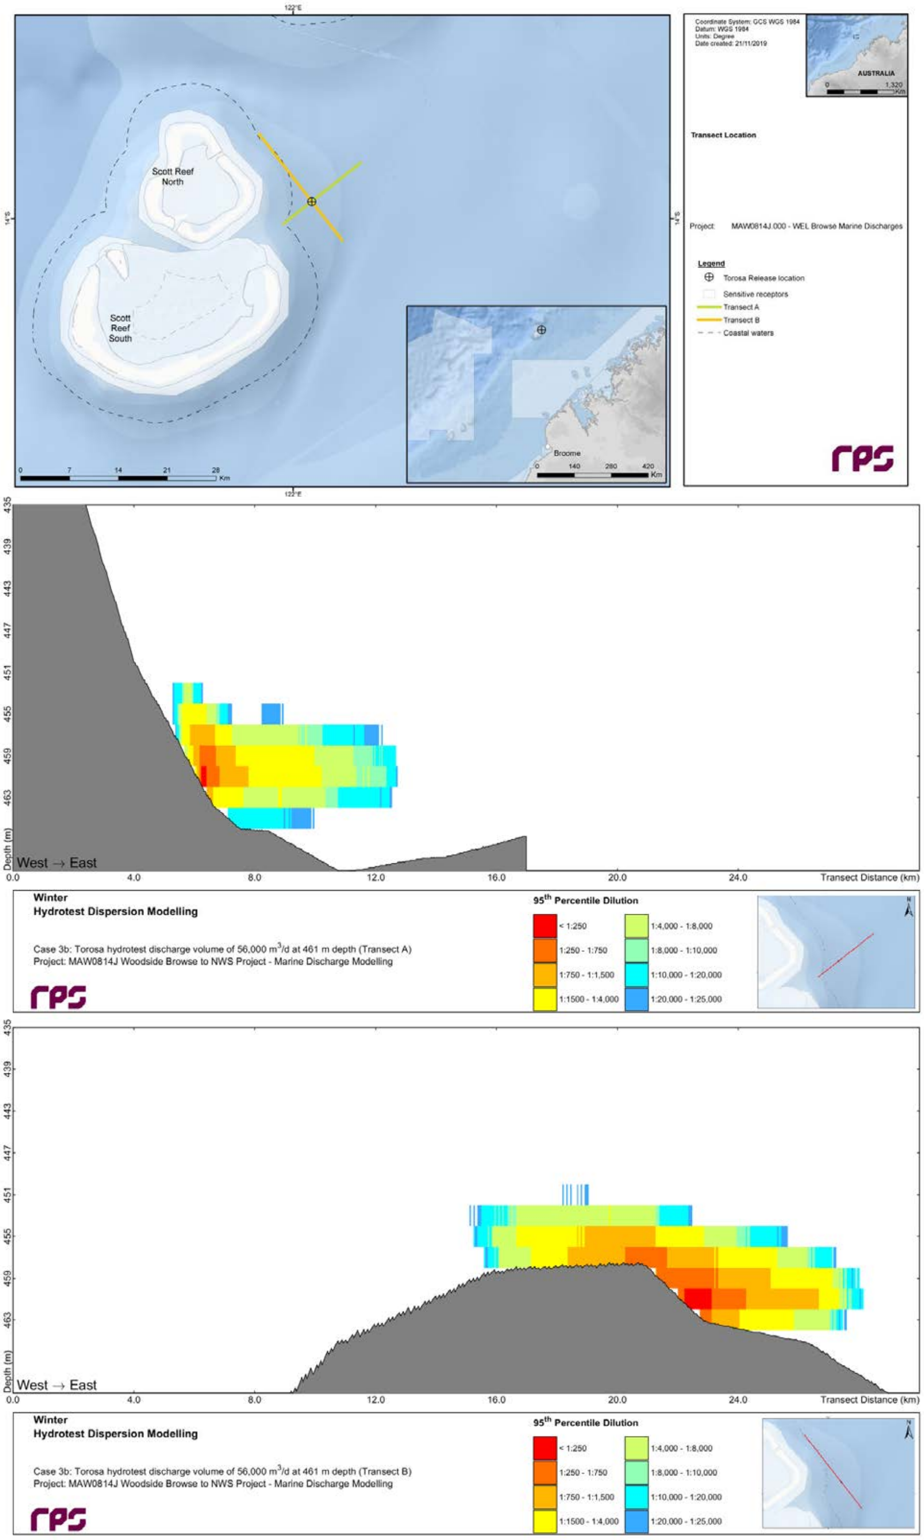

Figure 3.80 Vertical cross-section plots of predicted minimum dilutions at the 95th percentile under winter conditions for Case H3b (Torosa PLET 56,000 m^3 hydrotest discharge). Transect locations are shown in the top panel, with transect A shown in the middle panel and transect B shown in the bottom panel. Spatial representation of this data is shown in Figure 3.77.

3.2.5.3 Annualised Analysis

3.2.5.3.1 Summary

The model outputs for each season (summer, transitional and winter) over the ten-year hindcast period (2006-2015) were combined and analysed on an annualised basis.

Table 3.73, Table 3.76, Table 3.79 and Table 3.82 summarise, for Cases H1, H2, H3a and H3b respectively, the average and minimum dilution achieved at specific radial distances from the discharge location – as well as at or within the boundary of the nearest sensitive receptor – for each percentile over the annual period, with the application of a rolling 48-hour median to the data. The discharge location for Case H1 is distant from Scott Reef and the nearest receptor is Rankin Bank, while for Cases H2, H3a and H3b the nearest receptor is Scott Reef (defined by the 3 nm State water boundary).

The minimum levels of dilution achieved at or within the Scott Reef receptor at the 95th percentile in any season are predicted to be 1:4,440 for Case H2 and 1:2,711 for Case H3b. For Cases H1 and H3a, the discharge locations are sufficiently distant from the nearest receptors – Rankin Bank and Scott Reef, respectively – that the model domains could not encompass the receptors. The expected number of dilutions at the receptors has been inferred from the outcomes at the limits of the model domains. The minimum levels of dilution achieved at the 95th percentile in any season are predicted to be in excess of 1:20,000 at Scott Reef in Case H3a and significantly in excess of 1:20,000 at Rankin Bank in Case H1.

Table 3.74, Table 3.77, Table 3.80 and Table 3.83 provide, for Cases H1, H2, H3a and H3b respectively, summaries of the annualised maximum distances from the discharge location to achieve an example dilution level of 1:10,000 for each percentile. The results indicate that the release of effluent under all seasonal conditions results in slow dispersion within the ambient environment. Dilution to reach the 1:10,000 level at the 95th percentile – this being the maximum spatial extent of the relevant dilution contour from the discharge location in any season – is achieved within a maximum area of influence of: 16.1 km (Case H1), with the maximum extent found to the south-west (Figure 3.81); 12.5 km (Case H2), with the maximum extent found to the north-west (Figure 3.82); 23.4 km (Case H3a), with the maximum extent found to the south-west (Figure 3.83); and 8.2 km (Case H3b), with the maximum extent found to the north-west (Figure 3.84).

Table 3.75, Table 3.78, Table 3.81 and Table 3.84 provide, for Cases H1, H2, H3a and H3b respectively, summaries of the annualised total areas of coverage for the 1:10,000 dilution contour for each percentile. The area of exposure defined by the relevant dilution contour, at the 95th percentile across all seasons, is predicted to reach maximum values of 79.2 km^2 (Case H1), 87.1 km^2 (Case H2), 89.4 km^2 (Case H3a) and 40.8 km^2 (Case H3b).

For Cases H1, H2, H3a and H3b, the aggregated spatial extents of the minimum dilutions at the 95th percentile are presented in Figure 3.81, Figure 3.82, Figure 3.83 and Figure 3.84, respectively. Note that the contours represent the lowest predicted dilution (highest concentration) at any given time step through the water column and do not consider frequency or duration.

The results presented assume that no processes other than dilution would reduce the source concentrations over time, and therefore can be considered as conservative outcomes.

3.2.5.3.2 Discharge Case H1: NRC Tie-In PLET Hydrotest Discharge of 736,000 m^3 at 117 m Depth

Table 3.73 Annualised average and minimum dilutions (1:x) achieved at specific radial distances from the hydrotest discharge location for Case H1 (NRC tie-in PLET 736,000 m^3 hydrotest discharge), with application of a rolling 48-hour median to the dilution data.

† This receptor is outside the model domain and predictions of dilution are unavailable at or within its boundaries. Given the high levels of dilution predicted within the extent of the model domain (20 km) in the direction of Rankin Bank, and the remaining distance (~40 km) from the edge of the model domain to the receptor, it can be assumed that a minimum dilution level of >>20,000 will occur at or within the receptor boundaries at all percentiles.

Table 3.74 Annualised maximum distance from the hydrotest discharge location to achieve 1:10,000 dilution for Case H1 (NRC tie-in PLET 736,000 m^3 hydrotest discharge), with application of a rolling 48-hour median to the dilution data.

Percentile	Season	Maximum distance (m) from discharge location to achieve given dilution
95th	Annual	16,137
99th		22,551
100th		22,925

Table 3.75 Annualised total area of coverage for 1:10,000 dilution for Case H1 (NRC tie-in PLET 736,000 m^3 hydrotest discharge), with application of a rolling 48-hour median to the dilution data.

Percentile	Season	Total area (km^2) of coverage for given dilution
95th	Annual	79.20
99th		217.20
100th		270.40

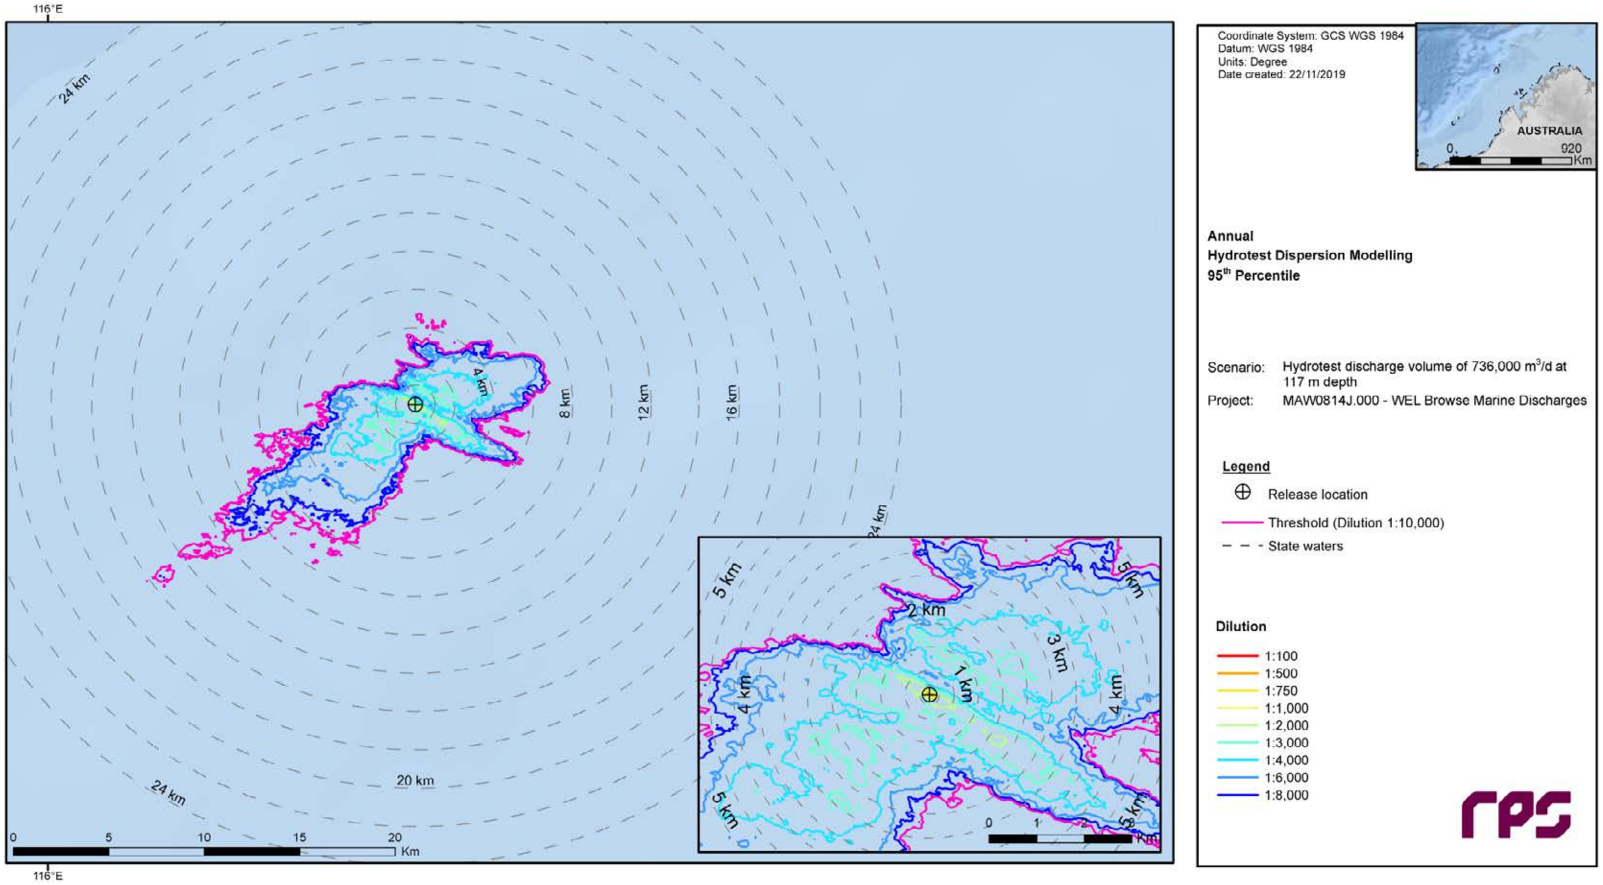

Figure 3.81 Predicted annualised minimum dilutions at the 95th percentile for Case H1 (NRC tie-in PLET 736,000 m^3 hydrotest discharge), with a rolling 48-hour median of the dilution data.

3.2.5.3.3 Discharge Case H2: Torosa PLET Hydrotest Discharge of 846,000 m^3 at 461 m Depth

Table 3.76 Annualised average and minimum dilutions (1:x) achieved at specific radial distances from the hydrotest discharge location for Case H2 (Torosa PLET 846,000 m^3 hydrotest discharge), with application of a rolling 48-hour median to the dilution data.

† This receptor is outside the model domain and predictions of dilution are unavailable at or within its boundaries. Given the high levels of dilution predicted within the extent of the model domain (20 km) in the direction of Scott Reef, and the remaining distance (~12 km) from the edge of the model domain to the receptor, it can be assumed that a minimum dilution level of >20,000 will occur at or within the receptor boundaries at all percentiles.

Table 3.80 Annualised maximum distance from the hydrotest discharge location to achieve 1:10,000 dilution for Case H3a (Brecknock/Calliance PLET 790,000 m^3 hydrotest discharge), with application of a rolling 48-hour median to the dilution data.

Percentile	Season	Maximum distance (m) from discharge location to achieve given dilution
95th	Annual	23,421
99th		26,400
100th		26,502

Table 3.81 Annualised total area of coverage for 1:10,000 dilution for Case H3a (Brecknock/Calliance PLET 790,000 m^3 hydrotest discharge), with application of a rolling 48-hour median to the dilution data.

Percentile	Season	Total area (km^2) of coverage for given dilution
95th	Annual	89.40
99th		324.30
100th		390.50

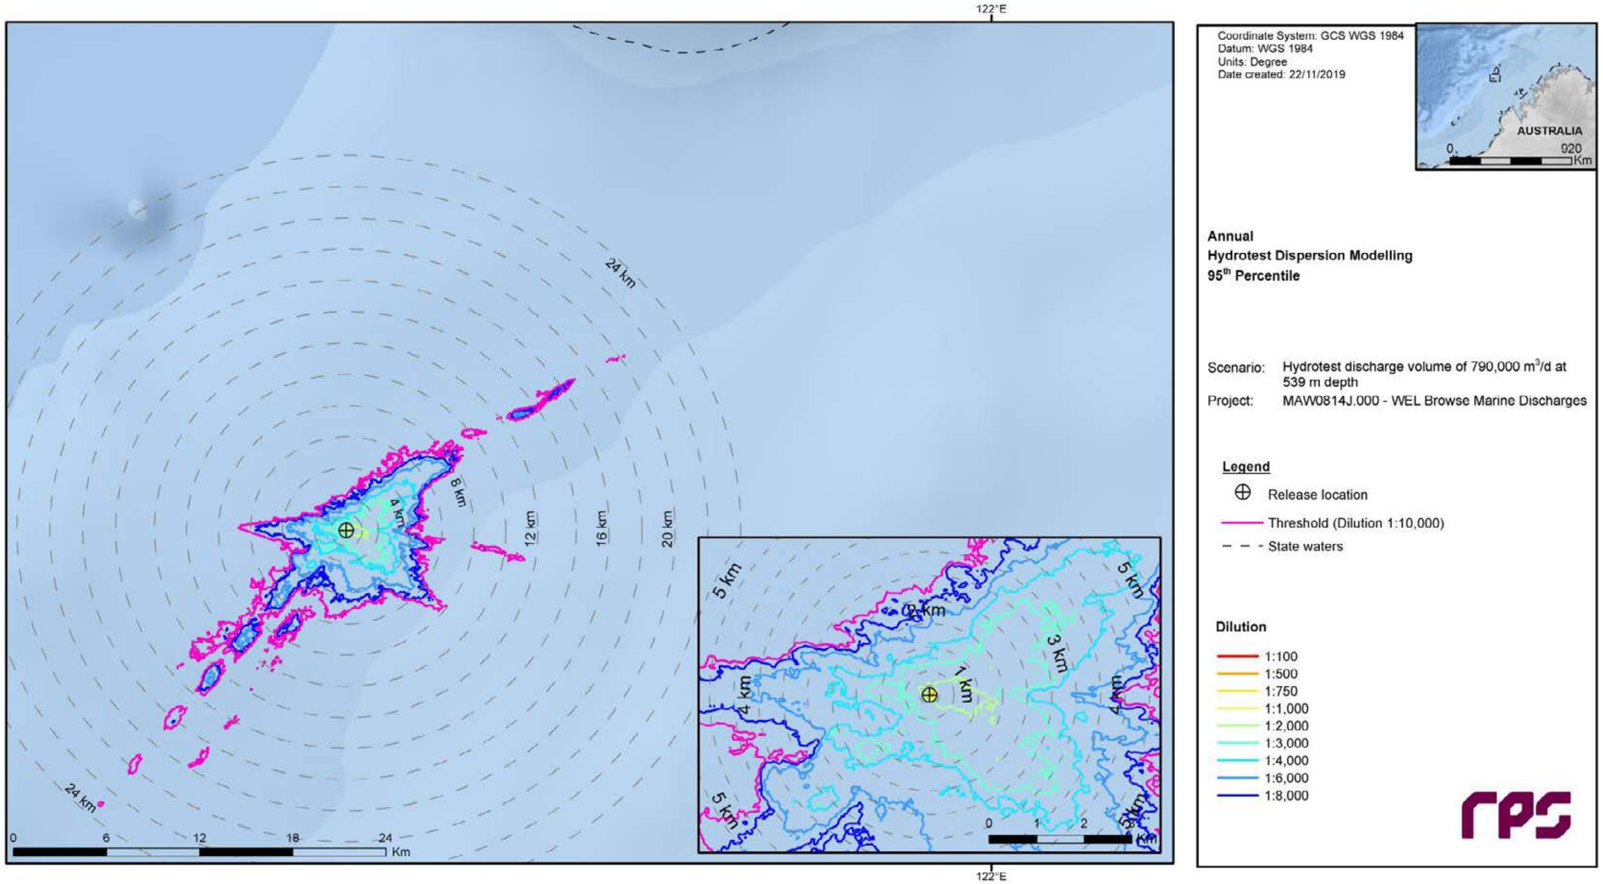

Figure 3.83 Predicted annualised minimum dilutions at the 95th percentile for Case H3a (Brecknock/Calliance PLET 790,000 m^3 hydrotest discharge), with a rolling 48-hour median of the dilution data.

4 CONCLUSIONS

The main findings of the study are as follows:

Near-Field Modelling

Cooling Water Discharges

- The results show that due to the momentum of the discharge a turbulent mixing zone is created in the immediate vicinity of the discharge point, which is 12 m below the water surface (Case C). Medium and strong currents are shown to increase the extent of the turbulent mixing zone. Following this initial mixing, the positively buoyant plume is predicted to rise in the water column.
- The plume is predicted to plunge up to 16 m below the sea surface in all seasons.
- Increased ambient current strengths are shown to increase the horizontal distance travelled by the plume from the discharge point.
- The maximum horizontal distance travelled by the plume under annualised average current speeds is predicted as 37.8 m.
- The maximum diameter of the plume at the end of the near-field zone is predicted as 15.2 m.
- For all seasons, the primary factor influencing dilution of the plume is the strength of the ambient current. Weak currents allow the plume to reach the trapping depth (at which the predictions of dispersion are halted due to the plume reaching equilibrium with the ambient receiving water) closer to the discharge point, which slows the rate of dilution.
- The average dilution levels of the plume upon reaching the trapping depth under annualised average current speeds are predicted to be 1:13.5 for Case C. Additionally, the minimum dilution levels of the plume (i.e. dilution of the plume centreline) upon encountering the trapping depth under annualised average current speeds are predicted to be 1:6.3 for Case C.
- The predictions of dilution rely on the persistence of current speed and direction over time and do not account for any build-up of plume concentrations due to slack currents or current reversals.

Produced Water Discharges

- The results show that due to the momentum of the discharges a turbulent mixing zone is created in the immediate vicinity of the discharge point, which is 14 m below the water surface (Cases P and M). Medium and strong currents are shown to increase the extent of the turbulent mixing zone. Following this initial mixing, the positively buoyant plumes are predicted to rise in the water column.
- For Cases P and M, the plume is predicted to rise towards the water surface after the momentum of the initial discharge is lost.
- Increased ambient current strengths are shown to increase the horizontal distance travelled by the plume from the discharge point.
- For both discharges, the maximum horizontal distance travelled by the plume under annualised average current speeds is predicted as 20.2 m.
- For both discharges, the maximum diameter of the plume at the end of the near-field zone is predicted as 11.7 m.
- For all combinations of discharge case and season, the primary factor influencing dilution of the plume is the strength of the ambient current. Weak currents allow the plume to reach the trapping depth (at which the

predictions of dispersion are halted due to the plume reaching equilibrium with the ambient receiving water) closer to the discharge point, which slows the rate of dilution.

- The average dilution levels of the plume upon reaching the trapping depth under annualised average current speeds are predicted to be 1:204 for Case P and 1:1,222 for Case M. Additionally, the minimum dilution levels of the plume (i.e. dilution of the plume centreline) upon encountering the trapping depth under annualised average current speeds are predicted to be 1:70 for Case P and 1:323 for Case M.

- The predictions of dilution rely on the persistence of current speed and direction over time and do not account for any build-up of plume concentrations due to slack currents or current reversals.

Hydrotest Discharges

- The results show that due to the momentum of the discharges a turbulent mixing zone is created in the immediate vicinity of the discharge points, which are 117 m (Case H1), 461 m (Cases H2 and H3b) and 539 m (Case H3a) below the water surface. Following this initial mixing, the near neutrally buoyant plumes are predicted to travel laterally in the water column.

- Increased ambient current strengths are shown to increase the horizontal distance travelled by the plume from the discharge point.

- For all discharges, the maximum horizontal distance travelled by the plume under annualised average current speeds is predicted as being in the range 50-77 m.

- For all discharges, the maximum diameter of the plume at the end of the near-field zone is predicted as being in the range 16-24 m.

- For all combinations of discharge case and season, the primary factor influencing dilution of the plume is the strength of the ambient current. Weak currents allow the plume to reach the trapping depth (at which the predictions of dispersion are halted due to the plume reaching equilibrium with the ambient receiving water) closer to the discharge point, which slows the rate of dilution.

- The average dilution levels of the plume upon reaching the trapping depth under annualised average current speeds are predicted to be 1:111 for Case H1, 1:166 for Case H2, 1:172 for Case H3a and 1:166 for Case H3b. Additionally, the minimum dilution levels of the plume (i.e. dilution of the plume centreline) upon encountering the trapping depth under annualised average current speeds are predicted to be 1:41 for Case H1, 1:62 for Case H2, 1:65 for Case H3a and 1:62 for Case H3b.

- The predictions of dilution rely on the persistence of current speed and direction over time and do not account for any build-up of plume concentrations due to slack currents or current reversals.

Far-Field Modelling

Cooling Water Discharges

- Instantaneous concentrations (based on a 60-second model time step) are considered when calculating dilution contours.

- The minimum level of dilution achieved at or within the Scott Reef receptor at the 95th percentile in any season is predicted to be 1:125 for Case C.

- For Case C, annualised results show dilution to reach an example level of 1:100 is achieved within an area of influence extending up to 4.2 km at the 95th percentile. The discharged plumes are predicted to travel predominantly along a north-northwest/south-southeast axis throughout the year, which is broadly parallel to the Scott Reef receptor boundary.

- For Case C, annualised results show the area of exposure defined by the 1:100 dilution contour is predicted to reach a maximum value of 3.7 km^2 at the 95th percentile.

- The maximum depth reached by the discharge across all seasons is predicted as 20 m for Case C.
- Considering the relative rates of acclimation of the plume characteristics with the ambient water, the limiting factor for the plume's area of influence is likely to be defined by its chlorine constituent rather than its temperature.
- An example 3 °C plume-ambient temperature differential is forecast to be met within 120 m at the 95th percentile across all seasons.

Produced Water Discharges

- Instantaneous concentrations (based on a 60-second model time step) are considered when calculating dilution contours.
- The minimum levels of dilution achieved at or within the Scott Reef receptor at the 95th percentile in any season are predicted to be 1:1,507 for Case P and 1:17,674 for Case M.
- For Case P, annualised results show dilution to reach an example level of 1:300 is achieved within an area of influence extending up to 0.9 km at the 95th percentile. The discharged plumes are predicted to travel predominantly along a north-northwest/south-southeast axis throughout the year, which is broadly parallel to the Scott Reef receptor boundary, with trajectories to the south-southeast forecast to be longer.
- For Case P, annualised results show the area of exposure defined by the 1:300 dilution contour is predicted to reach a maximum value of 0.7 km^2 at the 95th percentile.
- The maximum depth reached by the discharge across all seasons is predicted as 19 m for Case P.

Hydrotest Discharges

- Concentrations calculated following application of a rolling 48-hour median to the instantaneous data are considered when calculating dilution contours.
- The minimum levels of dilution achieved at or within the nearest receptor at the 95th percentile in any season are predicted to be >>1:20,000 for Case H1 (Rankin Bank), 1:4,440 for Case H2 (Scott Reef), >1:20,000 for Case H3a (Scott Reef) and 1:2,711 for Case H3b (Scott Reef).
- For Cases H1, H2, H3a and H3b, annualised results show dilution to reach an example level of 1:10,000 is achieved within an area of influence extended up to 16.1 km, 12.5 km, 23.4 km and 8.2 km, respectively, at the 95th percentile. The predominant plume travel directions throughout the year are forecast to be south-westerly (Case H1), along a north-northwest/south-southeast axis (Cases H2 and H3a) and along a north-east/south-west axis (Case H3a).
- For Cases H1, H2, H3a and H3b, annualised results show the area of exposure defined by the 1:10,000 dilution contour is predicted to reach a maximum of 79.2 km^2, 87.1 km^2, 89.4 km^2 and 40.8 km^2, respectively, at the 95th percentile.

Key Observations

Cooling Water Discharges

- The discharge will be initially positively buoyant and will rise in the water column, and may resurface in the vicinity of the discharge point prior to acclimation with ambient receiving water conditions.
- At the 95th percentile, plumes for Case C are not expected to reach the Scott Reef 3 nm State water boundary at dilution levels less than 1:125 in any season.

- At the 95th percentile, temperature acclimation of the plume with ambient waters is expected to occur within 120 m of the discharge point in any season and plume temperature will not be a relevant factor at the Scott Reef 3 nm State water boundary.

Produced Water Discharges

- At the 95th percentile, plumes are not expected to reach the Scott Reef 3 nm State water boundary at dilution levels less than 1:1,507 for Case P and 1:17,674 for Case M in any season.

Hydrotest Discharges

- Due to significant variations in the magnitude and directionality of the hindcast currents at each location where potential discharges will occur, predicted outcomes are markedly different.

- Transport patterns will reflect the predominant drift current trajectories at each location, with tidal movements a particularly important driver of dispersion for the deeper discharges. Greater variability in current trajectories is expected near the water surface due to the influence of wind, but, because the plumes are discharged at the seabed and are not positively buoyant, they will not experience these variations.

- At the 95th percentile, plumes are not expected to reach the Scott Reef 3 nm State water boundary at dilution levels less than 1:4,440 for Case H2, 1:20,000 for Case H3a and 1:2,711 for Case H3b in any season. For Case H1, the dilution level of any plumes that may reach Rankin Bank is expected to be significantly greater than 1:20,000.

EXECUTIVE SUMMARY

RPS was commissioned by Woodside Energy Ltd (Woodside) to undertake a quantitative spill risk assessment of hypothetical hydrocarbon spill scenarios related to the proposed Browse Joint Venture (BJV) Browse to North West Shelf Project. The Browse hydrocarbon resource includes the Brecknock, Calliance and Torosa reservoirs, which are approximately 400 km north of Broome.

The primary assessment location is in the vicinity of complex reef structures consisting of Scott Reef North, Scott Reef South and Seringapatam Reef. These are coral atolls that rise steeply from the surrounding shelf.

The main objective of the study was to provide an assessment of the probabilities of oil contact (at greater than defined minimum concentrations), the potential concentrations that might be involved, and the minimum state of weathering of the oil in the case of a release of hydrocarbons. The assessment considers several specific spill scenarios involving different sources, spill durations and oil types, which were defined by Woodside to represent credible scenarios.

Woodside identified four hydrocarbon spill scenarios for investigation, including one two-phase surface/subsea well blowout scenario and three other surface inventory/fuel spill scenarios.

Oil spill modelling was undertaken using a three-dimensional oil spill trajectory and weathering model, SIMAP (Spill Impact Mapping and Analysis Program), which is designed to simulate the transport, spreading and weathering of specific oil types under the influence of changing meteorological and oceanographic forces. Near-field subsea discharge modelling was undertaken using OILMAP, which predicts the droplet sizes that are generated by the turbulence of the discharge as well as the centreline velocity, buoyancy, width and trapping depth (if any) of the rising gas and oil plumes.

To define trends and variations in the potential outcomes of a given scenario, a stochastic modelling process was followed for all scenarios, whereby SIMAP was applied to repeatedly simulate the defined spill scenarios using different samples of current and wind data selected randomly from historic time series data representative of the study area. Results of the repeated simulations were then statistically analysed and mapped to define contours of risk around the release point.

The main findings of this study are as follows:

Metocean Influences

- Tidal flows within the reef complex will have a significant influence on the short-term trajectory of any oil spilled at the modelled release sites, irrespective of the seasonal conditions.
- Large-scale drift currents will have a significant influence on the trajectory of any oil spilled at the modelled release sites, irrespective of the seasonal conditions. The prevailing drift currents will determine the trajectory of oil that is entrained beneath the water surface.
- Interactions with the prevailing wind will provide additional variation in the trajectory of spilled oil, and marked variation in the prevailing drift current and wind conditions will be expected over the duration of a long-term release. This will be expected to increase the spread of hydrocarbons during any single event.

Oil Characteristics

- The unstabilised Torosa Condensate mixture specified for the sea-surface release phase of the Scenario 1 blowout is a pre-processed condensate that is a mixture of volatile and persistent hydrocarbons with significant proportions of highly volatile and residual components. If the sea-surface release phase unstabilised Torosa Condensate mixture is exposed to the atmosphere, around 17% of the mass is expected to evaporate in around 24 hours, another 33% within a few days, and the remaining 51% is expected to persist in the marine environment until decayed due to photochemical and biological degradation. If the unstabilised Torosa Condensate mixture specified for the subsea release phase were to be exposed to the atmosphere, these proportions are expected to be 54%, 21% and 25%, respectively.

- Stabilised Torosa Condensate, which refers to condensate which has been processed by the FPSO and which has been considered in Scenarios 2 and 3, contains a significant proportion of volatile compounds and a low proportion of residual hydrocarbons. If exposed to the atmosphere, around 78% of the mass will be expected to evaporate in around 24 hours, another 8% within a few days, and the remaining 14% will be expected to persist in the marine environment until decayed.
- Marine diesel is a mixture of volatile and persistent hydrocarbons with low percentages of highly volatile and residual components and has been considered in Scenario 4. If exposed to the atmosphere, around 41% of the mass would be expected to evaporate in around 24 hours, another 54% within a few days, and the remaining 5% would be expected to persist in the marine environment until decayed.
- For all hydrocarbon types, the influence of entrainment will regulate the degree of mass retention in the environment.

Summary of Stochastic Assessment Results

Interpretation of Contour Figures

- The mapped spatial outcomes of the stochastic assessment for each scenario are an aggregation of the predicted oil trajectories over the full duration of many individual hydrocarbon spill simulations and indicate the probability of exposure at defined concentrations for individual locations at some point in time after commencement of the spill event.
- These outcomes do not depict a hydrocarbon slick or plume at any particular instant in time, nor do they represent the overall coverage predicted over the full duration of an individual hydrocarbon spill simulation.

Scenario 1: Long-Term (77-Day) Surface/Subsea Blowout of Unstabilised Torosa Condensate at the TRA-C Well

- The location of the release is adjacent to the Scott Reef system. Most of the predicted impacts from this scenario are focused on the receptors that comprise the Scott Reef system. Note that the set of receptor boundaries that define the Scott Reef system for the purposes of this study have some intentional overlapping areas, and this implies duplicated reporting of some oil impacts.
- Floating oil at concentrations equal to or greater than the 10 g/m^2 threshold could potentially be found up to 143 km from the spill site.
- Floating oil concentrations at the 10 g/m^2 threshold are predicted to be focused on the Scott Reef system. Floating oil at 10 g/m^2 reaches Scott Reef North in all replicate simulations, but as Scott Reef North is treated as a submerged feature floating oil is predicted to drift over rather than make direct contact with this receptor. Scott Reef Central – Sandy Islet is treated as an emergent feature. This receptor is predicted to be contacted by floating oil concentrations of 10 g/m^2 with a probability of 8% and a minimum time to contact of 46 hours after commencement of release.
- The Scott Reef Central – Sandy Islet receptor is predicted to experience shoreline oil accumulation in excess of the 100 g/m^2 threshold with a probability of 92%. With regard to shoreline receptors further from the release location, Cartier Island (22%) and Ashmore Reef (18%) are predicted to have the highest probabilities of shoreline oil accumulation in excess of the 100 g/m^2 threshold.
- Potential for accumulation of oil on shorelines is predicted to be significant for Scott Reef Central – Sandy Islet, with a maximum accumulated volume of 827 m^3 and a maximum local accumulated concentration of 34.3 kg/m^2. The predicted zone of shoreline impact is restricted to Sandy Islet. Note that the boundaries of two other receptors, Scott Reef Central and Scott Reef South, overlap with the same shoreline as Scott Reef Central – Sandy Islet so reported accumulations for these receptors are a duplication.
- Entrained oil at concentrations equal to or greater than the 100 ppb threshold is predicted to be found up to approximately 863 km from the spill site.

- Contact by entrained oil at concentrations equal to or greater than 100 ppb is generally predicted for Scott Reef receptors including Scott Reef North (100%). Seringapatam Reef is also predicted to be contacted at 100 ppb (87%).
- The maximum entrained oil concentration forecast for any receptor is predicted as 23.6 ppm at Scott Reef North.
- Dissolved aromatic hydrocarbons at concentrations equal to or greater than the 50 ppb threshold are predicted to be found up to around 673 km from the spill site.
- Contact by dissolved aromatic hydrocarbons at concentrations equal to or greater than 50 ppb is generally predicted for Scott Reef receptors including Scott Reef North (100%). Seringapatam Reef is also predicted to be contacted at 50 ppb (85%).
- The maximum dissolved aromatic hydrocarbon concentration forecast for any receptor is predicted as 13.9 ppm at Scott Reef North.

Scenario 2: Short-Term (24-Hour) Surface Release of Stabilised Torosa Condensate after a Vessel Cargo Tank Rupture at the Torosa FPSO Location

- The location of the release is adjacent to the Scott Reef system. Most of the predicted impacts from this scenario are focused on the receptors that comprise the Scott Reef system.
- Floating oil at concentrations equal to or greater than the 10 g/m^2 threshold could potentially be found up to 126 km from the spill site.
- Floating oil concentrations at the 10 g/m^2 threshold are predicted to be focused on the Scott Reef system. The Scott Reef South and Scott Reef Central shoreline receptors are predicted to be contacted by floating oil concentrations at the 10 g/m^2 threshold with probabilities of 6.5% and 2%, respectively. At these receptors, the corresponding minimum times to contact at this threshold are 21 hours and 57 hours.
- The three Scott Reef receptors that share a common shoreline, Scott Reef South, Scott Reef Central and Scott Reef Central – Sandy Islet, are predicted to experience shoreline oil accumulation in excess of the 100 g/m^2 threshold with a probability of 20.5%.
- Potential for accumulation of oil on shorelines is predicted to be moderate, with a maximum accumulated volume of 212 m^3 and a maximum local accumulated concentration of 9.5 kg/m^2 forecast at the Scott Reef South, Scott Reef Central and Scott Reef Central – Sandy Islet receptors.
- Entrained oil at concentrations equal to or greater than the 100 ppb threshold is predicted to be found up to around 890 km from the spill site.
- Contact by entrained oil at concentrations equal to or greater than 100 ppb is generally predicted for Scott Reef receptors including Scott Reef North (48.5%). Seringapatam Reef is also predicted to be contacted at 100 ppb (22.5%).
- The maximum entrained oil concentration forecast for any receptor is predicted as 30.5 ppm at Scott Reef North. This result is greater than the maximum concentration forecast in Scenario 1, where a larger total volume of oil is released. The difference in maximum entrained oil concentration is attributable to the higher release rate in Scenario 2 (18,000 m^3/day compared to 1,846 m^3/day for Scenario 1). The Scott Reef North receptor is close enough to the release site that the peak concentration is influenced more by the rate of oil released in one day than the total volume of oil released.
- Dissolved aromatic hydrocarbons at concentrations equal to or greater than the 50 ppb threshold are predicted to be found up to around 517 km from the spill site.
- Contact by dissolved aromatic hydrocarbons at concentrations equal to or greater than 50 ppb is generally predicted for Scott Reef receptors including Scott Reef North (41.5%). Seringapatam Reef is also predicted to be contacted at 50 ppb (15.5%).

- The maximum dissolved aromatic hydrocarbon concentration forecast for any receptor is predicted as 12.7 ppm at Scott Reef North.

Scenario 3: Short-Term (Instantaneous) Surface Release of Stabilised Torosa Condensate after an FPSO Offtake System Failure at the Torosa FPSO Location

- The location of the release is adjacent to the Scott Reef system. Most of the predicted impacts from this scenario are focused on the receptors that comprise the Scott Reef system.
- Floating oil at concentrations equal to or greater than the 10 g/m^2 threshold could potentially be found up to 67 km from the spill site.
- The Scott Reef South receptor is predicted to be contacted by floating oil concentrations at the 10 g/m^2 threshold with a probability of 1.5% and a minimum contact time of 24 hours.
- The Scott Reef shoreline, encompassed by the Scott Reef South, Scott Reef Central and Scott Reef Central – Sandy Islet receptors, is predicted to experience shoreline oil accumulation in excess of the 100 g/m^2 threshold with a probability of 2.5%.
- Potential for accumulation of oil on shorelines is predicted to be low, with a maximum accumulated volume of 8 m^3 and a maximum local accumulated concentration of 715 g/m^2 forecast at three Scott Reef shoreline receptors.
- Entrained oil at concentrations equal to or greater than the 100 ppb threshold is predicted to be found up to around 242 km from the spill site.
- Contact by entrained oil at concentrations equal to or greater than 100 ppb is predicted at various northern Scott Reef receptors, including Scott Reef North (28%), Scott Reef North – Flats (25%) and Scott Reef North – Lagoon (20%).
- The maximum entrained oil concentration forecast for any receptor is predicted as 6.4 ppm at Scott Reef North and Scott Reef North – Flats.
- Dissolved aromatic hydrocarbons at concentrations equal to or greater than the 50 ppb threshold are predicted to be found up to around 271 km from the spill site.
- Contact by dissolved aromatic hydrocarbons at concentrations equal to or greater than 50 ppb is predicted at Scott Reef North (23%) and Scott Reef North – Flats (22.5%).
- The maximum dissolved aromatic hydrocarbon concentration forecast for any receptor is predicted as 1.8 ppm at Scott Reef North and Scott Reef North – Lagoon.

Scenario 4: Short-Term (Instantaneous) Surface Release of Marine Diesel after a Vessel Fuel Tank Rupture near the Rowley Shoals

- The location of the release is adjacent to Mermaid Reef. Most of the predicted impacts from this scenario are focused in the vicinity of the Rowley Shoals.
- Floating oil at concentrations equal to or greater than the 10 g/m^2 threshold could potentially be found up to 82 km from the spill site.
- Given that the spill location lies within the Argo-Rowley Terrace Marine Park area, floating oil at concentrations equal to or greater than 10 g/m^2 is forecast at this receptor with a probability of 100% and a minimum time to contact of less than 1 hour. The Rowley Shoals – Mermaid Reef Marine Park shoreline receptor is predicted to be contacted by floating oil concentrations at the 10 g/m^{2}threshold with a probability of 15%, with a corresponding minimum contact time of 5 hours. At the Rowley Shoals – Clerke Reef State Marine Park and Rowley Shoals – Imperieuse Reef State Marine Park shoreline receptors, probabilities of floating oil contact at the 10 g/m^2 threshold are forecast to be 1% or less.

- The Rowley Shoals – Mermaid Reef Marine Park receptor is predicted to experience shoreline oil accumulation in excess of the 100 g/m^2 threshold with a probability of 1%.
- Potential for accumulation of oil on shorelines is predicted to be low, with a maximum accumulated volume of 6 m^3 forecast at the Rowley Shoals – Clerke Reef State Marine Park and a maximum local accumulated concentration of 491 g/m^2 forecast at the Rowley Shoals – Mermaid Reef Marine Park.
- Entrained oil at concentrations equal to or greater than the 500 ppb threshold is predicted to be found up to around 371 km from the spill site.
- Contact by entrained oil at concentrations equal to or greater than 500 ppb is predicted at Argo-Rowley Terrace Marine Park (57%), Rowley Shoals – Mermaid Reef Marine Park (33.5%) and Rowley Shoals – Clerke Reef State Marine Park (7.5%).
- The maximum entrained oil concentration forecast for any receptor is predicted as 167.6 ppm at Argo-Rowley Terrace Marine Park.
- Dissolved aromatic hydrocarbons at concentrations equal to or greater than the 500 ppb threshold are predicted to be found up to around 43 km from the spill site.
- Contact by dissolved aromatic hydrocarbons at concentrations equal to or greater than 500 ppb is predicted at Argo-Rowley Terrace Marine Park (8.5%) and Rowley Shoals – Mermaid Reef Marine Park (1.5%).
- The maximum dissolved aromatic hydrocarbon concentration forecast for any receptor is predicted as 2.2 ppm at Argo-Rowley Terrace Marine Park.

1 INTRODUCTION

1.1 Background

RPS was commissioned by Woodside Energy Ltd (Woodside) to undertake a quantitative spill risk assessment of hypothetical hydrocarbon spill scenarios related to the proposed Browse Joint Venture (BJV) Browse to North West Shelf Project. The Browse hydrocarbon resource is located in the Brecknock, Calliance and Torosa reservoirs located approximately 425 km north of Broome and approximately 290 km off the Kimberley coastline.

The BJV propose to develop the Browse resource using two FPSO facilities with up to 1,100 million standard cubic feet per day (MMscf/d) export capacity (annual daily average). The proposed FPSOs will be supplied by a subsea production system and will export gas to existing North West Shelf (NWS) Project infrastructure via a ~85 km spur line and a ~900 km Browse Trunkline (BTL), which will tie in near the North Rankin Complex (NRC).

Woodside Energy Ltd (Woodside) is Operator for and on behalf of the BJV: Woodside Browse Pty Ltd, Shell Australia Pty Ltd (Shell), BP Developments Australia Pty Ltd (BP), Japan Australia LNG (MIMI Browse) Pty Ltd (MIMI) and PetroChina International Investment (Australia) Pty Ltd (PetroChina).

The assessment focused on the risk of exposure to hydrocarbons for surrounding resources and sensitive receptors if defined spill scenarios were to occur. The main objectives of the study were to provide an assessment, through stochastic spill modelling, of the probabilities of oil contact (at greater than defined minimum concentrations), the potential concentrations that might be involved, and the minimum state of weathering of the oil in case of a release of hydrocarbons.

Woodside identified four hydrocarbon spill scenarios for investigation, including a two phase sea-surface/subsea well blowout and three surface inventory/fuel spills (Woodside, 2019). Each scenario was modelled in a stochastic manner and assessed over an annual period in this study.

The regional context of the spill location for each assessed scenario is shown in Figure 1.1.

The details of the scenarios assessed in this study are summarised in Table 1.1 and listed here:

- Scenario 1: A long-term (77-day) uncontrolled release of 142,154 m^3 of unstabilised Torosa Condensate from the TRA-C well (13° 58' 12.5" S, 121° 58' 37.7" E), with a 5-day surface release phase followed by a 72-day subsea release phase, representing loss of containment after a loss of well control.
- Scenario 2: A short-term (24-hour) uncontrolled surface release of 18,000 m^3 of stabilised Torosa Condensate at the Torosa FPSO location (13° 58' 15.1" S, 122° 01' 28.5" E), representing loss of containment after a vessel cargo tank rupture.
- Scenario 3: A short-term (instantaneous) surface release of 768 m^3 of stabilised Torosa Condensate at the Torosa FPSO location (13° 58' 15.1" S, 122° 01' 28.5" E), representing loss of containment after an FPSO offtake system failure.
- Scenario 4: A short-term (instantaneous) surface release of 2,000 m^3 of marine diesel near the Rowley Shoals (17° 16' 52.8" S, 119° 39' 30.8" E), representing loss of containment after a vessel fuel tank rupture.

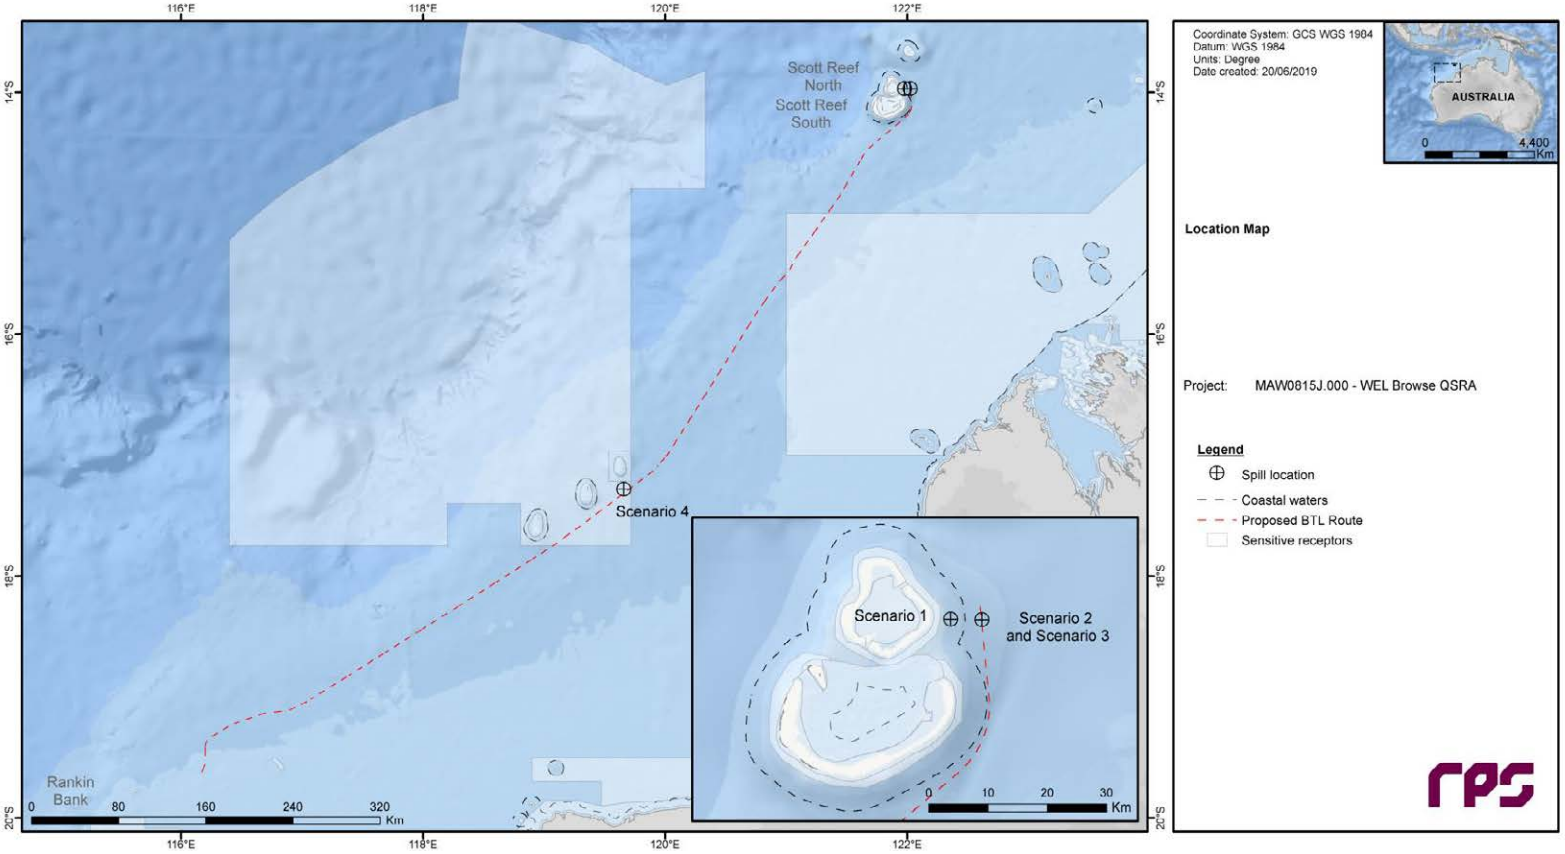

Figure 1.1 Locations of the modelled hydrocarbon spill scenario release sites.

1.2 Stochastic Modelling of Spill Scenarios

Oil spill modelling was undertaken using a three-dimensional oil spill trajectory and weathering model, SIMAP (Spill Impact Mapping and Analysis Program), which is designed to simulate the transport, spreading and weathering of specific oil types under the influence of changing meteorological and oceanographic forces. Near-field subsea discharge modelling was undertaken using OILMAP, which predicts the droplet sizes that are generated by the turbulence of the discharge as well as the centreline velocity, buoyancy, width and trapping depth (if any) of the rising gas and oil plumes.

The SIMAP model simulates both surface and subsea releases and uses the unique physical and chemical properties of an oil type to calculate rates of evaporation and viscosity change, including the tendency to form oil-in-water emulsions. Moreover, the unique transport and dispersion of surface slicks and in-water components (entrained and dissolved) are modelled separately. Thus, the model can be used to understand the wider potential consequences of a spill, including direct contact to slick oil for surface features and exposure to entrained and dissolved oil for organisms in the water column.

To define trends and variations in the potential outcomes of a given scenario, a stochastic modelling scheme was followed in this study, whereby SIMAP was applied to repeatedly simulate the defined spill scenarios using different samples of current and wind data selected randomly from an historic time series of wind and current data representative of the study area. Results of the replicate simulations were then statistically analysed and mapped to define contours of risk around the release point.

For this purpose, a long-term archive of spatially-variable wind and current data covering the Timor Sea and eastern Indian Ocean spanning 10 years (2006-2015, inclusive) was assembled. Current patterns accounted for temporal and spatial variations in large-scale drift currents over the outer shelf waters (typically >200 m depth) together with tidal and wind-driven currents. Modelling was carried out using current and wind data sampled from the data archive to quantify annualised risks of contact at surrounding locations.

Each simulation was run for the duration of the specified spill, plus a further period after the cessation of discharge to allow a sufficient time period for oil concentrations to decrease below the threshold concentrations applied in the analysis. It is expected that remnant floating oil, which may be present at low thresholds at the end of each simulation, would represent highly weathered and degraded products.

It is important to note that the modelling results presented in this document relate to the predicted outcomes once defined spill events have occurred. The probability of the spill scenarios occurring is not considered. The results should therefore be viewed as a guide to the likely outcomes should the spill scenarios occur. Furthermore, the results are presented in terms of statistical probability maps, based on many simulations under different conditions. Different locations within the potential zone of influence would be affected under each different time series of environmental forces. Consequently, these contours for the potential zone of influence will cover a larger area than the area that is likely to be affected during any one single spill event. The contours should therefore be judged as contours of probability and not representations of the area swept by individual spill slicks.

Risk estimates were calculated from the multiple replicate simulations for each assessed scenario, including the probability of contact, the minimum time to contact, and the potential concentrations that might be involved.

The results of the stochastic modelling are presented in Section 3.

Table 1.1 Summary of the hydrocarbon spill scenarios assessed in a stochastic manner in this study.

Scenario	Description	Oil Type	Spilled Volume (m^3)	Release Coordinates	Release Depth (m BMSL)	Spill Duration	Simulation Duration	Period
1	Loss of well control at the TRA-C well	Unstabilised Torosa Condensate	142,154	13° 58' 12.5" S 121° 58' 37.7" E	425	77 days	100 days	Annual
2	Loss of containment after a vessel cargo tank rupture	Stabilised Torosa Condensate	18,000	13° 58' 15.1" S 122° 01' 28.5" E	0	24 hours	56 days	Annual
3	Loss of containment after an FPSO offtake system failure	Stabilised Torosa Condensate	768	13° 58' 15.1" S 122° 01' 28.5" E	0	Instantaneous	42 days	Annual
4	Loss of containment after a vessel fuel tank rupture	Marine Diesel	2,000	17° 16' 52.8" S 119° 39' 30.8" E	0	Instantaneous	42 days	Annual

1.3 Deterministic Analysis

After assessing the stochastic modelling outcomes for all scenarios, Woodside determined there was a requirement for additional model outputs to be provided for selected replicate simulations of each scenario in order to contextualise the stochastic contours.

The results of the deterministic analysis are presented in Section 4.

1.4 Report Structure

The near-field and far-field computational models, risk assessment methodology, environmental data used as input to the models, environmental threshold trigger levels defined for the assessment, characteristics of the oil types used in the modelling of the defined scenarios, and discharge plume characteristics for the subsea release scenario are described in detail in Section 2.

Contour figures and tabulated results showing risk estimates for the receptors nominated by Woodside, produced for defined floating oil, entrained oil and dissolved aromatic hydrocarbon threshold concentrations, are presented in Section 3 to summarise the stochastic modelling outcomes.

Tabulated results for floating oil, entrained oil, dissolved aromatic hydrocarbons and shoreline oil are presented in Section 4 to summarise the outcomes of the deterministic analysis.

The overall findings of the study are summarised in Section 5.

2 MODELLING METHODOLOGY

2.1 Description of the Models

2.1.1 SIMAP

The spill modelling was carried out using a purpose-developed oil spill trajectory and fates model, SIMAP (Spill Impact Mapping and Assessment Program). This model is designed to simulate the transport and weathering processes that affect the outcomes of hydrocarbon spills to the sea, accounting for the specific oil type, spill scenario, and prevailing wind and current patterns.

SIMAP is an evolution of the US EPA Natural Resource Damage Assessment model (French & Rines, 1997; French, 1998; French *et al.*, 1999) and is designed to simulate the fate and effects of spilled oils and fuels for both the surface slick and the three-dimensional plume that is generated in the water column. SIMAP includes algorithms to account for both physical transport and weathering processes. The latter are important for accounting for the partitioning of the spilled mass over time between the water surface (surface slick), water column (entrained oil and dissolved compounds), atmosphere (evaporated compounds) and land (stranded oil). The model also accounts for the interaction between weathering and transport processes.

The physical transport algorithms calculate transport and spreading by physical forces, including surface tension, gravity and wind and current forces for both surface slicks and oil within the water column. The fates algorithms calculate all of the weathering processes known to be important for oil spilled to marine waters. These include droplet and slick formation, entrainment by wave action, emulsification, dissolution of soluble components, sedimentation, evaporation, bacterial and photo-chemical decay and shoreline interactions. These algorithms account for the specific oil type being considered.

Evaporation rates vary over space and time dependent on the prevailing sea temperatures, wind and current speeds, the surface area of the slick and entrained droplets that are exposed to the atmosphere as well as the state of weathering of the oil. Evaporation rates will decrease over time, depending on the calculated rate of loss of the more volatile compounds. By this process, the model can differentiate between the fates of different oil types.

Entrainment, dissolution and emulsification rates are correlated to wave energy, which is accounted for by estimating wave heights from the sustained wind speed, direction and fetch (i.e. distance downwind from land barriers) at different locations in the domain. Dissolution rates are dependent upon the proportion of soluble, short-chained hydrocarbon compounds, and the surface area at the oil/water interface of slicks. Dissolution rates are also strongly affected by the level of turbulence. For example, dissolution rates will be relatively high at the site of the release for a deep-sea discharge at high pressure.

In contrast, the release of hydrocarbons onto the water surface will not generate high concentrations of soluble compounds. However, subsequent exposure of the surface slick to breaking waves will enhance entrainment of oil into the upper water column as oil droplets, which will enhance dissolution of the soluble components. Because the compounds that have high solubility also have high volatility, the processes of evaporation and dissolution will be in dynamic competition with the balance dictated by the nature of the release and the weather conditions that affect the oil after release. The SIMAP weathering algorithms include terms to represent these dynamic processes. Technical descriptions of the algorithms used in SIMAP and validations against real spill events are provided in French (1998), French *et al.* (1999) and French-McCay (2004).

Input specifications for oil types include the density, viscosity, pour-point, distillation curve (volume of oil distilled off versus temperature) and the aromatic/aliphatic component ratios within given boiling point ranges. The model calculates a distribution of the oil by mass into the following components:

- Surface-bound or floating oil.
- Entrained oil (non-dissolved oil droplets that are physically entrained by wave action).
- Dissolved hydrocarbons (principally the aromatic and short-chained aliphatic compounds).

- Evaporated hydrocarbons.
- Sedimented hydrocarbons.
- Decayed hydrocarbons.

2.1.2 OILMAP

SIMAP uses specifications of the depth of release to represent spills onto the water surface or into the water column. For subsea release scenarios, where oil will initially be entrained in the water column as droplets of oil in suspension, it is necessary to define the size-distribution of the droplets and their initial vertical distribution following the initial (within minutes) discharge processes. These processes include the jet induced by the discharge and the dynamic evolution of any associated gas plume. This size distribution will regulate the time for oil droplets to rise to near the sea surface and affect their ability to surface and become floating oil.

High pressure releases (such as a pipeline rupture or gas/oil blowout) tend to generate a distribution with a small to median size (300 µm or less; Johansen, 2003). Due to their larger surface area to volume ratio, droplets of decreasing size will rise under buoyancy at a quadratically slower rate due to viscous resistance exerted by the surrounding water, which can be theoretically derived using Stokes' Law:

$$V = [2 * 9.81 * R^2(\rho_o - \rho_w)] / 9\mu$$

Where: V is the rising velocity of oil droplets; ρ_o and ρ_w are the mass density of oil and water, respectively; R is the radius of the oil droplet; and μ is the dynamic viscosity of water.

If oil is discharged with little or no gas, the oil droplets must rise to the surface under their own buoyancy (resisted by water viscosity) after the dissipation of a relatively short (~1-2 m) discharge jet. However, if gas is discharged with the oil, it will rapidly expand on exiting the pressurised reservoir and continue to expand as it rises and water pressure reduces. As the discharge moves upward, the density difference between the expanding gas bubbles in the plume and the receiving water results in a buoyant force which drives the plume of gas, oil and water towards the surface.

Oil in the release is rapidly mixed by the turbulence in the rising plume. These droplets (typically a few micrometres to millimetres in diameter) are rapidly transported upward by the rising plume; their individual rise velocities contributing little to their upward motion. As the plume rises, it continues to entrain ambient water, which reduces the buoyancy of the mixture and increases the radius of the plume (Chen & Yapa, 2007; Spaulding *et al.*, 2000).

In shallow water (<200 m) the rising plume of gas, oil and water will tend to reach the sea surface before deflecting as a radial, surface flow zone which will spread the oil droplets rapidly away from the centre of the plume (Spaulding *et al.*, 2000). The velocity and oil concentrations in this surface flow zone decrease while the depth of the zone increases. Finally in the far field, where the plume buoyancy has been dissipated, ambient currents and the turbulence generated by wind generated waves will determine the subsequent transport and dispersion of the oil droplets.

As water depths increase, the buoyancy of the rising plume is likely to be lost before the plume reaches the surface, because the gas begins to dissolve into the water column due to increased water temperatures and the density of the plume equalises with the surrounding water (Chen & Yapa, 2007; Spaulding *et al.*, 2000). This results in a situation where the oil droplets will have a further distance to rise to the surface under their own buoyancy and be subject to horizontal displacement due to the prevailing water currents. The reduced velocity of these droplets will also increase their susceptibility to trapping by stratification in the water column, and mixing in the near surface layer (typically 5-10 m depth) generated by surface waves.

As water depths increase further (beyond ~600 m), resulting in higher pressure and colder temperatures at the release depth, a further complication can arise due to part or all of the gas volume converting to a hydrate structure – a solid ice-like lattice structure with specific gravities on the order of 0.92 to 0.96 (Chen & Yapa, 2007; Spaulding *et al.*, 2000). The conversion of the gas into gas-hydrates deprives the plume of its principal source of buoyancy, leaving the oil droplets and gas hydrates to rise a longer distance under their own buoyancy to reach the surface. Hence, oil droplets will have a longer period during which they will be subject to horizontal transport by currents acting at the depth that they occupy.

OILMAP is an oil spill trajectory and fates model extended for the prediction of oil from subsea oil/gas blowouts, including those in deep water (>600 m) where gas hydrate formation can affect the fate of discharged oil (Spaulding *et al.*, 2000). The blowout model predicts the droplet sizes that are generated by the turbulence of the discharge as well as the centreline velocity, buoyancy, width and trapping depth (if any) of the rising gas plume. Inputs to the model include the depth (hence water pressure); discharge rate; hole size; oil density and viscosity, and the vertical temperature/salinity profile of the receiving water. This model was applied to supply the droplet size distribution and the plume dimensions to the SIMAP model, for the long-term discharge simulations.

2.2 Calculation of Exposure Risks

The stochastic model within SIMAP performs a large number of simulations for a given spill site, randomly varying the spill time for each simulation. The model uses the spill time to select samples of current and wind data from a long time series of wind and current data for the area. Hence, the transport and weathering of each slick will be subject to a different sample of wind and current conditions.

This stochastic sampling approach provides an objective measure of the possible outcomes of a spill, because environmental conditions will be selected at a rate that is proportional to the frequency that these conditions occur over the study region. More simulations will tend to use the most commonly occurring conditions, while conditions that are more unusual will be represented less frequently.

During each simulation, the SIMAP model records the location (by latitude, longitude and depth) of each of the particles (representing a given mass of oil) on or in the water column, at regular time steps. For any particles that contact a shoreline, the model records the accumulation of oil mass that arrives on each section of shoreline over time, less any mass that is lost to evaporation and/or subsequent removal by current and wind forces.

The collective records from all simulations are then analysed by dividing the study region into a three-dimensional grid. For oil particles that are classified as being at the water surface (floating oil), the sum of the mass in all oil particles (including accounting for spreading and dispersion effects) located within a grid cell, divided by the area of the cell provides estimates of the concentration of oil in that grid cell, at each time step. For entrained and dissolved oil particles, concentrations are calculated at each time step by summing the mass of particles within a grid cell and dividing by the volume of the grid cell.

The concentrations of oil calculated for each grid cell, at each time step, are then analysed to determine whether concentration estimates exceed defined threshold concentrations over time.

Risks are then summarised as follows:

- The probability of exposure to a location is calculated by dividing the number of spill simulations where any instantaneous contact occurred above a specified threshold at that location by the total number of replicate spill simulations. For example, if contact occurred at a location (above a specified threshold) during 21 out of 100 simulations, a probability of exposure of 21% is indicated.
- The minimum potential time to a shoreline location is calculated by the shortest time over which oil at a concentration above a particular threshold was calculated to travel from the source to the location in any of the replicate simulations.
- The maximum potential concentration of oil predicted for each shoreline section is the greatest mass per m^2 of shoreline calculated to strand at any location within that section during any of the replicate simulations.
- The average of the maximum concentrations of oil predicted to potentially accumulate on each shoreline section is calculated by determining the greatest mass per m^2 of shoreline during each replicate simulation and calculating an average of these estimates across the simulations.

- Similar treatments are undertaken for entrained oil and dissolved aromatic hydrocarbons.

Thus, the minimum time to shoreline and the maximum potential concentration estimates indicate the worst potential outcome of the modelled spill scenario for each section of shoreline. However, the average over the replicates presents an average of the potential outcomes, in terms of oil that could strand.

Note also that results quoted for sections of shoreline or shoal are derived for any individual location within that section or shoal, as a conservative estimate. Locations will represent shoreline lengths of the order of ~1 km, while sections or regions will represent shorelines spanning tens to hundreds of kilometres and we do not imply that the maximum potential concentrations quoted will occur over the full extent of each section. We therefore warn against multiplying the maximum concentration estimates by the full area of the section because this will greatly overestimate the total volume expected on that section.

The maximum entrained hydrocarbon and maximum dissolved aromatic hydrocarbon concentration are calculated for water locations surrounding each defined shoreline (see Section 3.1). These zones are defined to provide a buffer area around shallow (<10 m) habitats to allow for spatial errors in model forecasts. The greatest calculated value at any time step during any replicate simulation is listed. These values therefore represent worst-case localised estimates (within a grid cell). The averages over all replicate values represent a central tendency of these simulated worst-case estimates.

2.3 Inputs to the Risk Assessment

2.3.1 Current Data

2.3.1.1 Background

The area of interest for this study is located within the influence of the Indonesian Throughflow, a large-scale current system characterised as a series of migrating gyres and connecting jets that are steered by the continental shelf. While the mass flow is generally towards the south-west, year-round, the internal gyres generate local currents in all directions. As these gyres migrate through the area, large spatial variations in the speed and direction of currents will occur at a given location over time. Further south of the project area, the Leeuwin Current becomes the dominant large-scale current system, flowing poleward down the pressure gradient along the Western Australian coastline and past Cape Leeuwin.

Offshore regions with water depths exceeding 100-200 m experience significant large-scale drift currents. These drift currents can be relatively strong (1-2 knots) and complex, manifesting as a series of eddies, meandering currents and connecting flows. These offshore drift currents also tend to persist longer (days to weeks) than tidal current flows (hours between reversals) and thus will have greater influence upon the net trajectory of plumes over time scales exceeding a few hours.

On the continental shelf, in shallower waters around Scott Reef and closer to the inshore region of the Kimberley Coast, surface winds and tidal dynamics dominate over the large scale current flows (Condie & Andrewartha, 2008). In comparison to drift currents, tidal currents generate only relatively short tidal migrations (distance travelled by a parcel of water over a tidal cycle) that follow an elliptical path with a period of about 12 hours in the study region. Hence, tidal currents add variability to the longer-term drift patterns of an entrained plume.

Wind shear on the water surface also generates local-scale currents that can persist for extended periods (hours to days) and result in long trajectories. Persistent winds along the mainland coast can induce Ekman transport, where surface waters move offshore and facilitate upwelling events in which cold nutrient-rich waters from the deep Indian Ocean are brought to the surface. However, due to the opposing transport of warm tropical waters by the Leeuwin Current, large-scale persistent upwelling along the Western Australian coast is suppressed. Therefore, upwelling events are sporadic, short-term and localised to areas of the coastline where the continental shelf narrows, including the area around the Capes and the Ningaloo coast (IMOS, 2015). This process is seasonal/transient and affected by the strength of the Leeuwin Current, with minimal upwelling in times with strong Leeuwin Current flow.

The current-induced transport of plumes can be variably affected by combinations of tidal, wind-induced and density-induced drift currents. Depending on their local influence, it is critical to consider all these potential advective mechanisms to rigorously understand patterns of potential transport from a given discharge location.

To appropriately allow for temporal and spatial variation in the current field, dispersion modelling requires the current speed and direction over a spatial grid covering the potential migration trajectories of plumes. As long-term measured current data is not available for simultaneous periods over a network of locations covering the offshore areas relevant to this study, the analysis relied upon hindcasts of the circulation generated through numerical modelling by internationally recognised organisations.

A composite modelled ocean current data product was derived by combining predictions of mesoscale circulation currents, available at daily resolution from global ocean models, with predictions of the hourly tidal currents generated by the RPS HYDROMAP model. By combining a drift current model with a tidal model, the influences of inter-annual and seasonal drift patterns, and the more regular variations in tide, were depicted, ensuring nearshore and offshore hydrodynamic processes were represented.

2.3.1.2 Mesoscale Circulation

2.3.1.2.1 Description of Mesoscale Model: BRAN

Two mesoscale ocean current data sets were considered for the study: the CSIRO (Commonwealth Scientific and Industrial Research Organisation) global ocean model, BRAN (Bluelink ReANalysis); and the HYCOM (Hybrid Coordinate Ocean Model) Consortium's global ocean model, HYCOM. Based on a hydrodynamic model validation conducted by RPS, the output of the BRAN (Oke *et al.*, 2008, 2009; Schiller *et al.*, 2008) ocean model, which is sponsored by the Australian Government through the Commonwealth Bureau of Meteorology (BoM), Royal Australian Navy and CSIRO, was chosen for representation of the drift currents that affect the area. BRAN is a data-assimilative, three-dimensional ocean model that has been run as a hindcast for many periods and is now used for ocean forecasting (Schiller *et al.*, 2008).

BRAN routinely assimilates sea level anomaly data, tide gauge data, sea surface temperature and in situ temperature and salinity measurements (Oke *et al.*, 2009). Comparisons of BRAN hindcast outputs to satellite and independent in situ observations found that BRAN was reliably representing the broad-scale ocean circulation, the mesoscale surface eddy field, and shelf circulation around Australia (Oke *et al.*, 2008; Schiller *et al.*, 2008). Additionally, reanalysis of past periods using the BRAN model has been shown to realistically represent upwelling events, in particular along the Bonney Coast of South Australia, a region of frequent wind-driven upwellings (Oke *et al.*, 2009).

The BRAN predictions for drift currents are produced at a horizontal spatial resolution of approximately 0.1° over the region, at a frequency of once per day, averaged over the 24-hour period. Hence, the BRAN model data provides estimates of mesoscale circulation with horizontal resolution suitable to resolve eddies of a few tens of kilometres' diameter, as well as connecting stream currents of similar spatial scale. Drift currents that are represented over the inner shelf waters in the BRAN data are principally attributable to wind induced drift.

There are several versions of the BRAN database available. The latest BRAN simulation spans the period of January 1994 to August 2016. From this database, three-dimensional data representing horizontal water movement at discrete depths was extracted for all points in the model domain for the years 2006-2015 (inclusive). The data was assumed to be a suitably representative sample of the current conditions over the study area for future years.

Although this data should represent effects of upwelling and downwelling processes on horizontal transport at a given depth, the data does not explicitly represent vertical currents between horizontal layers. This was considered reasonable because vertical currents associated with episodic upwelling and downwelling events are relatively small in magnitude (3-30 cm/s; Kampf *et al.*, 2004) compared to horizontal currents represented in the tidal and non-tidal current data (0.5-2 m/s), and considering allowances for dispersion rates in the horizontal (0.1-50 m/s) and vertical (1-10 cm/s) planes.

2.3.1.2.2 Mesoscale Current Validation

The suitability of the BRAN ocean model product was evaluated by comparing the predicted currents to those measured within the Browse project area. The validation included both quantitative and qualitative comparisons between measured and modelled data at a range of depths through the water column, at three available measurement locations shown in Figure 2.1: Browse C1-1 (three depth layers), B2-1 (eight depth layers) and G2-1 (three depth layers).

Time series comparisons of modelled and measured current magnitude, direction, and U/V velocity components are presented for sites B2-1 (Figure 2.2 and Figure 2.3), C1-1 (Figure 2.4 and Figure 2.5) and G2-1 (Figure 2.6 and Figure 2.7). For the purposes of brevity and clarity, only a surface and mid-depth time series at each site was selected for presentation. The time series comparisons revealed that, at two of the sites (B2-1 and G2-1), the BRAN model offered a good match in magnitude and direction of the measured current velocity in the upper water column; however, the magnitudes of the peaks and troughs were often underpredicted at the deeper levels. At the C1-1 site, the BRAN model captured the range in current magnitude at each depth; however, the timing of peaks and troughs in the measured current velocity and direction was not well-matched. Given the location of this site in close proximity to Scott Reef, with steep gradients in the bathymetry and the relatively coarse resolution of the ocean model (relative to the tidal model), this was not unexpected.

A quantitative analysis of the BRAN model's skill at replicating the drift currents was conducted using the Index of Agreement (IOA), presented in Willmott (1981) and Willmott *et al.* (1985), and the Mean Absolute Error (MAE), discussed in Willmott (1982) and Willmott & Matsuura (2005). A perfect agreement can be said to exist between the model and field observations if the IOA gives a measure of one, and complete disagreement will produce an IOA measure of zero (Willmott, 1981). The MAE is simply the average of the absolute values of the differences between the observed and modelled values.

The IOA and MAE values derived from comparisons of the U/V velocity components over the full measurement period at sites B2-1, C1-1 and G2-1 for all available water depths are presented in Table 2.1. The results confirm the conclusions drawn from analysis of the comparison time series plots. The IOA for both velocity components is good at sites B2-1 and G2-1 in the upper water column but reduces at deeper layers. This reflects the generally good match in the range, magnitude and direction of the measured and modelled drift currents at these sites, particularly in the upper water column. The IOA for both velocity components at site C1-1 is low, suggesting a poor agreement, reflecting the poor match in the timing of peaks and troughs in velocity observed in the time series plots.

Overall, the BRAN model data offered a reasonable match to the field measurements within the Browse project area, particularly in the upper water column. Given the stochastic methodology applied in far-field modelling, the use of a ten-year hindcast of BRAN current data allowed a realistic spatial distribution of potential plume trajectories and extents to be captured in aggregate. The BRAN model was considered suitable for use in the marine dispersion modelling studies.

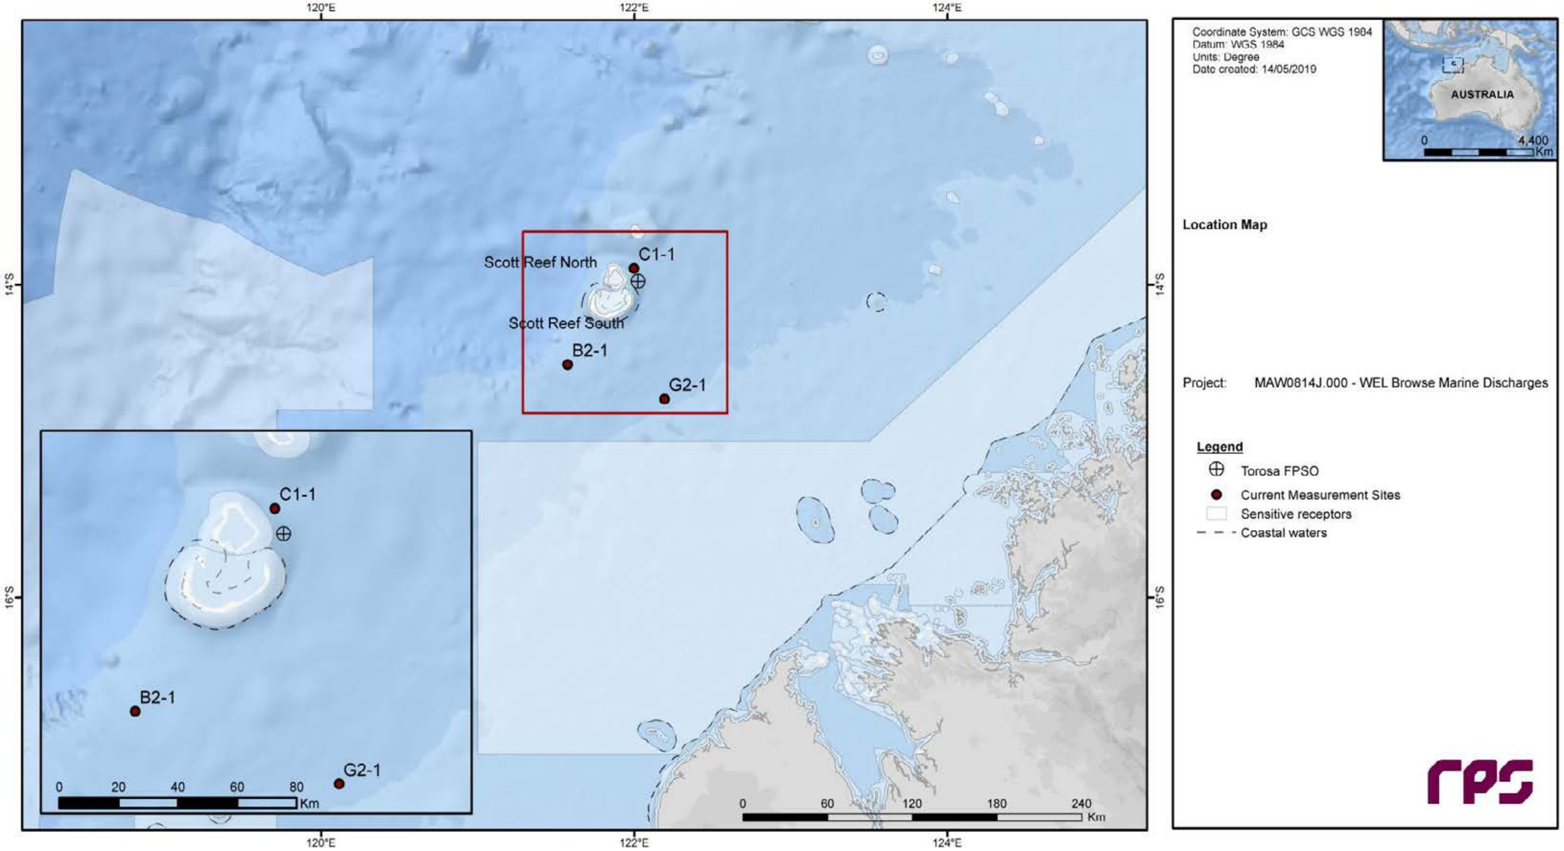

Figure 2.1 Locations of the proposed Torosa FPSO and the current measurement sites used for model validation, in proximity to Scott Reef, off the Kimberley Coast of Western Australia.

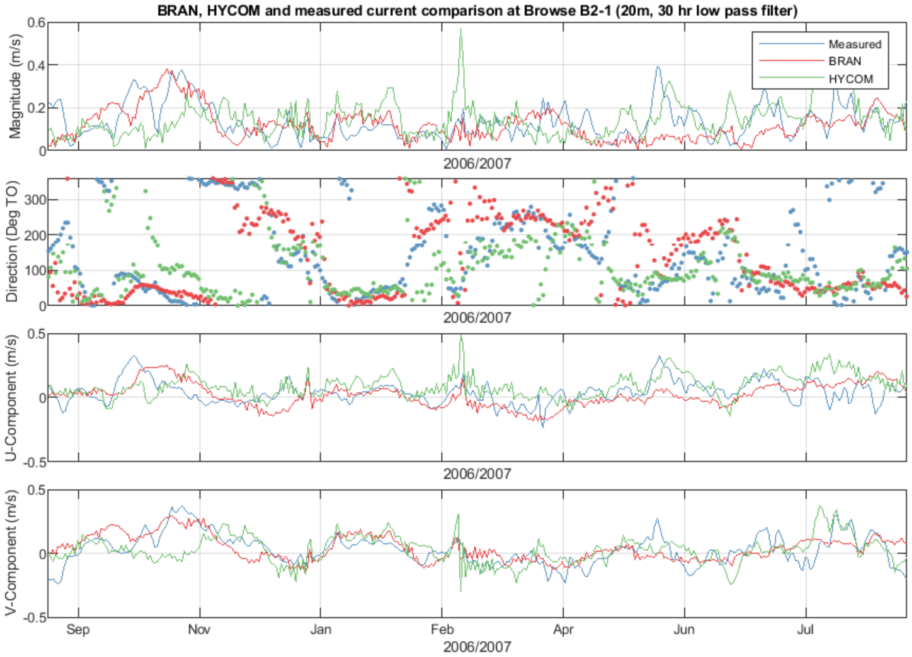

Figure 2.2 Comparisons between BRAN-predicted (red line), HYCOM-predicted (green line) and measured (blue line) non-tidal current data at site B2-1, at a depth of approximately 20 m, for the period of August 2006 to July 2007.

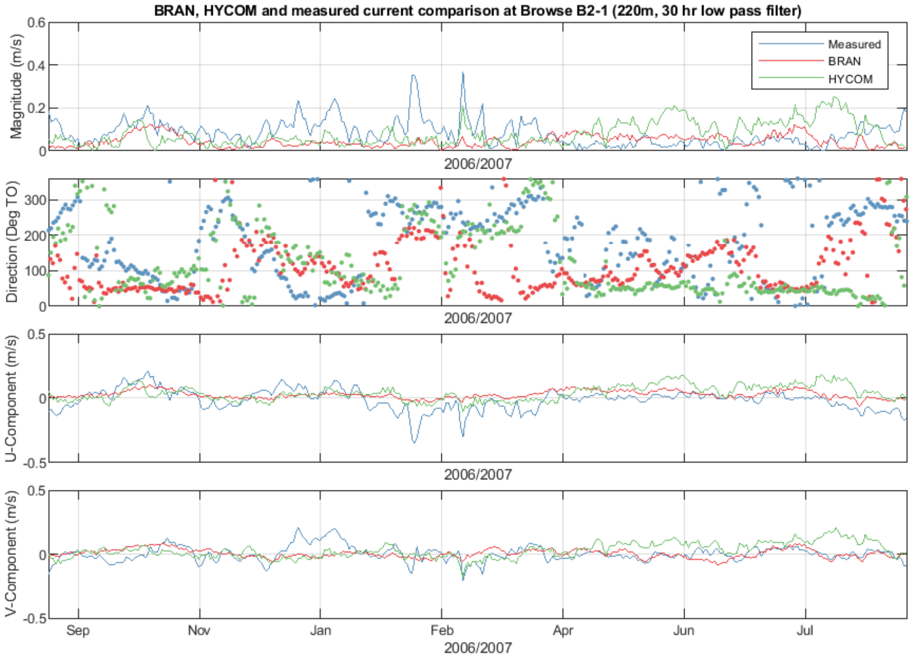

Figure 2.3 Comparisons between BRAN-predicted (red line), HYCOM-predicted (green line) and measured (blue line) non-tidal current data at site B2-1, at a depth of approximately 220 m, for the period of August 2006 to July 2007.

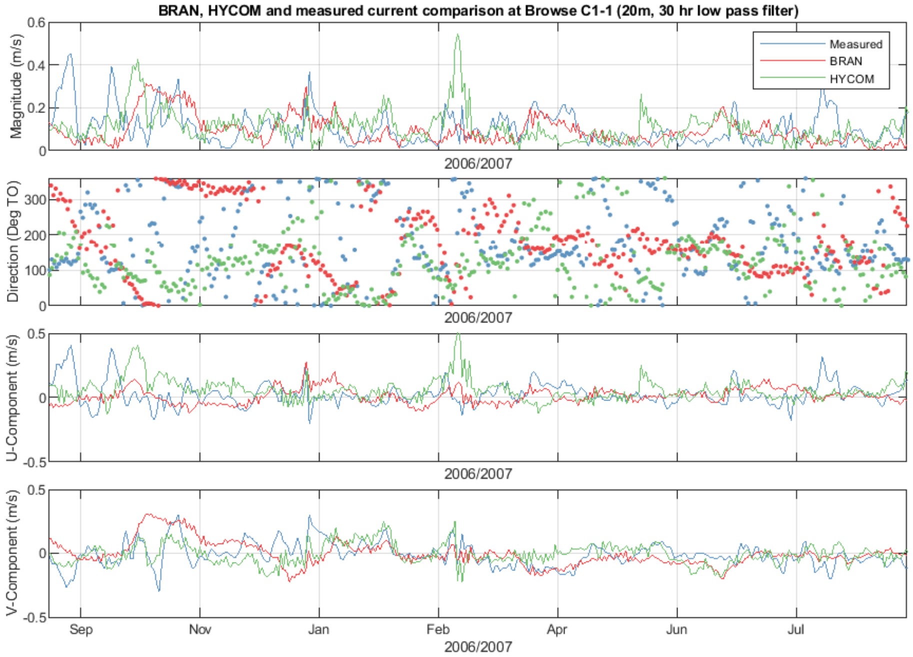

Figure 2.4 Comparisons between BRAN-predicted (red line), HYCOM-predicted (green line) and measured (blue line) non-tidal current data at site C1-1, at a depth of approximately 20 m, for the period of August 2006 to July 2007.

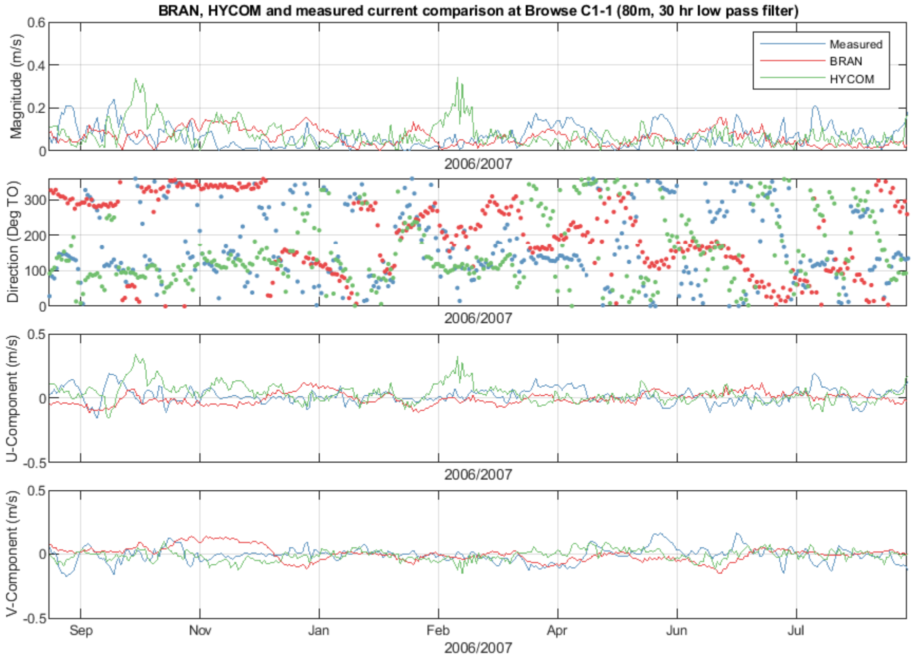

Figure 2.5 Comparisons between BRAN-predicted (red line), HYCOM-predicted (green line) and measured (blue line) non-tidal current data at site C1-1, at a depth of approximately 80 m, for the period of August 2006 to July 2007.

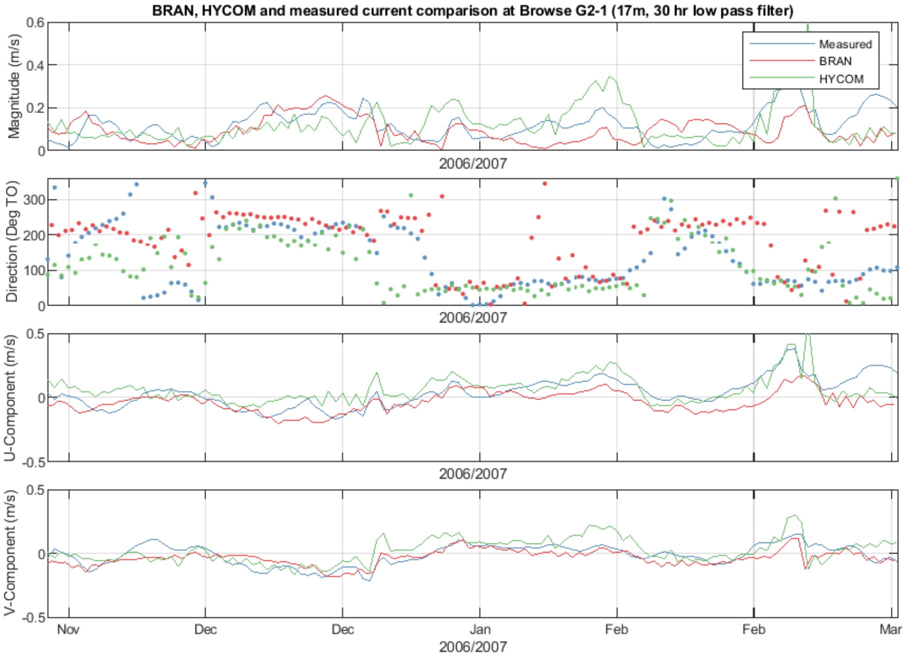

Figure 2.6 Comparisons between BRAN-predicted (red line), HYCOM-predicted (green line) and measured (blue line) non-tidal current data at site G2-1, at a depth of approximately 17 m, for the period of August 2006 to July 2007.

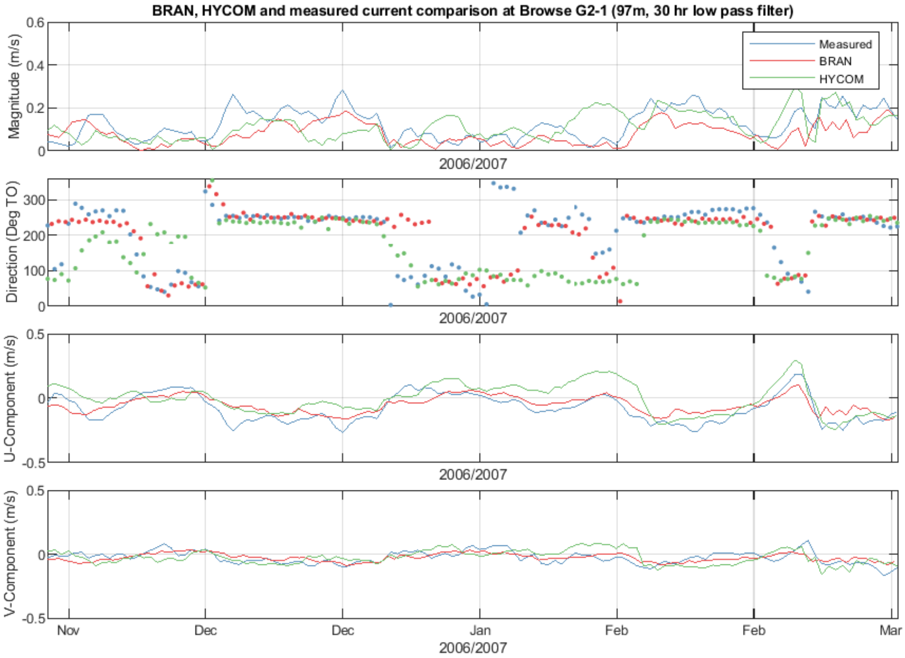

Figure 2.7 Comparisons between BRAN-predicted (red line), HYCOM-predicted (green line) and measured (blue line) non-tidal current data at site G2-1, at a depth of approximately 97 m, for the period of August 2006 to July 2007.

Table 2.1 Statistical comparison of BRAN-predicted and measured non-tidal current speeds along orthogonal component axes at the three measurement sites (2006-2007).

Site	Depth (m)	IOA		MAE (m/s)	
		U Component	V Component	U Component	V Component
B2-1	20.0	0.65	0.76	0.08	0.08

2.3.1.2.3 Mesoscale Currents at the Spill Locations

Figure 2.8 and Figure 2.9 show the monthly distributions of current speeds and directions for the BRAN data points closest to the spill locations for Scenarios 1 to 3 and Scenario 4, respectively. Note that the convention for defining current direction is the direction towards which the current flows.

The data indicates that higher average current speeds are characteristic of the November to March period, with the highest average speeds (0.14 m/s) occurring near the Scenario 1 to 3 spill sites in November. Lower average current speeds are more common during the April to September period, with the lowest average speeds (0.04 m/s) occurring near the Scenario 1 to 3 spill sites in August. Peak current speeds across all months and sites are approximately 0.40 m/s.

The prevailing current direction at the spill sites varies throughout the year, with north-easterly currents dominant between November and February and south-westerly currents dominant in April and May. Current directions during the March and June to October periods are variable across all sites.

The extracted current data near the spill locations provides an insight into the expected initial behaviour of any released oil due to the drift currents alone. Oil moving beyond the release sites, particularly towards the coast, would be subject to considerable variation in the drift current regime.

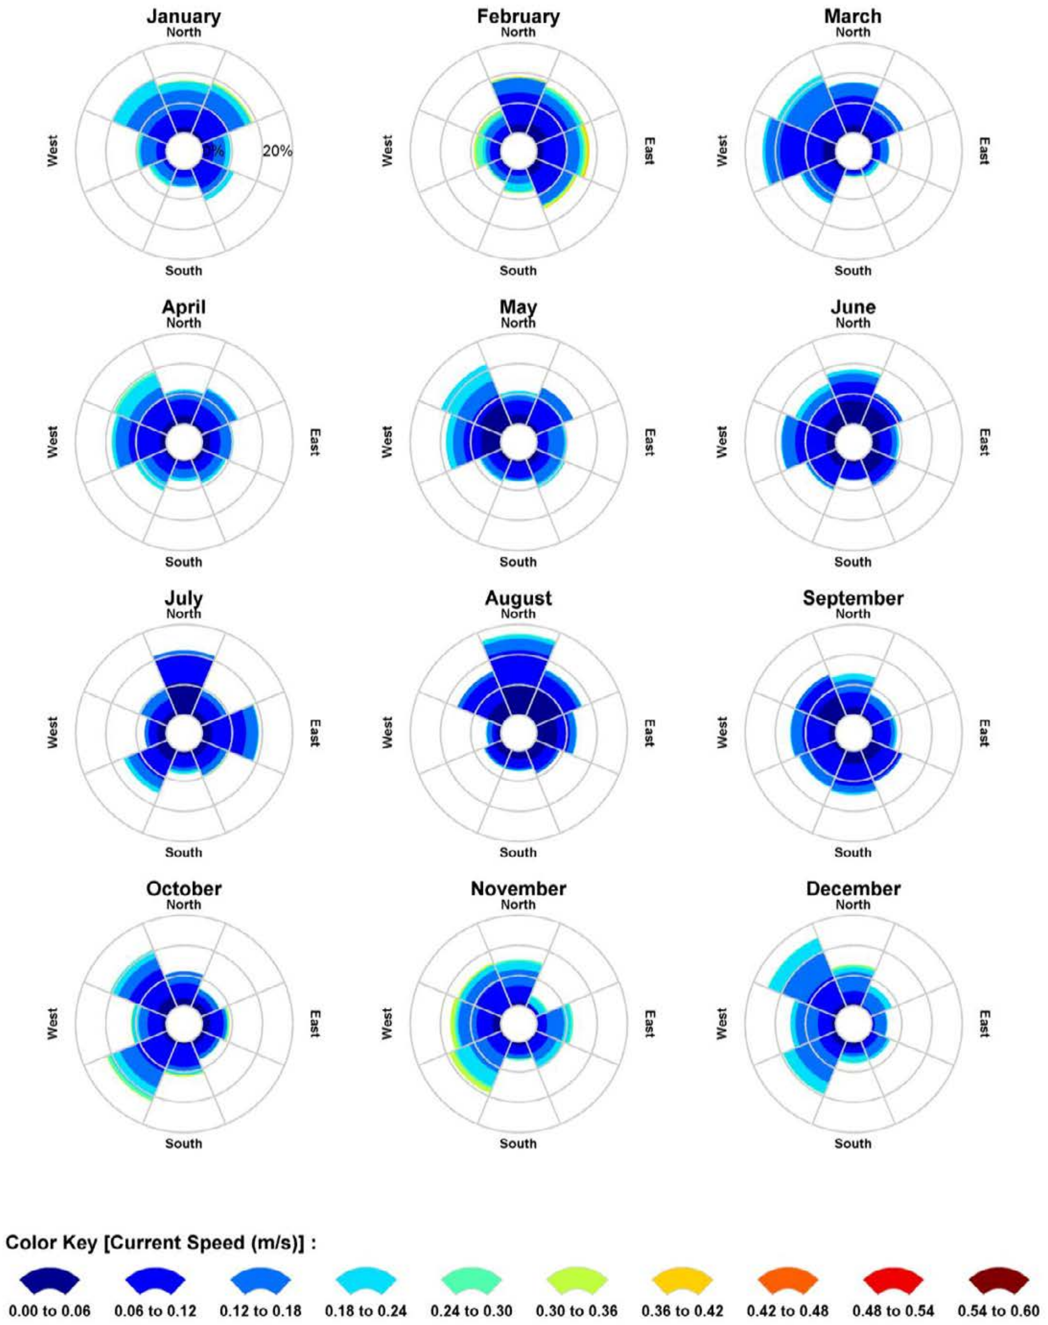

Figure 2.8 Monthly current distribution (2006-2015, inclusive) derived from the BRAN database near to the Scenario 1, 2 and 3 spill locations. The colour key shows the current magnitude, the compass direction provides the direction towards which the current is flowing, and the size of the wedge gives the percentage of the record.

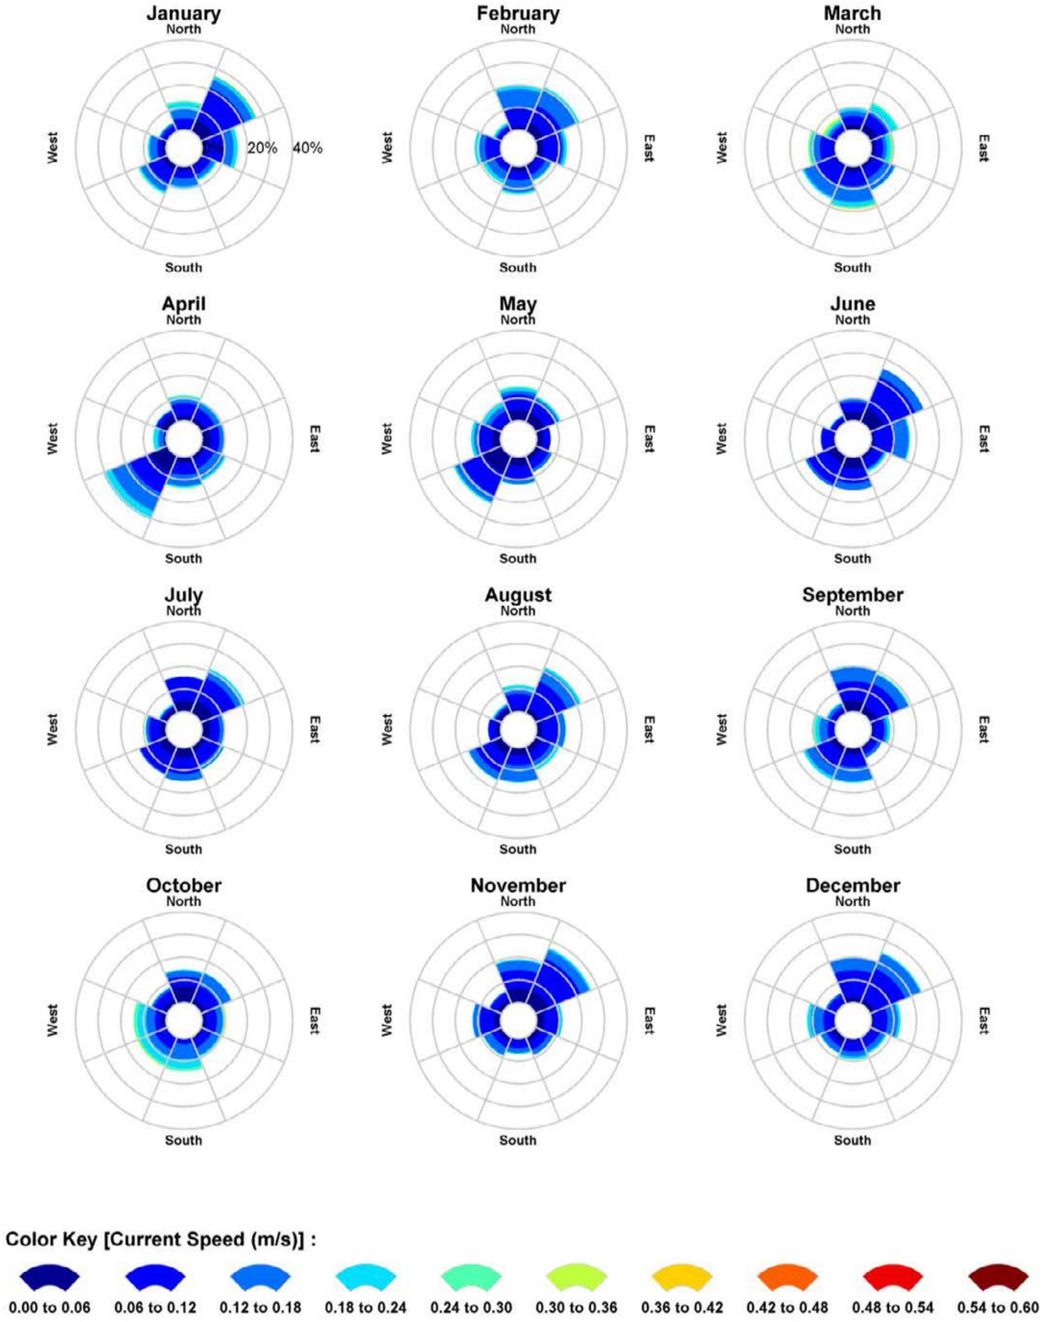

Figure 2.9 **Monthly current distribution (2006-2015, inclusive) derived from the BRAN database near to the Scenario 4 spill location. The colour key shows the current magnitude, the compass direction provides the direction towards which the current is flowing, and the size of the wedge gives the percentage of the record.**

2.3.1.3 Tidal Circulation

2.3.1.3.1 Description of Tidal Model: HYDROMAP

As the BRAN model does not include tidal forcing, and because the data is only available at a daily frequency, a tidal model was developed for the study region using RPS' three-dimensional hydrodynamic model, HYDROMAP.

The model formulations and output (current speed, direction and sea level) of this model have been validated through field measurements around the world for more than 30 years (Isaji & Spaulding, 1984, 1986; Isaji *et al.*, 2001; Zigic *et al.*, 2003). HYDROMAP current data has also been widely used as input to forecasts and hindcasts of oil spill migrations in Australian waters. This modelling system forms part of the National Marine Oil Spill Contingency Plan for the Australian Maritime Safety Authority (AMSA, 2002).

HYDROMAP simulates the flow of ocean currents within a model region due to forcing by astronomical tides, wind stress and bottom friction. The model employs a sophisticated dynamically nested-gridding strategy, supporting up to six levels of spatial resolution within a single domain. This allows for higher resolution of currents within areas of greater bathymetric and coastline complexity, or of particular interest to a study.

The numerical solution methodology of HYDROMAP follows that of Davies (1977a, 1977b) with further developments for model efficiency by Owen (1980) and Gordon (1982). A more detailed presentation of the model can be found in Isaji & Spaulding (1984).

2.3.1.3.2 Tidal Domain Setup

A HYDROMAP model was established over a domain that extended approximately 3,300 km east-west by 3,100 km north-south over the eastern Indian Ocean. The grid extends beyond Eucla in the south and beyond Bathurst Island in the north (Figure 2.10). Approximately 98,600 cells were used to define the region, with four layers of sub-gridding applied to provide variable resolution throughout the domain. The resolution at the primary level was 15 km. The finer levels were defined by subdividing these cells into 4, 16 and 64 cells, resulting in resolutions of 7.5 km, 3.75 km and 1.88 km.

The finer grids were allocated in a step-wise fashion to areas where higher resolution of circulation patterns was required to resolve flows through channels, around shorelines or over more complex bathymetry. Figure 2.11 shows a zoomed subset of the hydrodynamic model grid in the Scott Reef region, showing the finer resolution grids surrounding Scott Reef, the numerous shoals and islands, and complex areas of the mainland coastline.

Modelling of the tidal circulation at relatively fine scales in the topographically-complex area around Scott Reef was achieved using an additional model sub-domain with resolutions ranging down to <500 m. Major tidal channels that occur across the reef flats of North Scott Reef were represented in this model, with tidal current flows across the rest of the flats known to be minimal.

High-resolution (~50 m) bathymetric data covering Scott and Seringapatam Reefs and the Brecknock, Torosa and Calliance gas fields was supplied by Woodside. Beyond these areas, bathymetric data used to define the three-dimensional shape of the study domain was extracted from the Geoscience Australia 250 m resolution bathymetry database (GA, 2009) and the CMAP electronic chart database, supplemented where necessary with manual digitisation of chart data supplied by the Australian Hydrographic Office. Depths in the domain ranged from shallow intertidal areas through to approximately 7,200 m.

2.3.1.3.3 Tidal Boundary Conditions

Ocean boundary data for the HYDROMAP model was obtained from the TOPEX/Poseidon global tidal database (TPXO7.2) of satellite-measured altimetry data, which provided estimates of tidal amplitudes and phases for the eight dominant tidal constituents (designated as K_2, S_2, M_2, N_2, K_1, P_1, O_1 and Q_1) at a horizontal scale of approximately 0.25°. Using the tidal data, sea surface heights are firstly calculated along the open boundaries at each time step in the model.

The TOPEX/Poseidon satellite data is produced, and quality controlled by the US National Atmospheric and Space Agency (NASA). The satellites, equipped with two highly accurate altimeters capable of taking sea level measurements accurate to less than ±5 cm, measured oceanic surface elevations (and the resultant tides) for over 13 years (1992-2005). In total, these satellites carried out more than 62,000 orbits of the planet. The TOPEX/Poseidon tidal data has been widely used amongst the oceanographic community, being the subject of more than 2,100 research publications (e.g. Andersen, 1995; Ludicone *et al.*, 1998; Matsumoto *et al.*, 2000; Kostianoy *et al.*, 2003; Yaremchuk & Tangdong, 2004; Qiu & Chen, 2010). As such, the TOPEX/Poseidon tidal data is considered suitably accurate for this study.

2.3.1.3.4 Tidal Elevation Validation

For the purpose of verification of the tidal predictions, the model output was compared against independent predictions of tides using the XTide database (Flater, 1998). The XTide database contains harmonic tidal constituents derived from measured water level data at locations around the world. Overall, there are more than 120 tidal stations within the HYDROMAP model domain; however, some of these are located in areas that are not sufficiently resolved by this large-scale ocean model. More than 80 stations along the coastline were suitable for comparisons of the model performance with the observed data. These stations covered the mid-to-northwest regions of the Western Australian coastline, encompassing the locales of the marine discharges considered in this study (Figure 2.10 and Figure 2.11). For the purposes of brevity and clarity, a selected representative subset of the available tidal station validation data is presented here.

Water level time series for the selected subset of ten stations are shown in Figure 2.12 and Figure 2.13 for a one-month period (January 2018). All comparisons show that the model produces a very good match to the known tidal behaviour for a wide range of tidal amplitudes and clearly represents the varying diurnal and semi-diurnal nature of the tidal signal.

The model skill was further evaluated through a comparison of the predicted and observed tidal constituents, derived from an analysis of model-predicted time series at each of the tidal station locations. Scatter plots of the observed and modelled amplitude (top) and phase (bottom) of the five dominant tidal constituents (S_2, M_2, N_2, K_1 and O_1) for all relevant stations within the model domain (>80) are presented in Figure 2.14. The red line on each plot shows the 1:1 line, which would indicate a perfect match between the modelled and observed data. Note that the data is generally closely aligned to the 1:1 line demonstrating the high quality of the model performance.

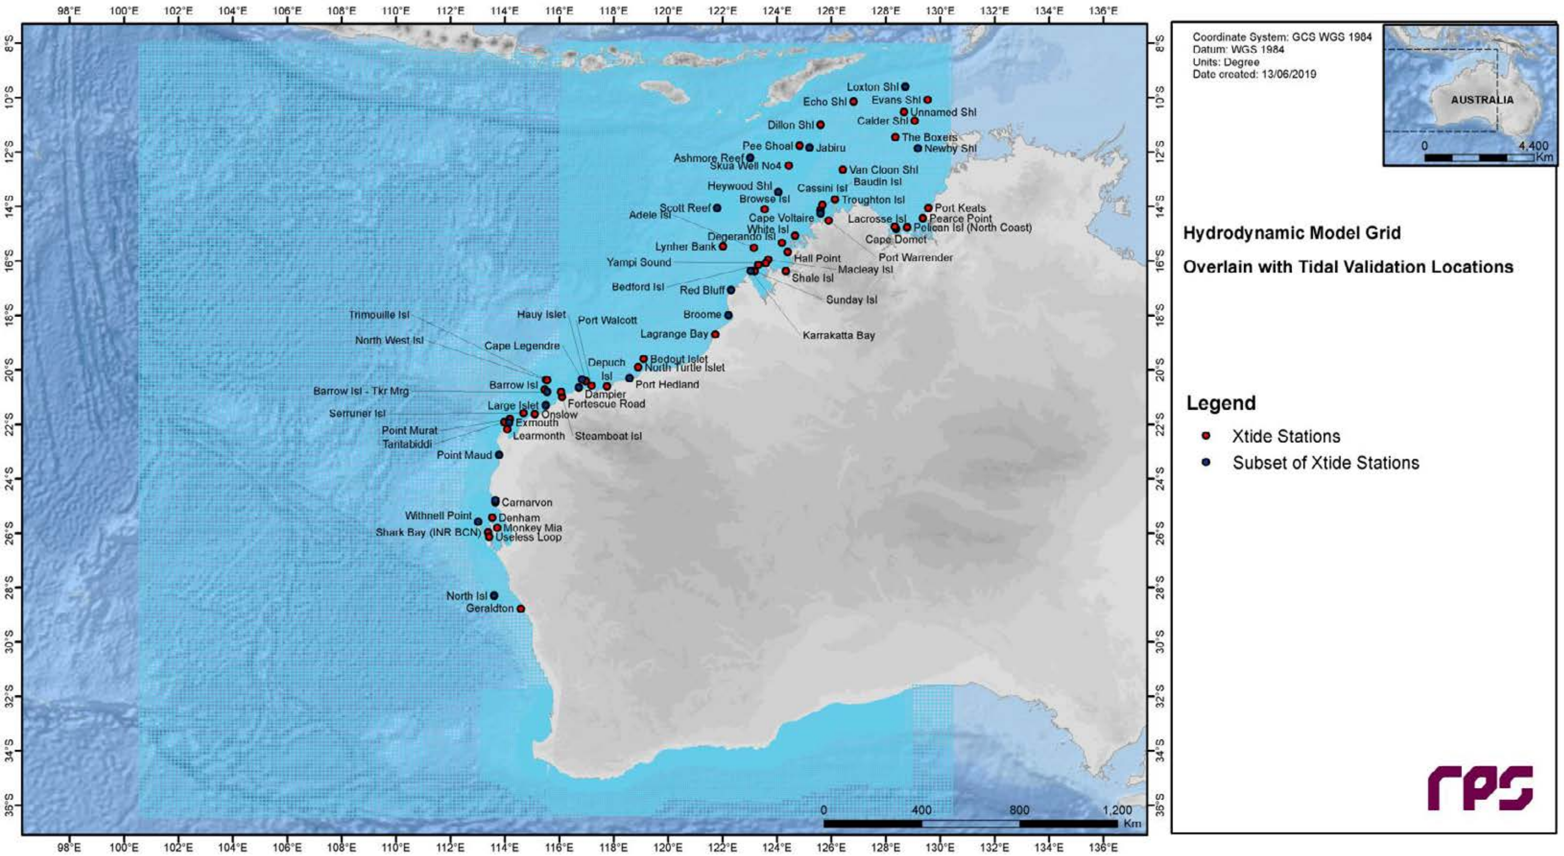

Figure 2.10 Hydrodynamic model grid (blue wire mesh) used to generate the tidal currents, showing the full domain in context with the continental land mass and the locations available for tidal comparisons (red and blue labelled dots). Higher-resolution areas are indicated by the denser mesh zones.

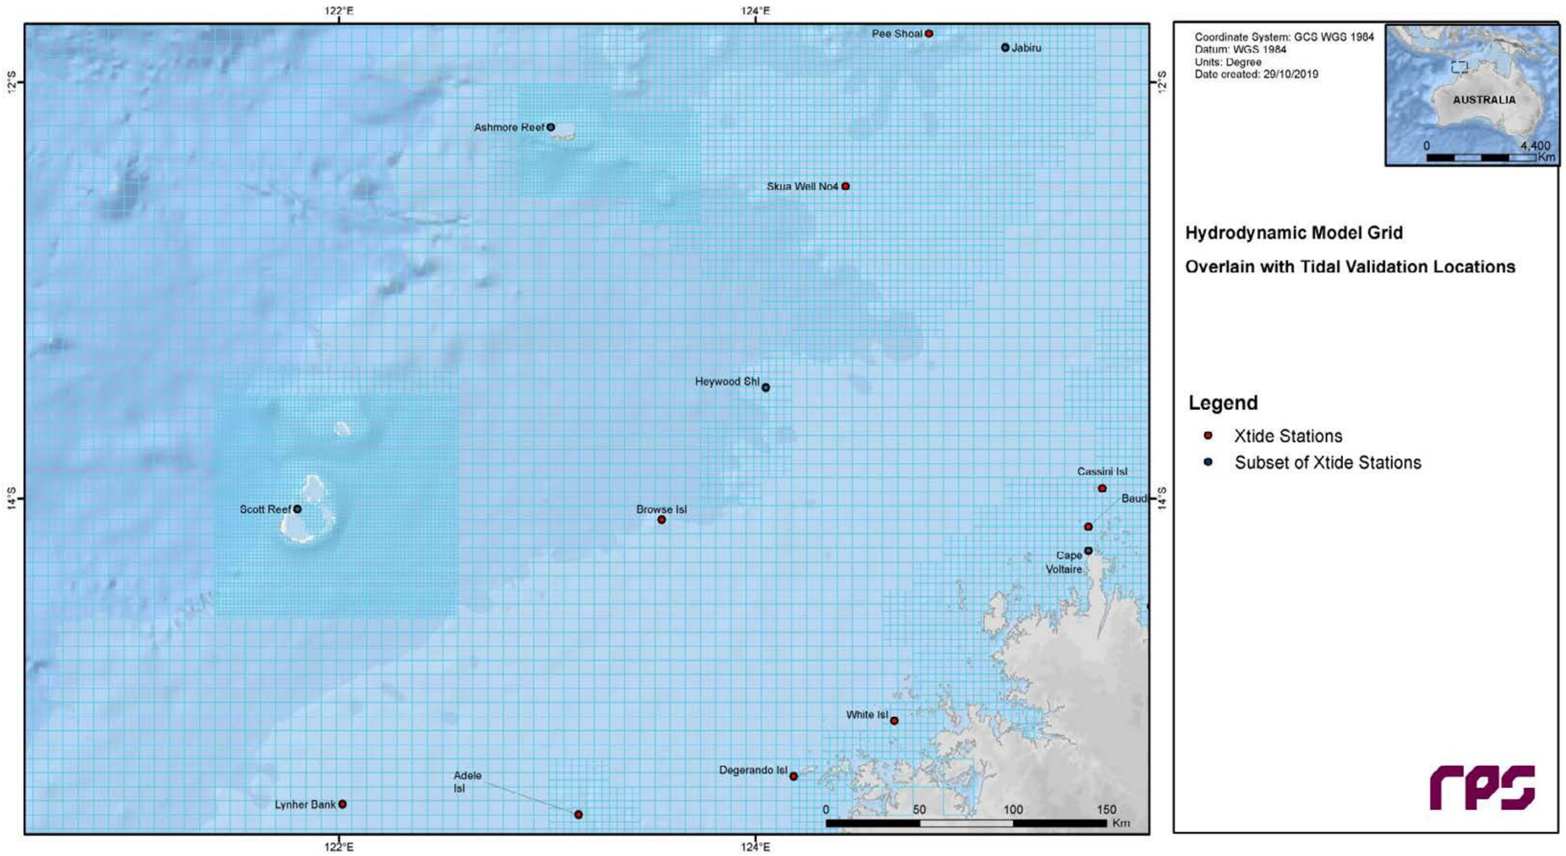

Figure 2.11 Zoomed subset of the hydrodynamic model grid (blue wire mesh) for the Scott Reef area, showing the locations available for tidal comparisons (red and blue labelled dots). Higher-resolution areas are indicated by the denser mesh zones.

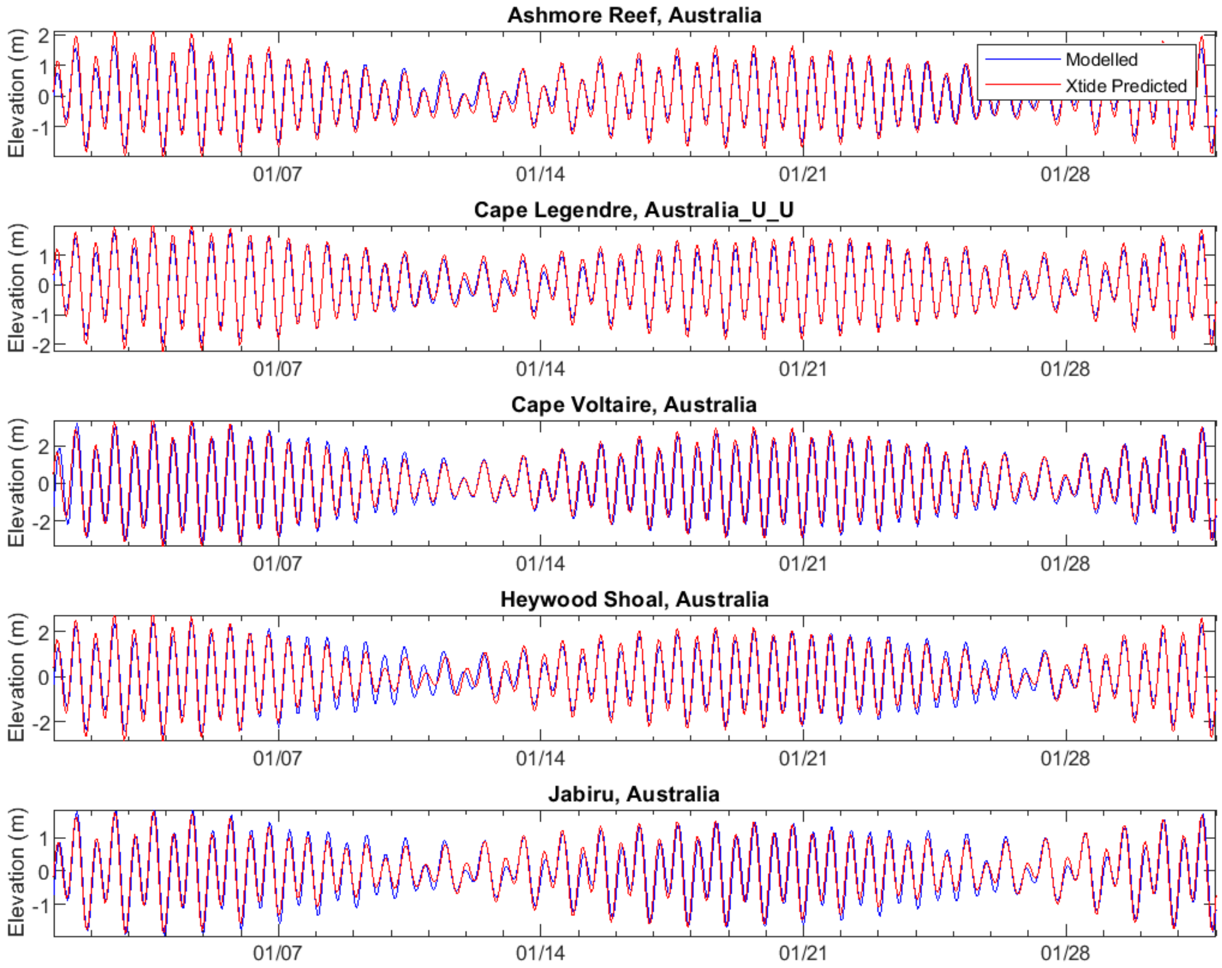

Figure 2.12 Comparisons between the predicted (blue line) and observed (red line) surface elevation variations at five locations in the north-east of the tidal model domain for January 2018.

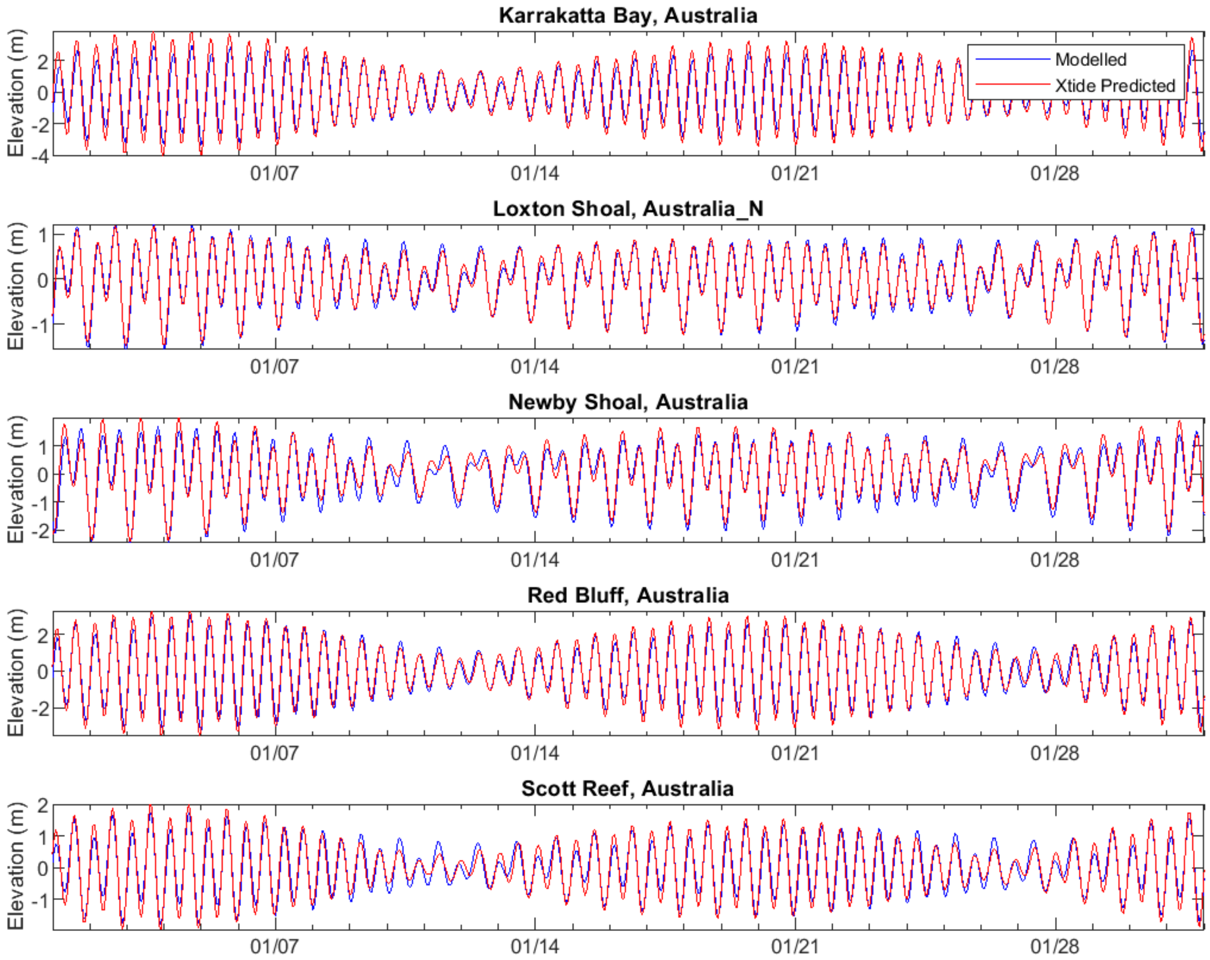

Figure 2.13 Comparisons between the predicted (blue line) and observed (red line) surface elevation variations at five locations in the north-east of the tidal model domain for January 2018.

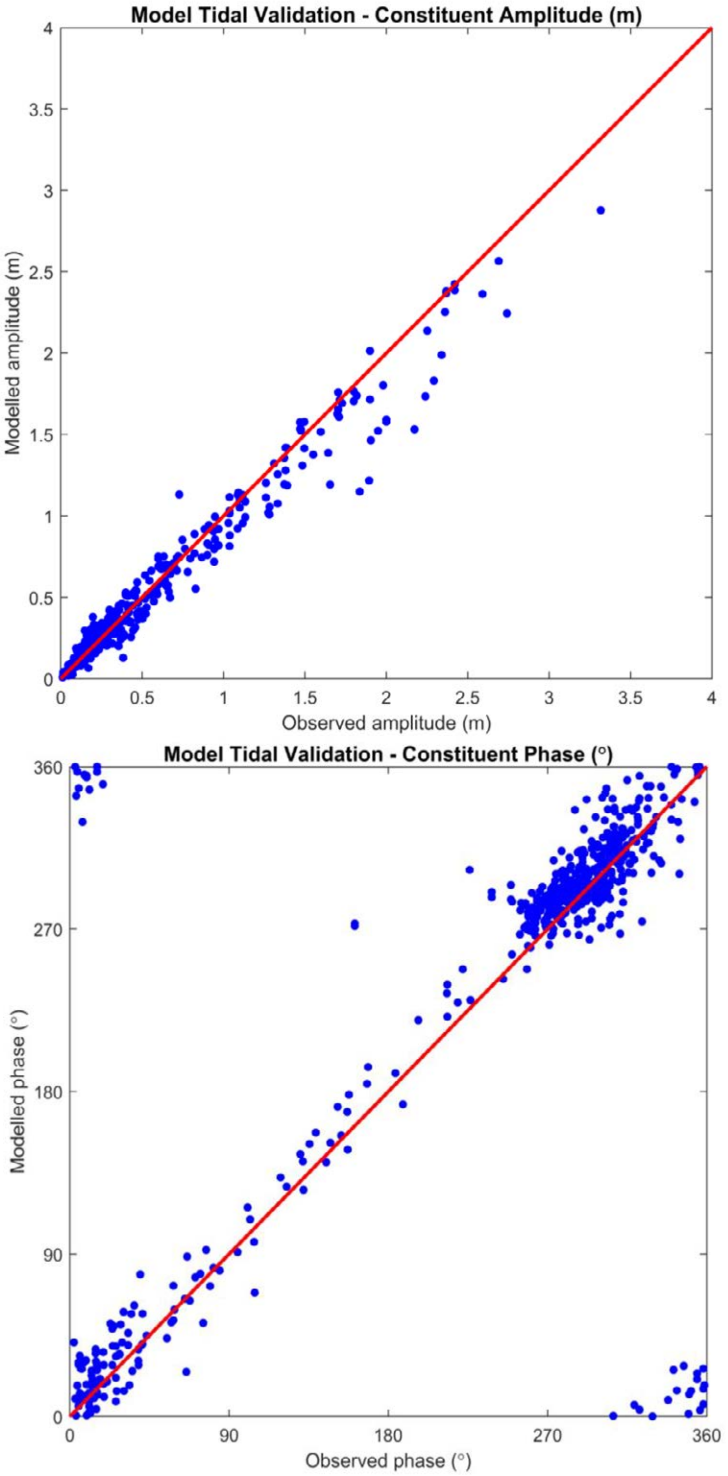

Figure 2.14 Comparisons between modelled and observed tidal constituent amplitudes (top) and phases (bottom) at all relevant stations (>80) in the HYDROMAP model domain. The red line indicates a 1:1 correlation between the modelled and observed data.

2.3.1.3.5 Tidal Currents at the Spill Locations

Figure 2.15 to Figure 2.17 show the monthly distributions of current speeds and directions for the HYDROMAP data points closest to the spill locations for Scenario 1, Scenarios 2 and 3, and Scenario 4, respectively. Note that the convention for defining current direction is the direction towards which the current flows.

The data indicates cyclical tidal flow directions along a northwest-southeast axis at the Scenario 2 to 4 sites, and along a north-south axis at the Scenario 1 site which is relatively close to Scott Reef and experiences steering of the tidal flow direction around the reef. Maximum speeds at the Scenario 1 to 3 sites are approximately 0.25-0.3 m/s, with peak speeds at the Scenario 4 site being around 0.4 m/s.

The extracted current data near the spill locations provides an insight into the expected initial behaviour of any released oil due to the tidal currents alone. Oil moving beyond the release sites, particularly towards the coast, would be subject to considerable variation in the tidal current regime.

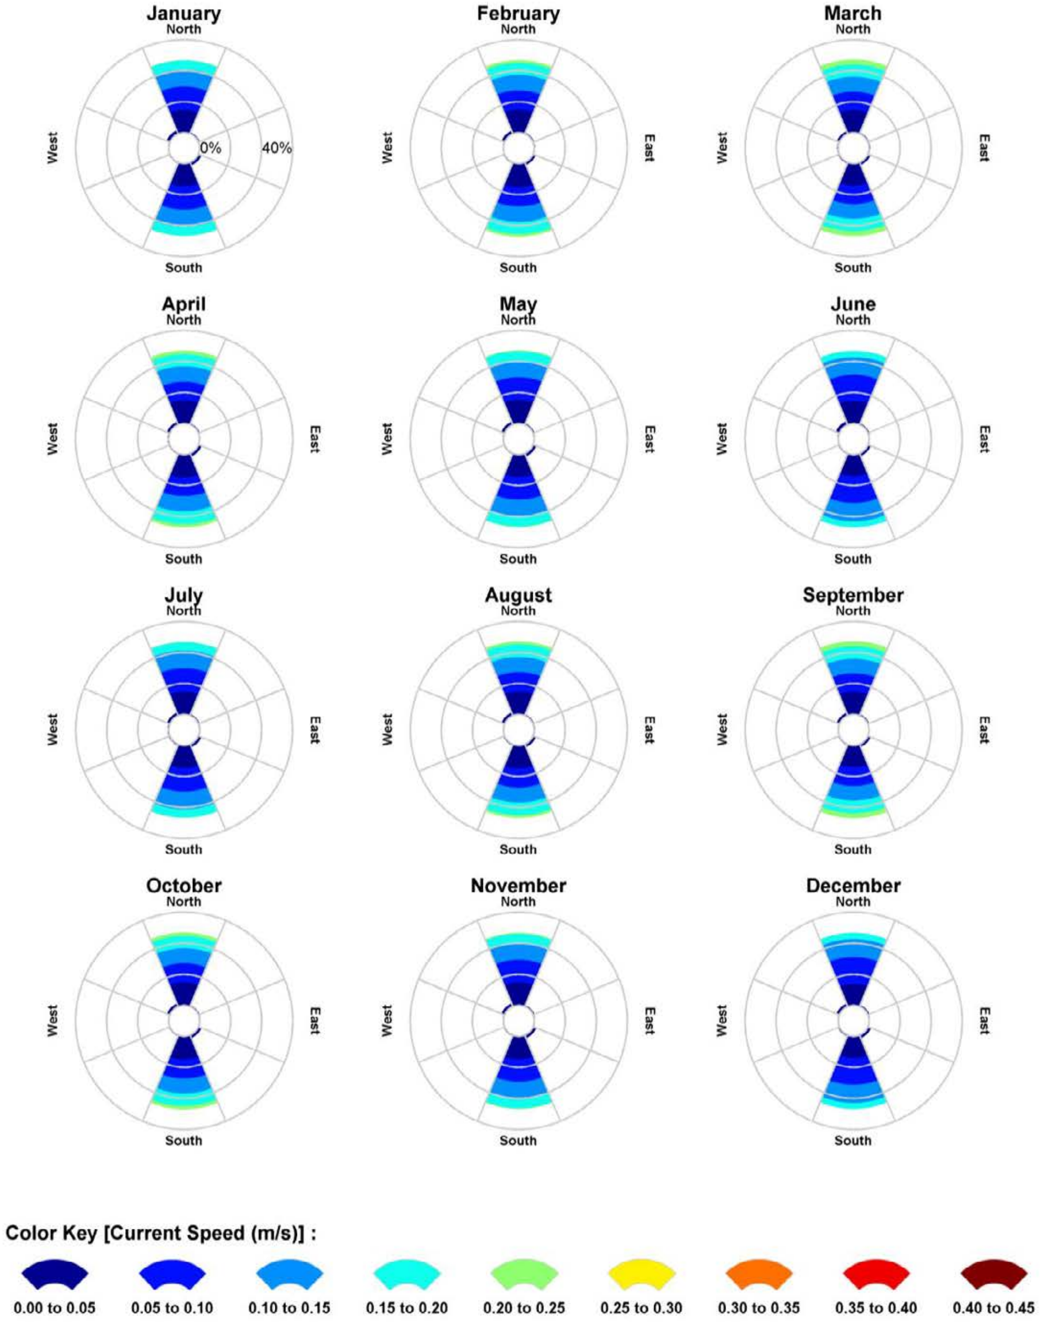

Figure 2.15 Monthly current distribution (2006-2015, inclusive) derived from the HYDROMAP database near to the Scenario 1 spill location. The colour key shows the current magnitude, the compass direction provides the direction towards which the current is flowing, and the size of the wedge gives the percentage of the record.

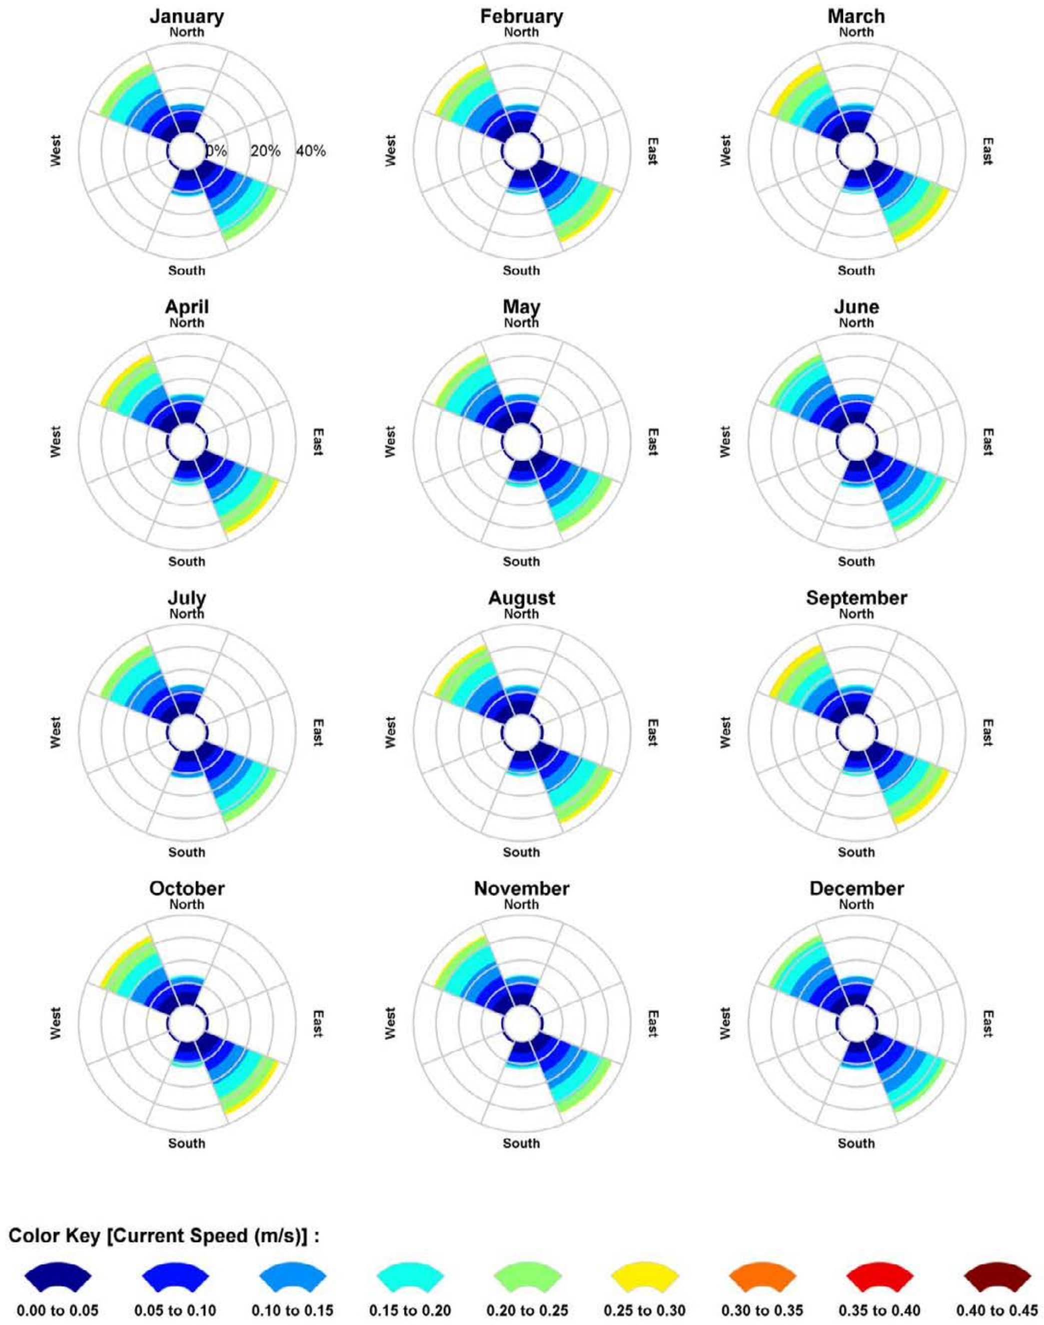

Figure 2.16 Monthly current distribution (2006-2015, inclusive) derived from the HYDROMAP database near to the Scenario 2 and 3 spill locations. The colour key shows the current magnitude, the compass direction provides the direction towards which the current is flowing, and the size of the wedge gives the percentage of the record.

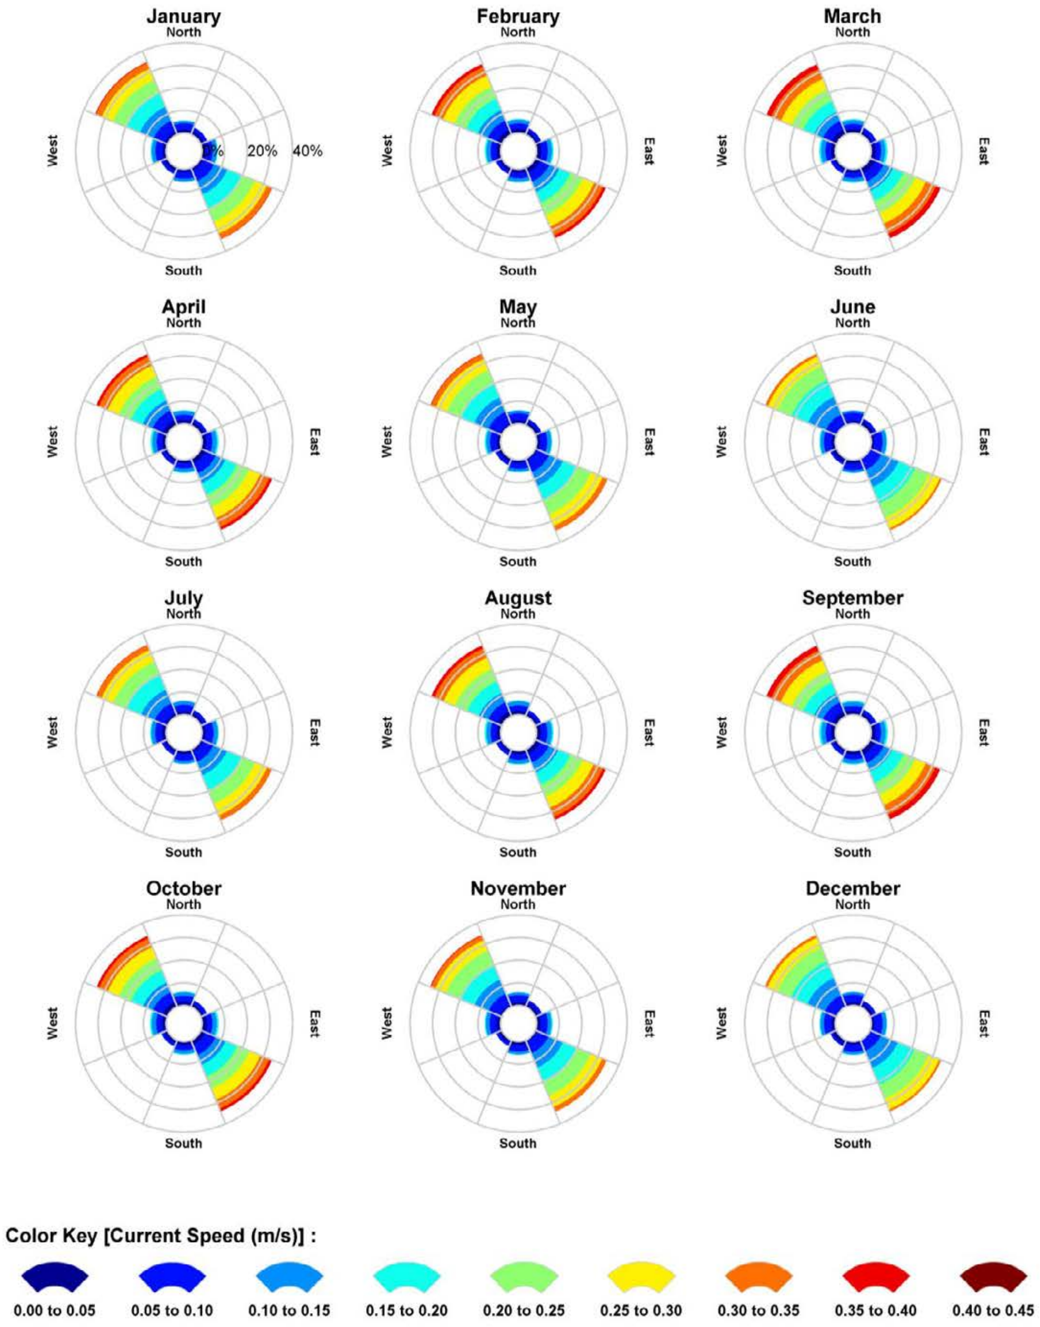

Figure 2.17 Monthly current distribution (2006-2015, inclusive) derived from the HYDROMAP database near to the Scenario 4 spill location. The colour key shows the current magnitude, the compass direction provides the direction towards which the current is flowing, and the size of the wedge gives the percentage of the record.

2.3.2 Wind Data

To account for the influence of the wind on surface-bound oil slicks, representation of the wind conditions was provided by spatial wind fields sourced from the National Center for Environmental Prediction (NCEP), via the National Oceanic and Atmospheric Administration (NOAA) and Cooperative Institute for Research in Environmental Sciences (CIRES) Climate Diagnostics Center (CDC). The NCEP Climate Forecast System Reanalysis (CFSR; Saha *et al.*, 2010) is a fully-coupled, data-assimilative hindcast model representing the interaction between the Earth's oceans, land and atmosphere. The gridded data output, including surface winds, is available at 0.25° resolution and 1-hourly time intervals.

Time series of wind speed and direction were extracted from the CFSR database for all nodes in the model domain for the same temporal coverage as the current data (2006-2015, inclusive). The data was assumed to be a suitably representative sample of the wind conditions over the study area for future years.

Figure 2.18 and Figure 2.19 show the monthly distributions of wind speeds and directions for the CFSR data points closest to the spill locations for Scenarios 1 to 3 and Scenario 4, respectively. Note that the convention for defining wind direction is the direction from which the wind blows.

The wind data indicates predominantly easterly directions between May and July at the Scenario 1 to 3 spill sites, and westerly/south-westerly directions dominating in the October to February period. At the Scenario 4 spill site, easterly/south-easterly directions are most common between April and August, with southerly and westerly directions most prominent between September and March. Average wind speeds across the year near all spill sites vary in the range 5.9-6.5 m/s, with year-round maximum speeds of 25.5-29.4 m/s.

The extracted wind data near the spill location suggests possible initial trajectories due to the wind acting on surface slicks in the absence of any current effects. Note that the actual trajectories of surface slicks will be the net result of a combination of the prevailing wind and current vectors acting at a given time and location.

Figure 2.18 Monthly wind distribution (2006-2015, inclusive) derived from the CFSR database near to the Scenario 1, 2 and 3 spill locations. The colour key shows the wind magnitude, the compass direction provides the direction from which the wind is blowing, and the size of the wedge gives the percentage of the record.

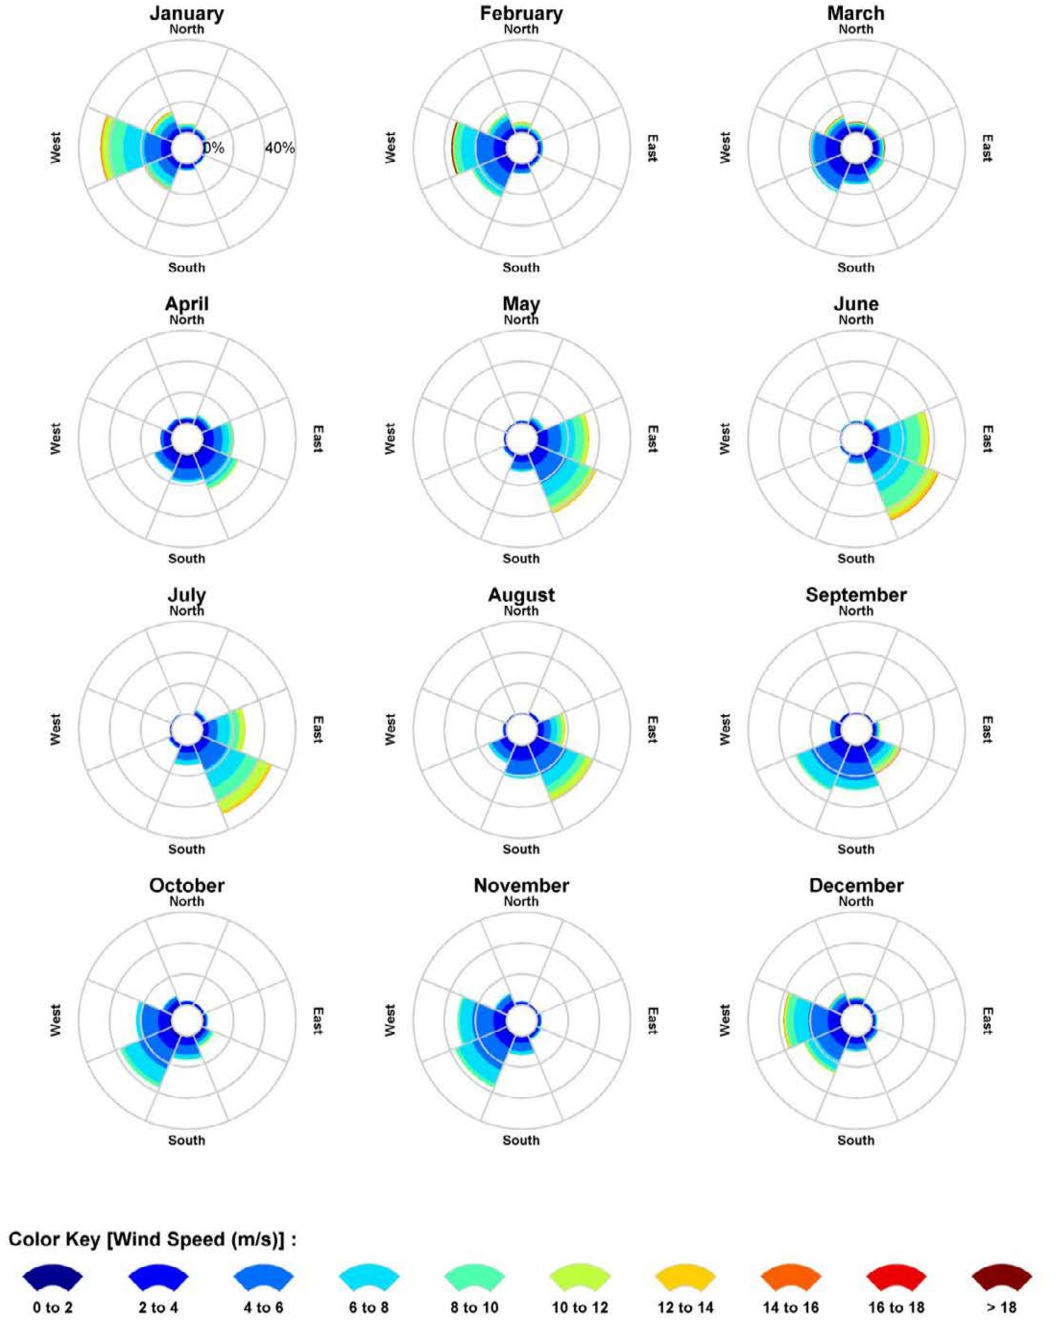

Figure 2.19 Monthly wind distribution (2006-2015, inclusive) derived from the CFSR database near to the Scenario 4 spill location. The colour key shows the wind magnitude, the compass direction provides the direction from which the wind is blowing, and the size of the wedge gives the percentage of the record.

2.3.3 Water Temperature and Salinity Data

The World Ocean Atlas 2013 (WOA13) is provided by NOAA and is a hindcast model of the climatological fields of in situ temperature, salinity, and a number of additional variables (NOAA, 2013a). WOA13 has a 0.25° resolution and has standard depth levels ranging from the water surface to 5,500 m (Locarnini *et al.*, 2013; Zweng *et al.*, 2013). Vertical profiles of sea temperature and salinity at the spill locations were retrieved from a data point in the WOA13 database near the Torosa FPSO location (13° 52' 30" S, 121° 52' 30" E), with monthly averages used as input to both SIMAP and OILMAP.

Figure 2.20 shows the variation in water temperature and salinity both seasonally and over depth. During the period from May to September, surface mixing is evident over the upper 50-100 m of the water column (where the depth is approximately 300 m at this location). In contrast, during the period from October to April, the surface mixed layer is shallower, indicating stronger thermal stratification. The average temperature over the upper 300 m of the water column varies between approximately 10-30 °C across the year, while the average salinity over this depth range varies between approximately 33.8-34.8 PSU year-round.

2.3.4 Dispersion

A horizontal dispersion coefficient of 10 m^2/s was used to account for dispersive processes acting at the surface that are below the scale of resolution of the input current field, based on typical values for coastal waters (Okubo, 1971). Dispersion rates within the water column (applicable for entrained and dissolved plumes of hydrocarbons) were specified at 1 m^2/s, based on empirical data for the dispersion of hydrocarbon plumes over the North West Shelf (King & McAllister, 1998).

2.3.5 Replication

Multiple replicate simulations were completed for the defined scenarios to account for trends and variations in the trajectory and weathering of spilled oil, with an even number of replicates completed using samples of metocean data that commenced within each month. For Scenario 1, a total of 100 replicate simulations were run over an annual period; for Scenarios 2-4, a total of 200 replicate simulations were run over an annual period.

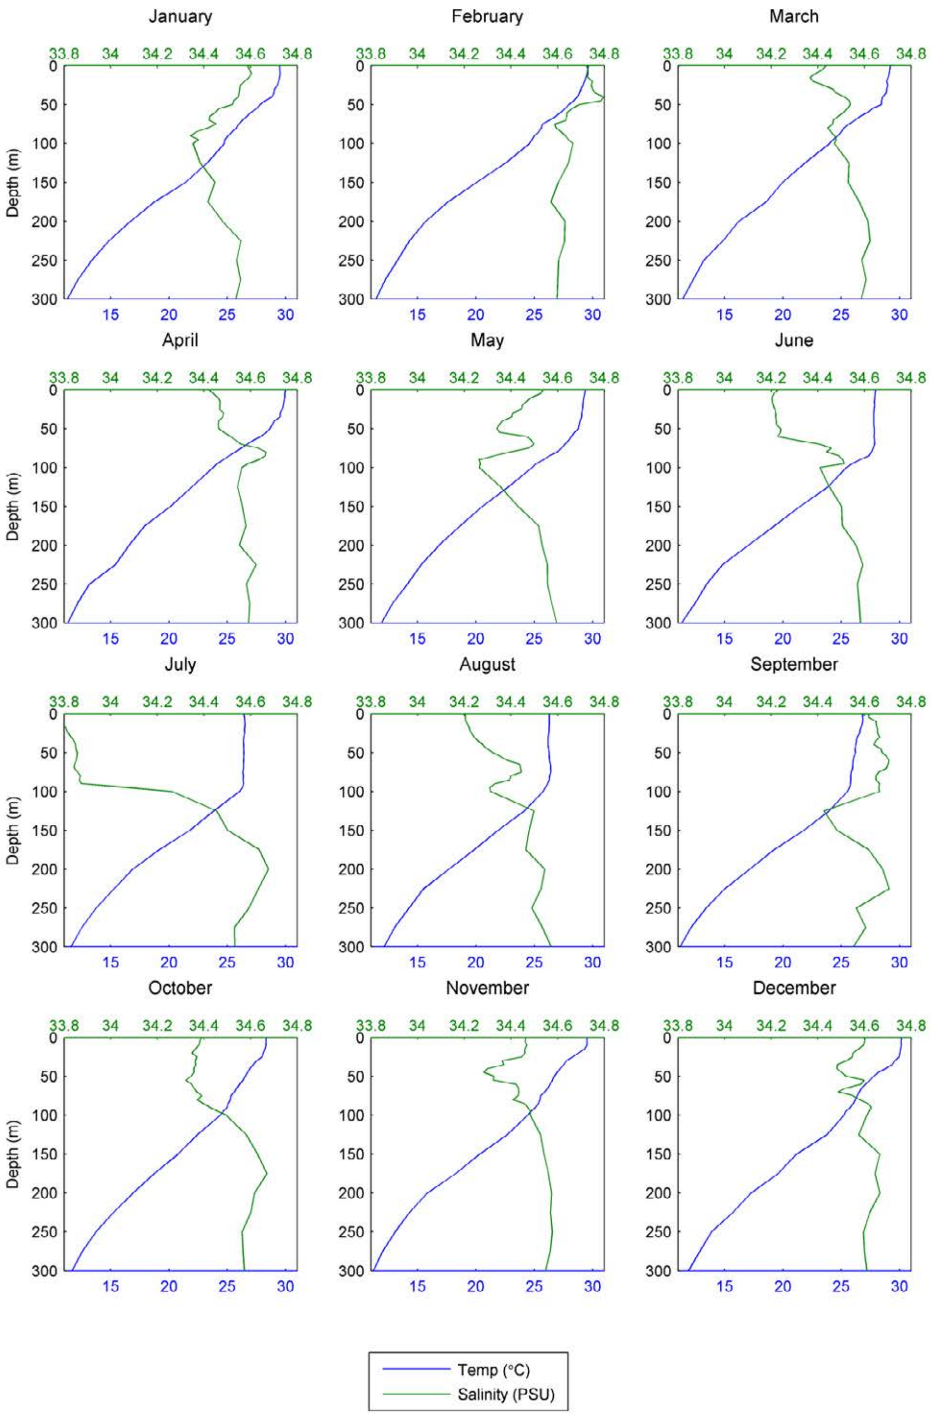

Figure 2.20 Temperature (blue line) and salinity (green line) profiles derived from the WOA13 database near the Torosa FPSO location (13° 52' 30" S, 121° 52' 30" E). Depth of 0 m is the water surface.

2.3.6 Contact Thresholds

2.3.6.1 Overview

The SIMAP model will track oil concentrations to very low levels. Hence, it is useful to define meaningful threshold concentrations for the recording of contact by oil components and determining the probability of exposure at a location (calculated from the number of replicate simulations in which this contact occurred).

The judgement of meaningful levels is complicated and will depend upon the mode of action, sensitivity of the biota contacted, the duration of the contact and the particular toxicity of the compounds that are represented in the oil. The latter factor is further complicated by the change in the composition of an oil type over time due to weathering processes. Without specific testing of the oil types, at different states of weathering against a wide range of the potential local receptors, such considerations are beyond the scope of this investigation.

For this case, thresholds for floating, entrained and dissolved aromatic hydrocarbons were specified by Woodside for use in defining the potential zone of influence of the spill event. These thresholds are summarised in Table 2.2 and discussed afterwards.

Table 2.2 Summary of the thresholds applied in this study.

Floating Oil Concentration (g/m^2)	Shoreline Oil Concentration (g/m^2)	Entrained Oil Concentration (ppb)	Dissolved Aromatic Hydrocarbon Concentration (ppb)
1 10	100	100 (Scenarios 1-3) 500 (Scenario 4)	50 (Scenarios 1-3) 500 (Scenario 4)

2.3.6.2 Floating Oil

Floating oil concentrations are relevant to describing the risks of oil coating emergent reefs, vegetation in the littoral zone and shoreline habitats, as well as the risk to wildlife found on the water surface, such as marine mammals, reptiles and birds.

Estimates for the minimal thickness of floating oil that might result in harm to seabirds through ingestion from preening of contaminated feathers, or the loss of the thermal protection of their feathers, has been estimated by different researchers at approximately 10 g/m^2 (French-McCay, 2009) to 25 g/m^2 (Scholten *et al.*, 1996; Koops *et al.*, 2004). Hence, the 10 g/m^2 threshold is likely to be moderately conservative in terms of environmental harm for effects on seabirds, for example. The lower threshold of 1 g/m^2 is likely to be an indicator of where there is a visual presence of an oil slick that may trigger social and economic impacts but where there is little potential for environmental impact.

It is important to note that real spill events generate surface slicks that break up into multiple patches separated by areas of open water. Concentrations calculated and presented in this study represent necessary areal averaging over discrete model cells, and therefore indicate the potential for both higher and lower relative concentrations in the surrounding space.

2.3.6.3 Shoreline Oil

Shoreline oil concentrations are relevant to describing the risks of oil contact/stranding on shorelines and beaches. French *et al.* (1996) and French-McCay (2009) have defined an oil exposure threshold of 100 g/m^2 for shorebirds and wildlife (furbearing aquatic mammals and marine reptiles) on or along the shore, which is based on studies for sub-lethal and lethal impacts. The 100 g/m^2 threshold has been used in previous environmental risk assessment studies (French-McCay *et al.*, 2004, 2011, 2012; French-McCay, 2003; NOAA, 2013b). This threshold is also recommended in the Australian Maritime Safety Authority's foreshore assessment guide as the acceptable minimum thickness that does not inhibit the potential for recovery and is best remediated by natural coastal processes alone (AMSA, 2015).

2.3.6.4 Entrained Oil

Oil can be entrained into the water column from surface slicks due to wind and wave-induced turbulence, or be generated subsea by a pressurised discharge at depth. Entrained oil presents a number of possible mechanisms for exerting exposure. The entrained oil droplets may contain soluble compounds and hence have the potential to generate elevated concentrations of dissolved hydrocarbons (e.g. if mixed by breaking waves against a shoreline). Physical and chemical effects of the entrained oil droplets have also been demonstrated through direct contact with organisms; for example, through physical coating of gills and body surfaces, or accidental ingestion (NRC, 2005).

A review of the concentrations of physically entrained oil that has been demonstrated to have harmful effects in laboratory studies (NRC, 2005) showed wide variation depending on the test organisms and the initial oil mixture. For mortality of molluscs, reported LC_{50} values range from 500 ppb to 2,000 ppb with 96-hour exposure. Wider exposure sensitivities are displayed by species of crustaceans (100 ppb to 258,000 ppm) with 96-hour exposure, while marine fish larvae appear yet more sensitive with LC_{50} values as low as 45 ppb after 24-hour exposure.

As indicators of potential exposure, thresholds for concentrations of entrained oil were defined at 100 ppb and 500 ppb. These thresholds are particularly relevant for short duration (acute) exposure to organisms or fixed habitats affected by the dynamically-varying oil plume.

2.3.6.5 Dissolved Aromatic Hydrocarbons

The mode of action of soluble hydrocarbons is a narcotic effect resulting from uptake into the tissues of organisms. This effect is additive, increasing with exposure concentration or with time of exposure (French, 2000; NRC, 2005) For many oil mixtures, the concentration of aromatic hydrocarbons, and specifically the polyaromatic hydrocarbons (PAHs), in the water-soluble fraction is the best predictor of the toxicity of the oil.

As indicators of potential exposure, thresholds for concentrations of dissolved aromatic hydrocarbons were defined at 50 ppb and 500 ppb. Because exposure times may be short (<1-2 hours) in the case of a slick passing over a fixed habitat (such as a reef), due to fluctuations in the plume location with changing environmental conditions, and because marine organisms can typically tolerate concentrations of toxic hydrocarbons that are two or more orders of magnitude higher over such short durations (Pace *et al.*, 1995; French, 2000), these thresholds are likely to be indicative of potentially harmful exposure to fixed habitats over short exposure durations.

2.3.7 Oil Characteristics

2.3.7.1 Overview

Characteristics of unstabilised Torosa Condensate (pre-processed condensate) and stabilised Torosa Condensate (condensate which has been processed by the FPSO) were specified from data supplied by Woodside (Woodside, 2019), and are summarised alongside characteristics for marine diesel in Table 2.3.

For Scenario 1, a different unstabilised Torosa Condensate mixture was specified for the sea-surface and subsea release phases. The formulation used in the sea-surface release phase is referred to as unstabilised Torosa Condensate (surface). The formulation used in the subsea release phase is referred to as unstabilised Torosa Condensate (subsea).

Table 2.3 Characteristics of the oil types used in the modelling of Scenarios 1-4.

Oil Type	Density (g/cm^3)	Viscosity (cP)	Component	Volatile (%)	Semi-Volatile (%)	Low Volatility (%)	Residual (%)	Aromatics (%)
			Boiling point (°C)	**<180 C4 to C10**	**180 - 265 C11 to C15**	**265 - 380 C16 to C20**	**>380 >C20**	**Of whole oil <380 BP**
Unstabilised Torosa Condensate (subsea)	0.780 at 25 °C	1.092 at 20 °C	**% of total**	14.5	39.9	20.7	24.9	26.2
			% aromatics	2.5	8.8	14.9	-	-
Unstabilised Torosa Condensate (surface)	0.813 at 25 °C	2.519 at 25 °C	**% of total**	1.0	15.5	32.8	50.7	26.9
			% aromatics	0.2	3.1	23.6	-	-
Stabilised Torosa Condensate	0.780 at 20 °C	1.092 at 20 °C	**% of total**	57.0	21.0	8.0	14.0	19.6
			% aromatics	10.3	4.3	5.0	-	-
Marine Diesel	0.829 at 25 °C	4.000 at 25 °C	**% of total**	6.0	34.6	54.4	5.0	3.0
			% aromatics	1.8	1.0	0.2	-	-

The boiling points are dictated by the length of the carbon chains, with the longer and more complex compounds having a higher boiling point, and therefore lower volatility and evaporation rate.

The aromatic components within the volatile to low-volatility range are also soluble (with decreasing solubility following decreasing volatility) and will dissolve across the oil-water interface. The rate of dissolution will increase with increase in surface area. Hence, dissolution rates will be higher under discharge conditions that generate smaller oil droplets.

Atmospheric weathering will commence if and when oil droplets float to the water surface. Typical evaporation times once the hydrocarbons reach the surface and are exposed to the atmosphere are:

- Up to 12 hours for the C4 to C10 compounds (or less than 180 °C BP);
- Up to 24 hours for the C11 to C15 compounds (180-265 °C BP);
- Several days for the C16 to C20 compounds (265-380 °C BP); and
- Not applicable for the residual compounds (BP > 380 °C), which will resist evaporation, persist in the marine environment for longer periods, and be subject to relatively slow degradation.

The actual fate of released oil in the marine environment will depend greatly on the amount of oil that reaches the surface, either through the initial release or by rising after discharge in the water column.

2.3.7.2 Unstabilised Torosa Condensate (Surface/Subsea)

Two formulations of unstabilised Torosa Condensate (pre-processed condensate) were used in Scenario 1. Unstabilised Torosa Condensate (surface) contains a high proportion (50.7% by mass) of hydrocarbon compounds that will not evaporate at atmospheric temperatures; this proportion is lower but still significant (24.9%) for unstabilised Torosa Condensate (subsea). These compounds will persist in the marine environment.

The unweathered mixtures of unstabilised Torosa Condensate (surface) and unstabilised Torosa Condensate (subsea) have dynamic viscosities of 0.81 cP and 0.78 cP, respectively. The pour point of the whole oils (<15 °C) ensures that they will remain in a liquid state over the annual temperature range observed in the Timor Sea.

The mixtures are composed of hydrocarbons that have a wide range of boiling points and volatilities at atmospheric temperatures, and which will begin to evaporate at different rates on exposure to the atmosphere. Evaporation rates will increase with temperature, but in general about 1.0% of the unstabilised Torosa Condensate (surface) mass has the capacity to evaporate within the first 12 hours (BP < 180 °C); a further 15.5% could evaporate within the first 24 hours (180 °C < BP < 265 °C); and a further 32.8% could evaporate over several days (265 °C < BP < 380 °C). For unstabilised Torosa Condensate (subsea), 14.5% of the mass has the capacity to evaporate within the first 12 hours (BP < 180 °C); a further 39.9% could evaporate within the first 24 hours (180 °C < BP < 265 °C); and a further 20.7% could evaporate over several days (265 °C < BP < 380 °C).

Selective evaporation of the lower boiling-point components will lead to a shift in the physical properties of the remaining mixtures, including an increase in the viscosity and pour point. Although removal of the volatile compounds through evaporation and dissolution will result in an increase in density of the remaining oil, the mixtures are unlikely to solidify or sink as they weather.

The whole oils have low asphaltene content (0.66%), indicating a low propensity for the mixtures to take up water to form water-in-oil emulsion over the weathering cycle.

Soluble aromatic hydrocarbons contribute approximately 26.9% and 26.2% by mass of the unstabilised Torosa Condensate (surface) and unstabilised Torosa Condensate (subsea) oils, respectively. Each oil contains a significant proportion (surface, 23.6%; subsea, 14.9%) in the C16-C20 range of hydrocarbons; these compounds will evaporate slowly, resulting in the potential for dissolution of a proportion of them into the water.

2.3.7.3 Stabilised Torosa Condensate

Stabilised Torosa Condensate (condensate which has been processed by the FPSO) was used in Scenarios 2 and 3. Stabilised Torosa Condensate contains a moderate proportion (14.0% by mass) of hydrocarbon compounds that will not evaporate at atmospheric temperatures. These compounds will persist in the marine environment.

The unweathered mixture has a dynamic viscosity of 0.78 cP. The pour point of the whole oil (<15 °C) ensures that it will remain in a liquid state over the annual temperature range observed in the Timor Sea.

The mixture is composed of hydrocarbons that have a wide range of boiling points and volatilities at atmospheric temperatures, and which will begin to evaporate at different rates on exposure to the atmosphere. Evaporation rates will increase with temperature, but in general about 57.0% of the stabilised Torosa Condensate mass has the capacity to evaporate within the first 12 hours (BP < 180 °C); a further 21.0% could evaporate within the first 24 hours (180 °C < BP < 265 °C); and a further 8.0% could evaporate over several days (265 °C < BP < 380 °C).

Selective evaporation of the lower boiling-point components will lead to a shift in the physical properties of the remaining mixture, including an increase in the viscosity and pour point. Although removal of the volatile compounds through evaporation and dissolution will result in an increase in density of the remaining oil, the mixture is unlikely to solidify or sink as it weathers.

The whole oil has low asphaltene content (0.66%), indicating a low propensity for the mixture to take up water to form water-in-oil emulsion over the weathering cycle.

Soluble aromatic hydrocarbons contribute approximately 19.6% by mass of the whole oil, with a significant proportion (10.3%) in the C4-C10 range of hydrocarbons. These compounds will evaporate rapidly, reducing the potential for dissolution of a proportion of them into the water.

2.3.7.4 Marine Diesel

Marine diesel was used in Scenario 4. Marine diesel is a mixture of volatile and persistent hydrocarbons with low proportions of highly volatile and residual components. In general, about 6% of the oil mass should evaporate within the first 12 hours (BP < 180 °C); a further 35% should evaporate within the first 24 hours (180 °C < BP < 265 °C); and a further 54% should evaporate over several days (265 °C < BP < 380 °C). Approximately 5% of the oil is shown to be persistent. The aromatic content of the oil is approximately 3%.

If released in the marine environment and in contact with the atmosphere (i.e. surface spill), approximately 41% by mass of this oil is predicted to evaporate over the first couple of days depending upon the prevailing conditions, with further evaporation slowing over time. The heavier (low volatility) components of the oil have a tendency to entrain into the upper water column due to wind-generated waves, but can subsequently resurface if wind-waves abate. Therefore, the heavier components of this oil can remain entrained or on the sea surface for an extended period, with associated potential for dissolution of the soluble aromatic fraction.

2.3.8 Weathering Characteristics

2.3.8.1 Overview

A series of model weather tests were conducted to illustrate the potential behaviour of unstabilised Torosa Condensate (surface and subsea), stabilised Torosa Condensate and marine diesel when exposed to idealised and representative environmental conditions:

- Instantaneous release (1-hour discharge) onto the water surface at a discharge rate of 50 m^3/hr under calm wind conditions (constant 5 knots), assuming low seasonal water temperature (27 °C) and average air temperature (25 °C). Slick also subject to ambient tidal and drift currents.
- Instantaneous release (1-hour discharge) onto the water surface at a discharge rate of 50 m^3/hr under variable wind conditions (4-19 knots, drawn from representative data files), assuming low seasonal water temperature (27 °C) and average air temperature (25 °C). Slick also subject to ambient tidal and drift currents.

The first case is indicative of cumulative weathering rates under calm conditions that would not generate entrainment, while the second case may represent conditions that could cause a minor degree of entrainment. Both scenarios provide examples of potential behaviour during periods of a spill event, once the oil reaches the surface.

2.3.8.2 Unstabilised Torosa Condensate (Surface/Subsea)

Weathering results are presented for the unstabilised Torosa Condensate mixture that was used in the modelling of the sea-surface release phase, referred to as unstabilised Torosa Condensate (surface), and for the unstabilised Torosa Condensate mixture that was used in the modelling of the subsea release phase, referred to as unstabilised Torosa Condensate (subsea).

The results for the constant-wind case indicate that a significant proportion of unstabilised Torosa Condensate (surface, Figure 2.21; subsea, Figure 2.23) will tend to persist on the sea surface (46% and 15%, respectively, after 7 days) during calm wind conditions, with low levels of entrainment and around 40% (surface) and 70% (subsea) of the spilled volume expected to evaporate within the first 24 hours under light winds. The results for the variable-wind case (surface, Figure 2.22; subsea, Figure 2.24) indicate that the wind conditions will have a large impact on the proportion of unstabilised Torosa Condensate that remains afloat, with very little oil mass predicted to persist on the sea surface (<2% after 24 hours). This is largely due to the higher wind speeds within this test case (>5 knots) generating significant entrainment events, with almost all of the oil mass becoming entrained shortly after release. The higher proportion of entrained oil predicted in the variable-wind case also results in a larger proportion of the oil dissolving: 30% (surface) and 16% (subsea) after 7 days compared with <6% under calm conditions.

The evaporation rate observed in the first 24 hours is similar in both weathering tests; however, as the wind speed increases in the variable-wind case, increased entrainment reduces the proportion of oil available for evaporation, resulting in around 17% (surface) and 50% (subsea) of the spill volume expected to evaporate after 7 days as compared to 39% (surface) and 69% (subsea) in the lower-wind case.

Biological and photochemical degradation is predicted to contribute to the decay of the floating slicks in both weathering cases, with increased levels of entrainment and dissolution in the variable-wind case resulting in a higher proportion of oil decaying: 25% (surface) and 16% (subsea) after 7 days compared with 12% (surface) and 6% (subsea) under calm conditions.

Under calm conditions where entrainment is restricted, a proportion of the spilled mass of unstabilised Torosa Condensate will be expected to remain floating on the water surface. In these circumstances, some components of the remaining floating oil will evaporate and/or degrade over time scales of several weeks to a few months, with the entrained oil reducing concentration through degradation over similar time scales. This long weathering duration will extend the area of potential effect, requiring the break-up and dispersion of the slicks to reduce concentrations below the thresholds considered in this study.

2.3.8.3 Stabilised Torosa Condensate

The results for the constant-wind case (Figure 2.25) indicate that a small proportion of stabilised Torosa Condensate will tend to persist on the sea surface (6% after 7 days) during calm wind conditions, with negligible levels of entrainment and around 80% of the spilled volume expected to evaporate within the first 24 hours under light winds. The results for the variable-wind case (Figure 2.26) indicate that the wind conditions will have a large impact on the proportion of stabilised Torosa Condensate that remains afloat, with very little oil mass predicted to persist on the sea surface (<1% after 24 hours). This is largely due to the higher wind speeds within this test case (>5 knots) generating significant entrainment events, with almost all of the oil mass becoming entrained shortly after release. The higher proportion of entrained oil predicted in the variable-wind case also results in a larger proportion of the oil dissolving: 11% after 7 days compared with <2% under calm conditions.

The evaporation rate observed in the first 24 hours is similar in both weathering tests; however, as the wind speed increases in the variable-wind case, increased entrainment reduces the proportion of oil available for evaporation, resulting in around 73% of the spill volume expected to evaporate after 7 days as compared to 84% in the lower-wind case.

Biological and photochemical degradation is predicted to contribute to the decay of the floating slicks in both weathering cases, with increased levels of entrainment and dissolution in the variable-wind case resulting in a higher proportion of oil decaying: 8% after 7 days compared with 3% under calm conditions.

Under calm conditions where entrainment is restricted, a proportion of the spilled mass of stabilised Torosa Condensate will be expected to remain floating on the water surface. In these circumstances, some components of the remaining floating oil will evaporate and/or degrade over time scales of several weeks to a few months, with the entrained oil reducing concentration through degradation over similar time scales. This long weathering duration will extend the area of potential effect, requiring the break-up and dispersion of the slicks to reduce concentrations below the thresholds considered in this study.

2.3.8.4 Marine Diesel

The mass balance forecast for the constant-wind case (Figure 2.27) for marine diesel shows that approximately 45% of the oil is predicted to evaporate within 24 hours. Under these calm conditions the majority of the remaining oil on the water surface will weather at a slower rate due to being comprised of the longer-chain compounds with higher boiling points. Evaporation of the residual compounds will slow significantly, and they will then be subject to more gradual decay through biological and photochemical processes.

Under the variable-wind case (Figure 2.28), where the winds are of greater strength, entrainment of marine diesel into the water column is indicated to be significant. Approximately 24 hours after the spill, around 45% of the oil mass is forecast to have entrained and a further 35% is forecast to have evaporated, leaving only a small proportion of the oil floating on the water surface (<1%). The residual compounds will tend to remain entrained beneath the surface under conditions that generate wind waves (approximately >6 m/s).

The increased level of entrainment in the variable-wind case will result in a higher percentage of biological and photochemical degradation, where the decay of the floating slicks and oil droplets in the water column occurs at an approximate rate of 1.8% per day with an accumulated total of ~13% after 7 days, in comparison to a rate of ~0.2% per day and an accumulated total of 1.5% after 7 days in the constant-wind case. Given the large proportion of entrained oil and the tendency for it to remain mixed in the water column, the remaining hydrocarbons will decay and/or evaporate over time scales of several weeks to a few months. This long weathering duration will extend the area of potential effect, requiring the break-up and dispersion of the slicks and droplets to reduce concentrations below the thresholds considered in this study.

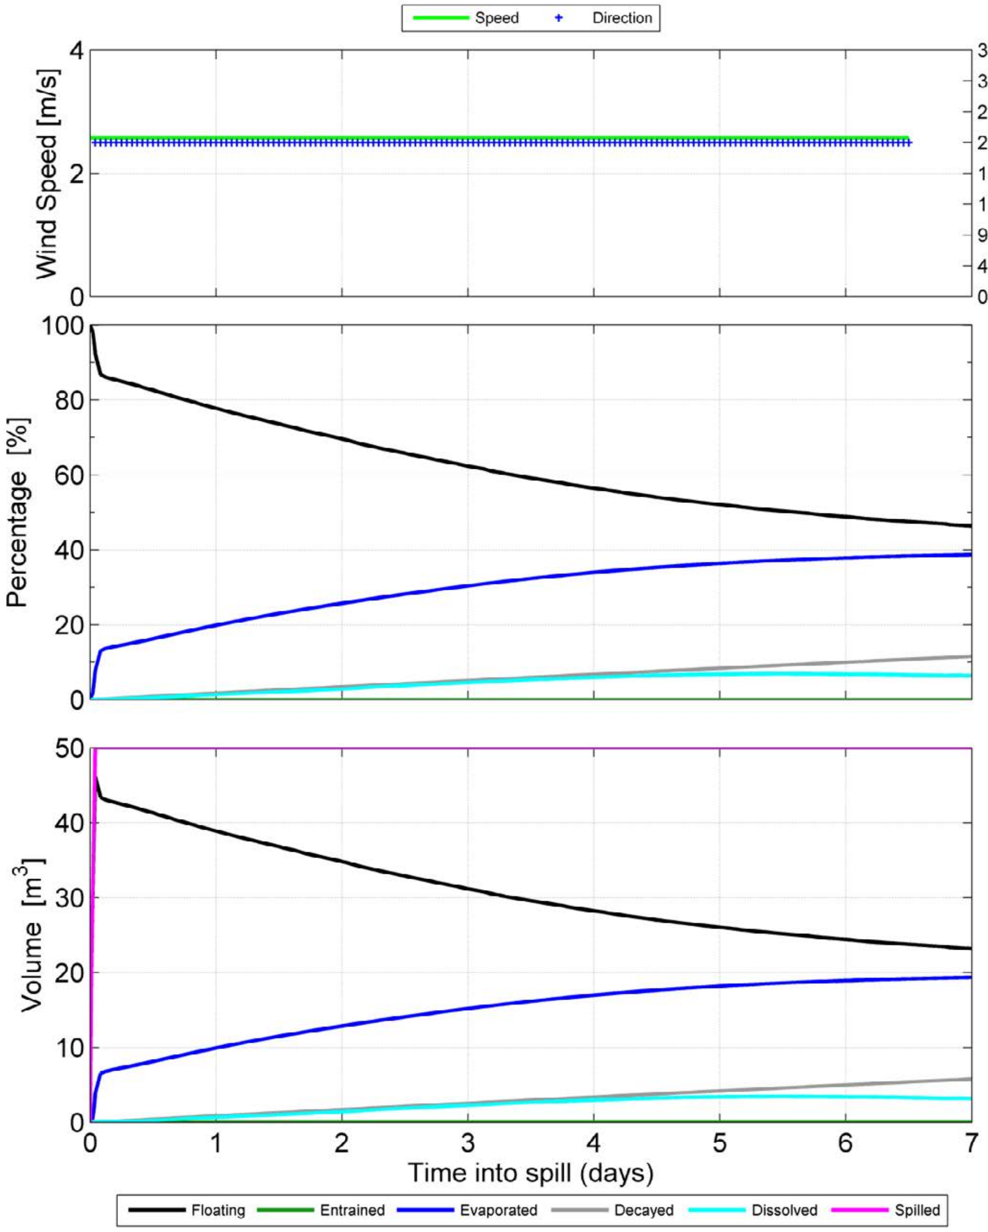

Figure 2.21 Mass balance plot representing, as proportion (middle panel) and volume (bottom panel), the weathering of unstabilised Torosa Condensate (surface) spilled onto the water surface as a one-off release (50 m^3 over 1 hour) and subject to a constant 5 kn (2.6 m/s) wind at 27 °C water temperature and 25 °C air temperature.

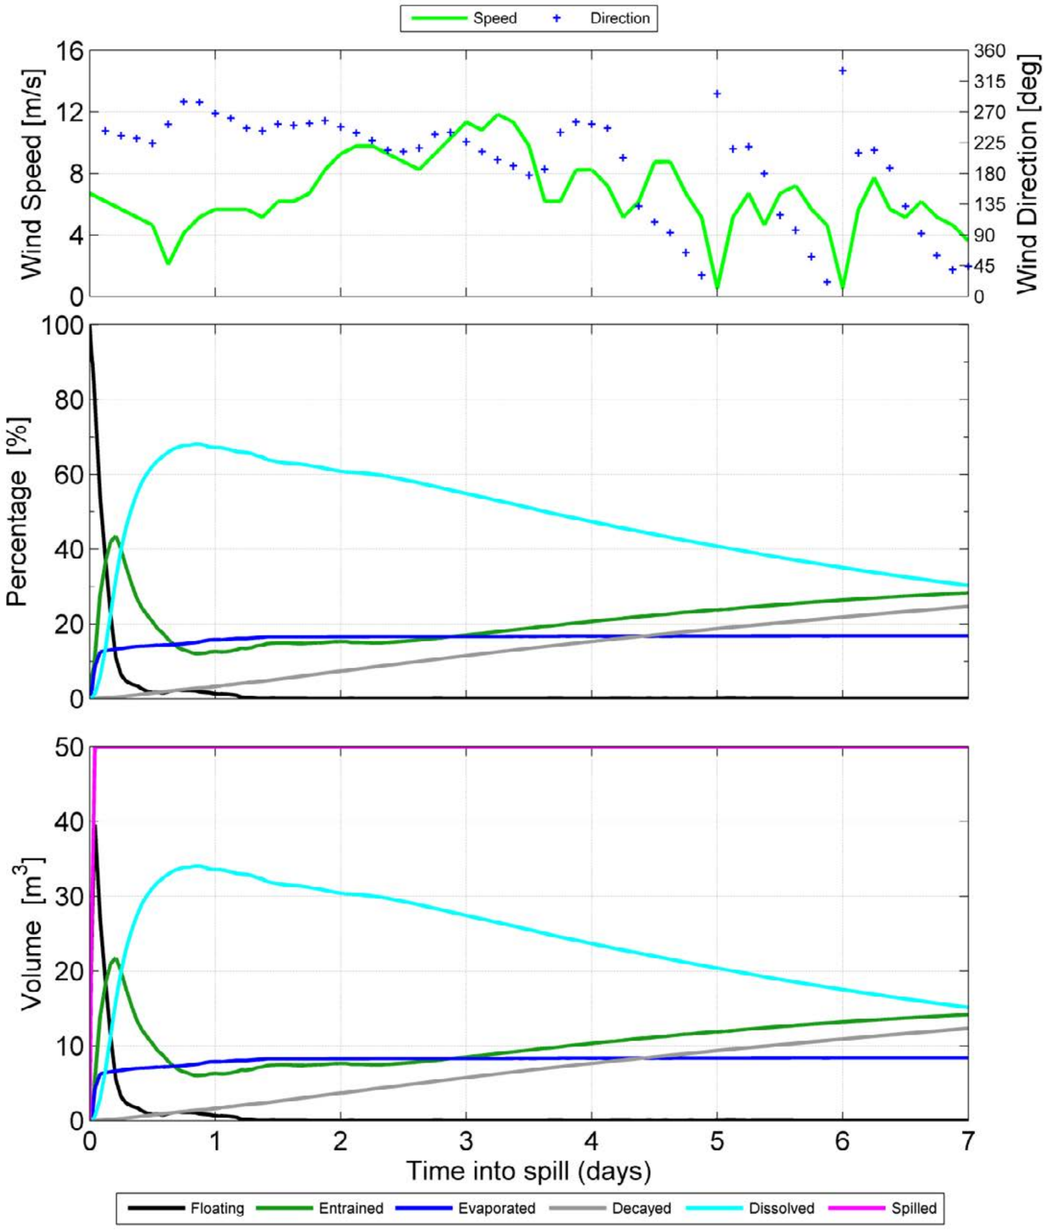

Figure 2.22 Mass balance plot representing, as proportion (middle panel) and volume (bottom panel), the weathering of unstabilised Torosa Condensate (surface) spilled onto the water surface as a one-off release (50 m^3 over 1 hour) and subject to variable wind at 27 °C water temperature and 25 °C air temperature.

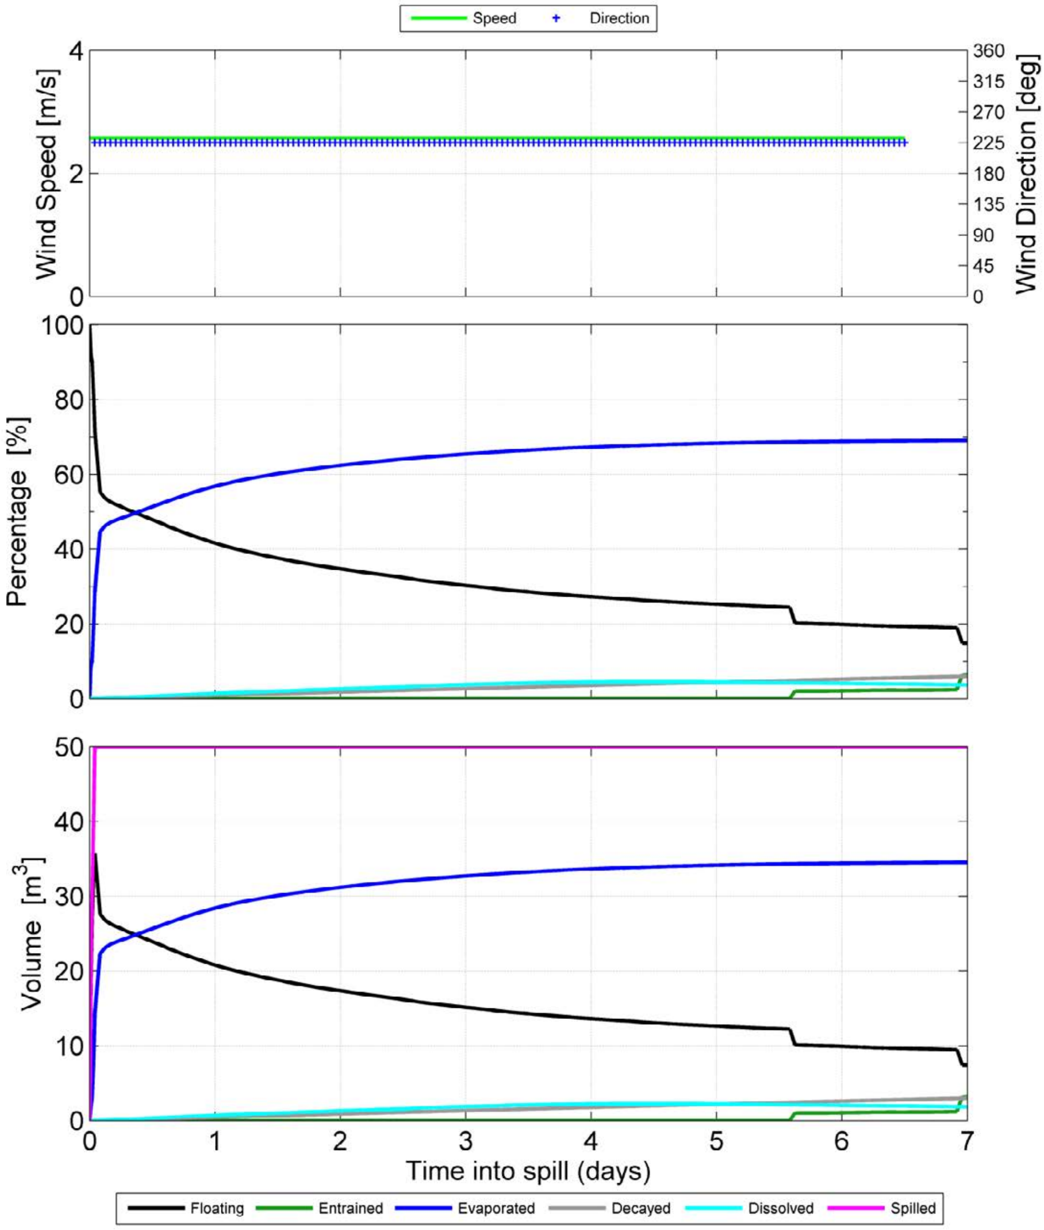

Figure 2.23 Mass balance plot representing, as proportion (middle panel) and volume (bottom panel), the weathering of unstabilised Torosa Condensate (subsea) spilled onto the water surface as a one-off release (50 m^3 over 1 hour) and subject to a constant 5 kn (2.6 m/s) wind at 27 °C water temperature and 25 °C air temperature.

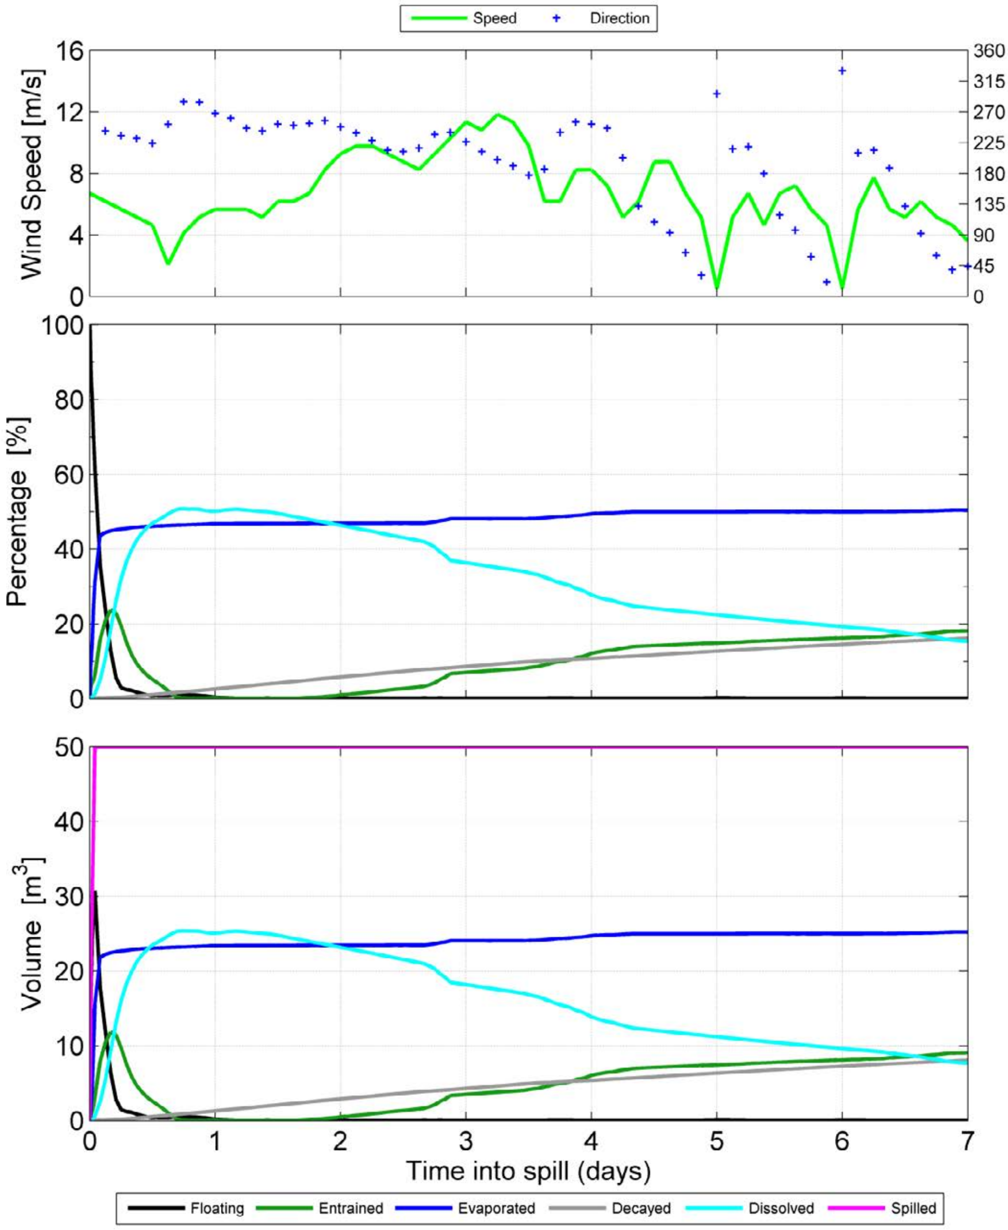

Figure 2.24 Mass balance plot representing, as proportion (middle panel) and volume (bottom panel), the weathering of unstabilised Torosa Condensate (subsea) spilled onto the water surface as a one-off release (50 m^3 over 1 hour) and subject to variable wind at 27 °C water temperature and 25 °C air temperature.

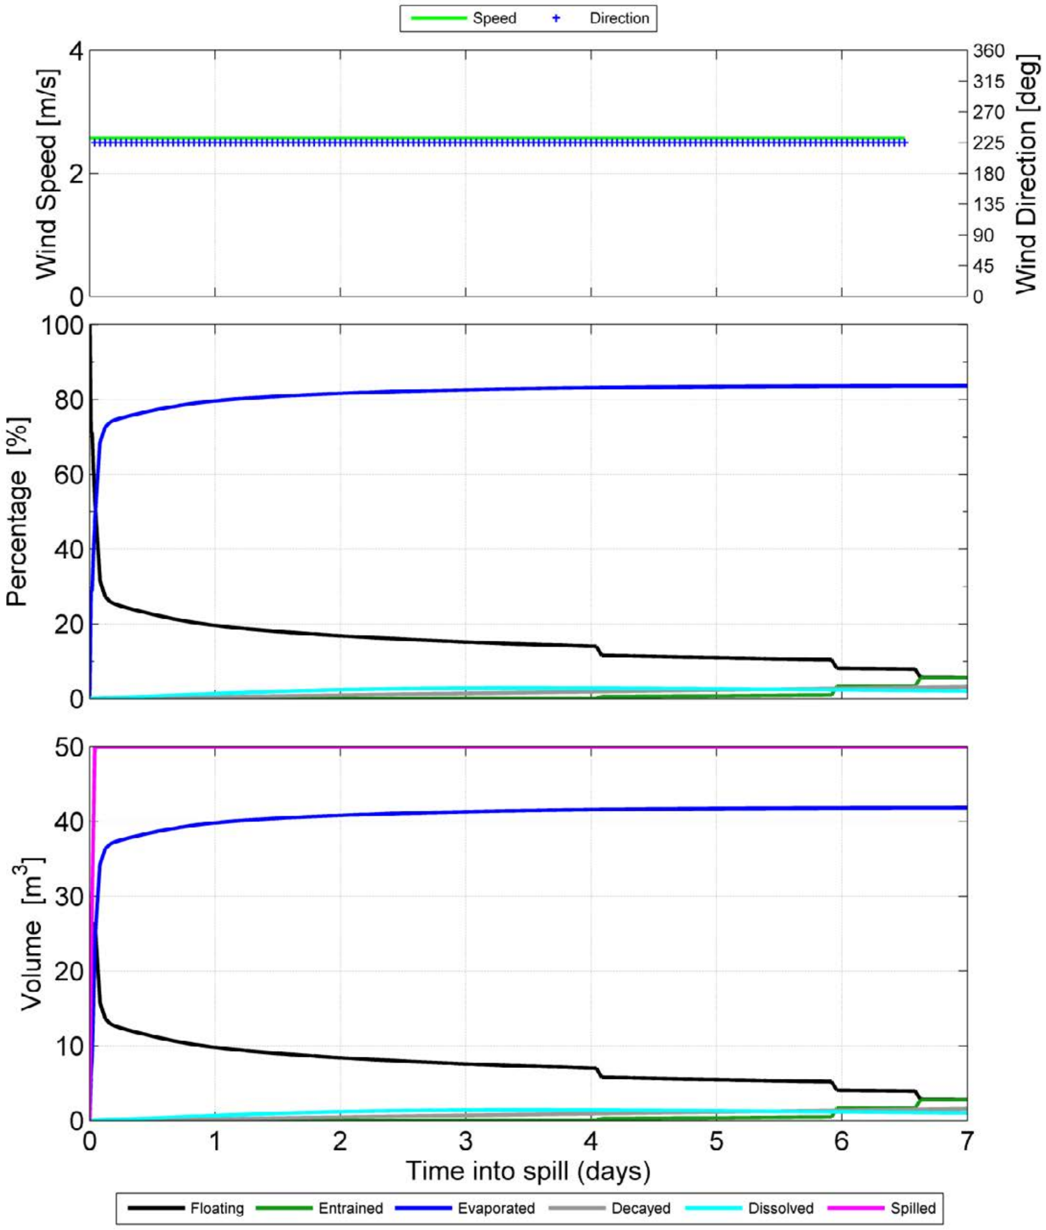

Figure 2.25 Mass balance plot representing, as proportion (middle panel) and volume (bottom panel), the weathering of stabilised Torosa Condensate spilled onto the water surface as a one-off release (50 m^3 over 1 hour) and subject to a constant 5 kn (2.6 m/s) wind at 27 °C water temperature and 25 °C air temperature.

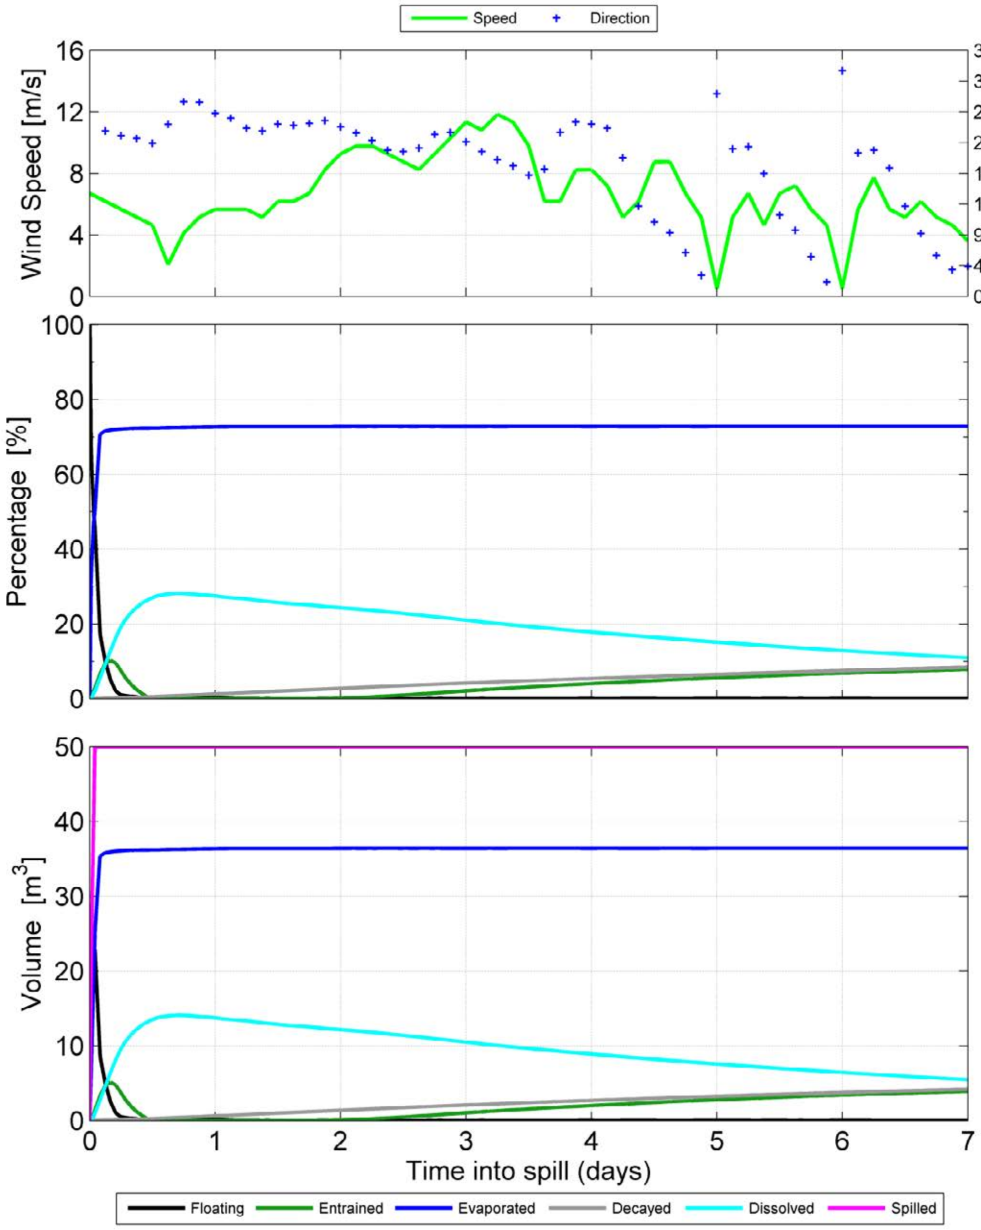

Figure 2.26 Mass balance plot representing, as proportion (middle panel) and volume (bottom panel), the weathering of stabilised Torosa Condensate spilled onto the water surface as a one-off release (50 m^3 over 1 hour) and subject to variable wind at 27 °C water temperature and 25 °C air temperature.

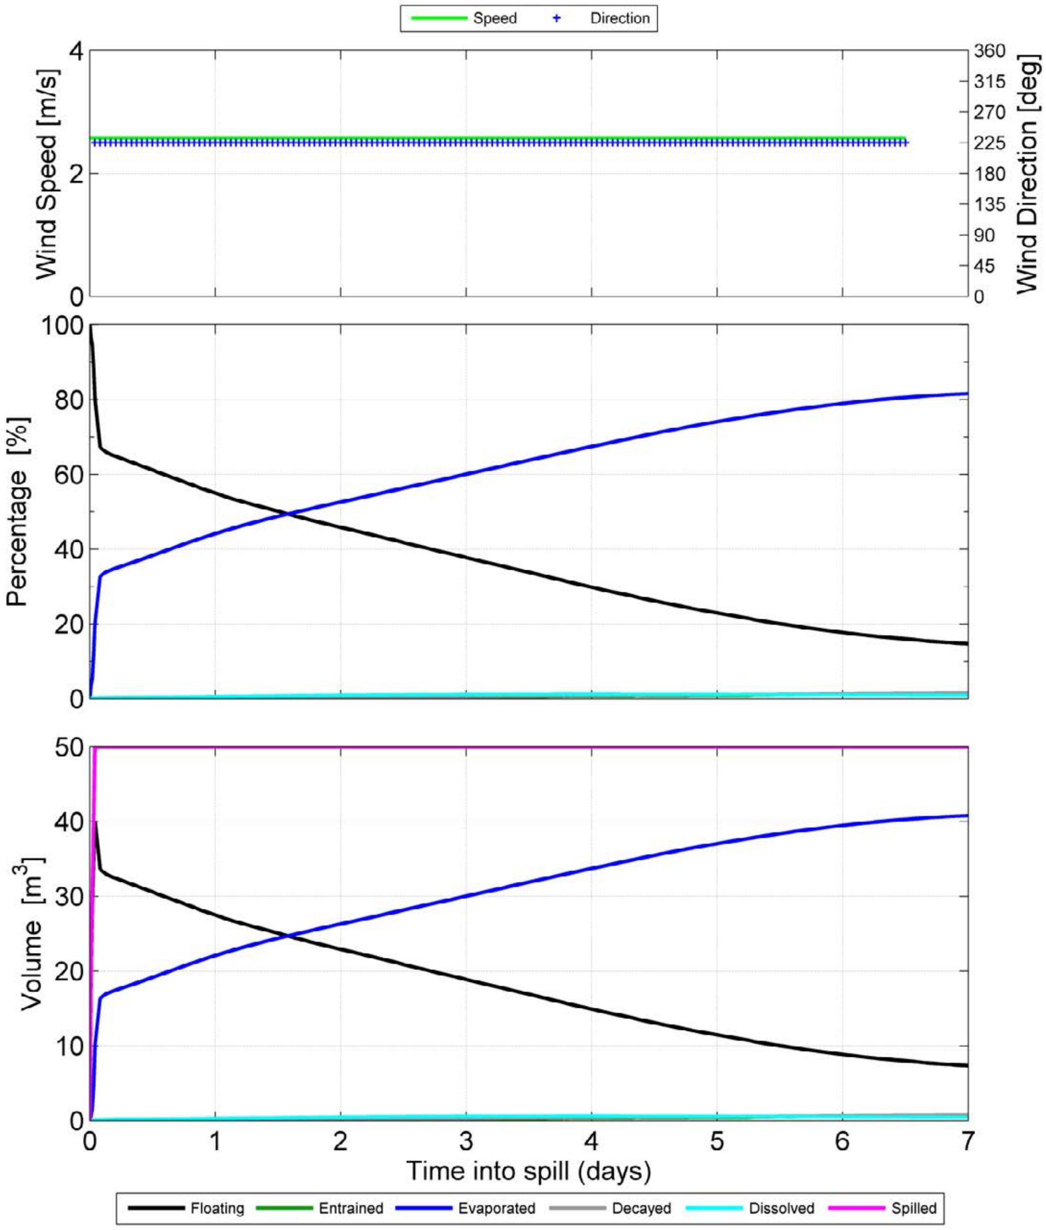

Figure 2.27 Mass balance plot representing, as proportion (middle panel) and volume (bottom panel), the weathering of marine diesel spilled onto the water surface as a one-off release (50 m^3 over 1 hour) and subject to a constant 5 kn (2.6 m/s) wind at 27 °C water temperature and 25 °C air temperature.

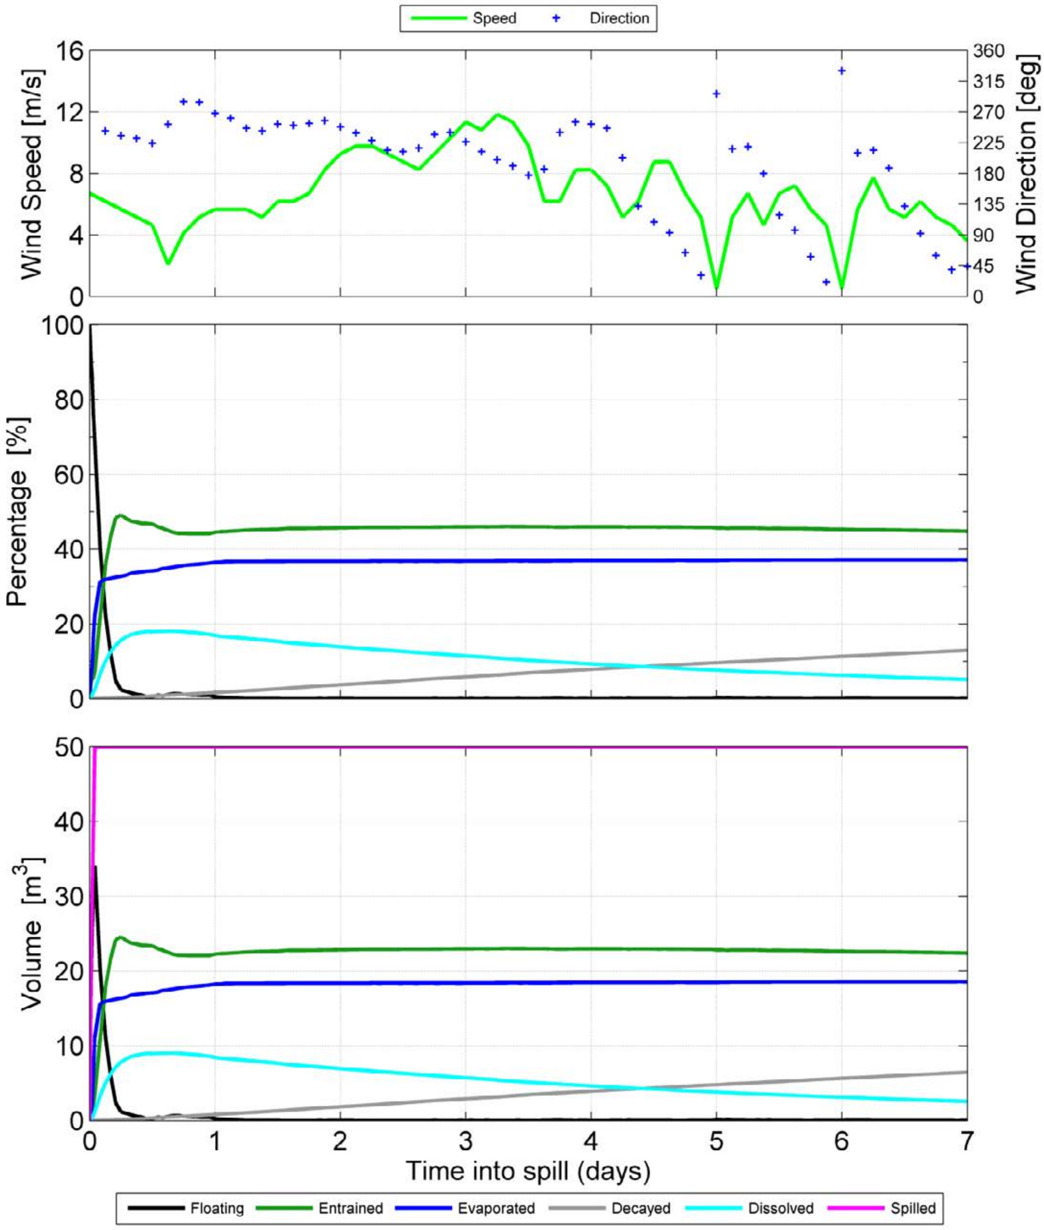

Figure 2.28 Mass balance plot representing, as proportion (middle panel) and volume (bottom panel), the weathering of marine diesel spilled onto the water surface as a one-off release (50 m^3 over 1 hour) and subject to variable wind at 27 °C water temperature and 25 °C air temperature.

2.3.9 Emulsification Characteristics

Studies have shown strong evidence that the asphaltene content of oil mixtures is the most important contributing factor for stabilising emulsions, alongside other contributing properties such as density, viscosity and resin content (Fingas, 2010; Fingas & Fieldhouse, 2004, 2015). Fingas & Fieldhouse (2005) analysed a large body of oil types for emulsion stability and defined four water-in-oil types: stable, mesostable, entrained and unstable. Only stable, mesostable and entrained water-in-oil emulsions hold a relatively high proportion of water (> ~20% and up to 80%) and will persist for long periods (several weeks to more than a year) once formed, despite a reduction in mixing energy (Figure 2.29). Oil mixtures that do not hold significant amounts of water (<6%) when mixed are characterised as unstable.

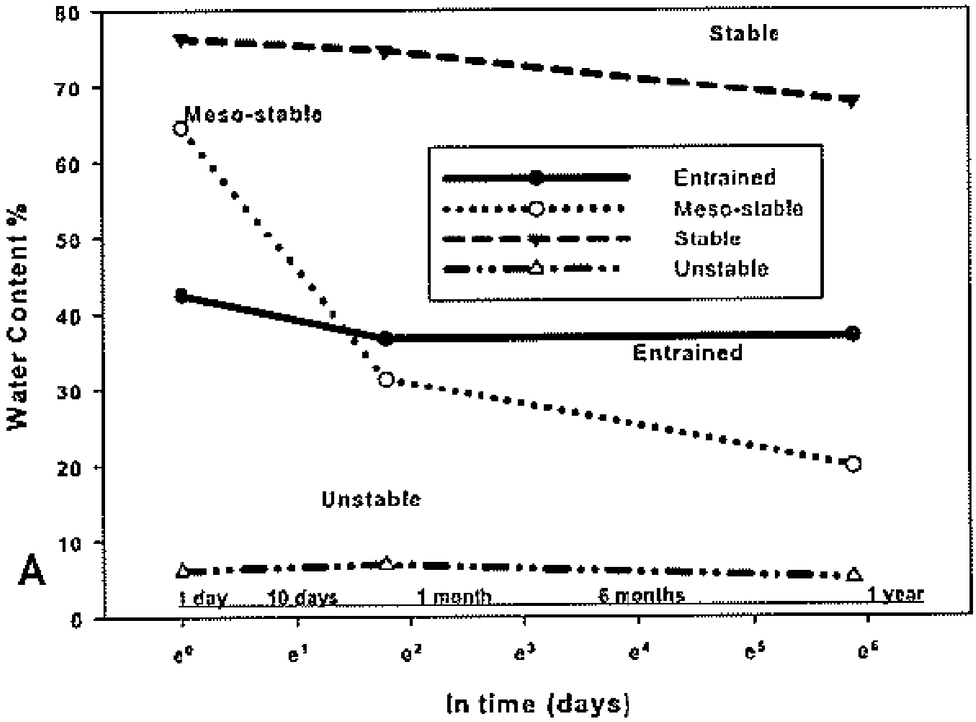

Figure 2.29 Average properties of emulsion stability groups (Fingas & Fieldhouse, 2004).

Fingas & Fieldhouse (2015) lists oil types that form stable or mesostable emulsions. Universally, these have densities ranging from 0.89 g/cm^3 to >1.0 g/cm^3, high or very high viscosities (14-20,000 cP) and high asphaltene content (1-17%). Oil types that form entrained emulsions have densities >0.96 g/cm^3 and very high viscosities (>6,000 cP). Oil types that form unstable emulsions have low asphaltene or resin content (<1%) and either low or high densities (<0.85 g/cm^3 or >1.0 g/cm^3) with either low or high viscosities (<100 cP or >800,000 cP).

The densities, viscosities and asphaltene content of the unstabilised and stabilised Torosa Condensates are indicative of unstable water-in-oil emulsion with <6% water content.

2.3.10 Subsea Discharge Characteristics

2.3.10.1 Overview

High-pressure releases that involve mixed gas and oil will tend to generate relatively small droplet sizes that have slow rise rates, due to viscous resistance imparted by the surrounding seawater, and may become trapped by density layers in the water column (Chen & Yapa, 2002). The buoyancy of the gas cloud may lift entrained oil droplets towards the surface and, in the case of blowouts in relatively shallow water (<100-200 m), the rising column of gas and entrained water can lift the oil to the surface at a substantially faster rate than would occur from the relative buoyancy of the oil alone, opposed by the viscosity of the water column.

For deeper releases (200-500 m), the gas will expand to entrain oil droplets towards the surface, but the gas and oil will then tend to separate before the oil surfaces because the gas either goes into solution or accelerates away from the oil droplets. The height at which the gas lift ceases is referred to as the trapping height. The rate at which oil rises from the trapping height will be determined by a number of factors, including the relative buoyancy of the oil versus local water density, the size of the droplets (increased viscous resistance for smaller sizes), the presence of density barriers in the water column and the action of shear currents that might be present in the water column.

Given the water temperature and pressure that would be expected at the specified discharge depth, the potential for methane and other gases to convert to gas hydrates (semi-solid crystalline structures that would affect the buoyancy of the plume; Figure 2.30) was considered in this study.

The OILMAP model, described in Section 2.1.2, was used in this study to predict the behaviour of the rising plume of gas-oil-water and the oil droplet distribution resulting from the subsea discharge in Scenario 1.

Inputs to the OILMAP model included specification of the discharge rate, hole size, gas-to-oil ratio, and the temperature of the oil on exiting and before subsequent cooling by the ambient water. The model input also included temperature and salinity profiles representative of the location. Summaries of the inputs to and outputs of the OILMAP simulations for Scenario 1 are presented in the following section.

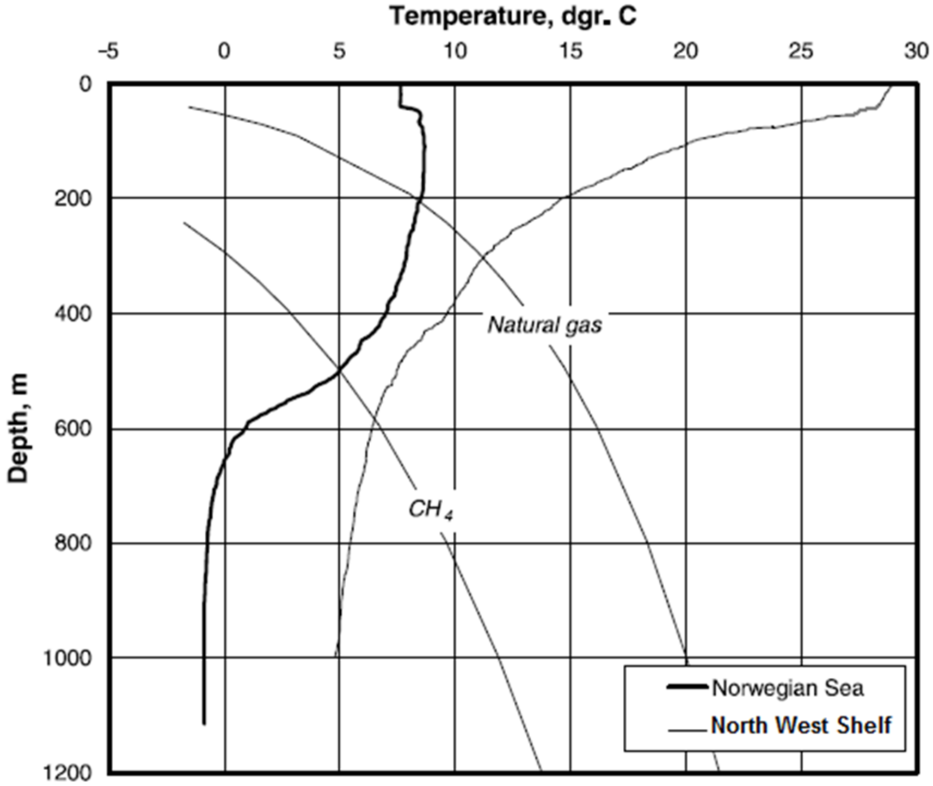

Figure 2.30 Theoretical equilibrium lines for hydrate formation based on the temperature and pressure at the release point. The line for "natural gas" assumes 80% methane, 10% ethane and 10% propane. Typical indicative sea temperature profiles with depth are indicated (Johansen, 2003).

2.3.10.2 Scenario 1: Long-Term (77-Day) Surface/Subsea Blowout of Unstabilised Torosa Condensate at the TRA-C Well

The OILMAP input parameters and the resulting output parameters that were used as input into SIMAP are presented in Table 2.4 for Scenario 1. The model input also included temperature and salinity profiles representative of the location.

The results of the OILMAP simulation for Scenario 1 predict that the discharge will generate a cone of rising gas that will entrain the oil droplets and ambient sea water up to the water surface. The mixed plume is initially forecast to jet towards the water surface with a vertical velocity of around 7.6 m/s, gradually slowing and increasing in plume diameter as more ambient water is entrained. The diameter of the central cone of rising water and oil at the point of surfacing is predicted to be approximately 27 m.

The high discharge velocity and turbulence generated by the expanding gas plume is predicted to generate relatively small oil droplets (<150 µm) that will have very low rise velocities (<0.25 cm/s). These droplets will be subject to mixing due to turbulence generated by the lateral displacement of the rising plume, as well as vertical mixing induced by wind and breaking waves. Therefore, despite reaching the surface due to the lift produced by the rising plume, the droplets will then tend to remain within the wave-mixed layer of the water column (3-10 m deep, depending on the conditions), where they can resist surfacing due to their weak buoyancy relative to other mixing processes.

The ongoing nature of the release combined with the potential for the plume to breach the water surface may present other hazards, including conditions that may lead to high local concentrations of atmospheric volatiles. These issues should be considered when evaluating the practicality of response operations at or near the blowout site. The results suggest that beyond the immediate vicinity of the blowout the majority of the released hydrocarbons will be present in the upper layers of the ocean, with the potential for oil to form floating slicks under sufficiently calm local wind conditions.

Table 2.4 Near-field subsea discharge model parameters for Scenario 1.

OILMAP	Parameter	Value
Inputs	Release depth (m BMSL)	425
	Oil density (g/cm^3) (at 20 °C)	0.78
	Oil viscosity (cP) (at 20 °C)	1.09
	Oil temperature (°C)	139
	Hole diameter (m) [in]	0.22 [8.5]
	Gas:oil ratio (m^3/m^3) [scf/bbl]	17,632 [98,992]
	Oil flow rate (m^3/d) [bbl/d]	1,845 [11,607]
Outputs	Plume diameter (m)	27.2
	Plume height (m ASB)	425 (surface)
	Plume initial rise velocity (m/s)	7.6
	Plume terminal rise velocity (m/s)	5.1
Predicted Oil Droplet Size Distribution	20% droplets of size (μm)	37.4
	20% droplets of size (μm)	54.6
	20% droplets of size (μm)	70.9
	20% droplets of size (μm)	92.2
	20% droplets of size (μm)	134.6

3 STOCHASTIC ASSESSMENT RESULTS

3.1 Overview

Predictions for the probability of contact and time to contact by oil concentrations equalling or exceeding defined thresholds for floating oil, entrained oil and dissolved aromatic hydrocarbons are provided in the following sections to summarise the results of the annualised stochastic modelling.

Contour maps present estimates for the annualised probability of contact by instantaneous concentrations of at least the defined minimum threshold concentrations (1 g/m^2, 10 g/m^2, 50 g/m^2 and 100 g/m^2 for floating oil; 100 g/m^2 and 250 g/m^2 for shoreline oil; 500 ppb for entrained oil and dissolved aromatic hydrocarbons) for at least one time step. These contours summarise the outcomes for all replicate simulations commencing across the annual period – a total of 100 replicate simulations for Scenario 1 and 200 replicate simulations for Scenarios 2 to 4.

Readers should note that the contour maps presented in this report do not represent the predicted coverage of any one hydrocarbon spill or a depiction of a slick or plume at any particular instant in time. Rather, the contours are a composite of a large number of theoretical slick paths, integrated over the full duration of the simulations relevant to the assessed scenario. The contour maps should be treated as indications of the probability of exposure at defined concentrations, for individual locations, at some point in time after the defined spill commences, given the trends and variations in metocean conditions that occur around the study area.

Locations with higher probability ratings were exposed during a greater number of spill simulations, indicating that the combination of the prevailing wind and current conditions are more likely to result in contact to these locations if the spill scenario were to occur in the future. The areas outside of the lowest-percentage contour indicate that contact will be less likely under the range of prevailing conditions for this region than areas falling within higher probability contours. It is important to note that the probabilities are derived from the samples of data used in the modelling. Therefore, locations that are not calculated to receive exposure at threshold concentrations or greater in any of the replicate simulations might possibly be contacted if very unusual conditions were to occur. Hence, we do not attribute a probability of nil to areas beyond the lowest probability contour.

Tables are presented to summarise estimates of contact risk for locations within potentially sensitive receptors that were defined by Woodside. All sensitive receptors historically considered for Woodside spill risk assessments were included in the analysis, with those outlined here being the receptors shown to be at risk of contact for each assessed scenario.

The probability estimates for contact by floating oil that are presented in the tables summarise the probability that oil will arrive at shorelines as floating films at the specified threshold concentration or greater for at least one time step (1 hour).

The minimum time estimates shown in the tables present the shortest time for any oil to drift from the source to any part of the sensitive receptor, relative to the commencement of the spill. These times then indicate the minimum weathering time for oil that might make contact with the resource.

The mean and maximum shoreline concentrations indicate the concentrations forecast to potentially accumulate over time on any discrete part of a shoreline (calculated for individual portions of 0.8 km length). Accumulated concentrations are calculated by summing the mass of oil that arrives at any concentration (including < threshold) over time at a model cell and subtracting any mass lost through evaporation and washing off, where relevant.

The maximum local accumulated concentration in the worst replicate spill is the greatest accumulation predicted for any point on the shoreline during any replicate simulation, and thus represents an extreme estimate. The maximum local accumulated concentration averaged over all replicate spills is the greatest concentration calculated for any point on the shoreline after averaging over all replicate simulations.

Note that it is possible that oil films arriving at concentrations that are less than the threshold may accumulate over the course of a spill event to result in concentrations that apparently exceed the threshold. Hence, the mean expected and maximum concentrations of accumulated oil can exceed the threshold applied to the probability calculations for the arrival of floating oil even where no instantaneous exceedances above threshold are predicted. It is important to understand that the two parameters (floating concentration and shoreline concentration) are quite distinct, calculated in different ways and representative of alternative outcomes. The floating probability estimates and the shoreline accumulative estimates should therefore be treated as independent estimators of different exposure outcomes, and not directly compared.

For the entrained and dissolved components, the tabulated results summarise interrogations of cells representing the water surrounding the sensitive receptor shorelines (or submerged features), with individual buffer zones. Buffer zones were defined with consideration of the bathymetry bordering each receptor, natural boundaries, or sensible legislative boundaries.

The modelling for each assessed scenario assumed no mitigation efforts are undertaken to collect or otherwise affect the natural transport and weathering of the oil.

The predicted outcomes based on the modelling results are discussed in the following sections in terms of floating, entrained and dissolved aromatic hydrocarbons. Discussion is based around the outcomes of stochastic risk contours. Plots of the Environment that May Be Affected (EMBA) and minimum time to exceedance of concentration thresholds are presented for the assessed thresholds.

Figure 3.1 shows transect lines intersecting at the release locations along which maximum entrained oil and dissolved aromatic hydrocarbon concentrations in the water column were extracted for each assessed scenario.

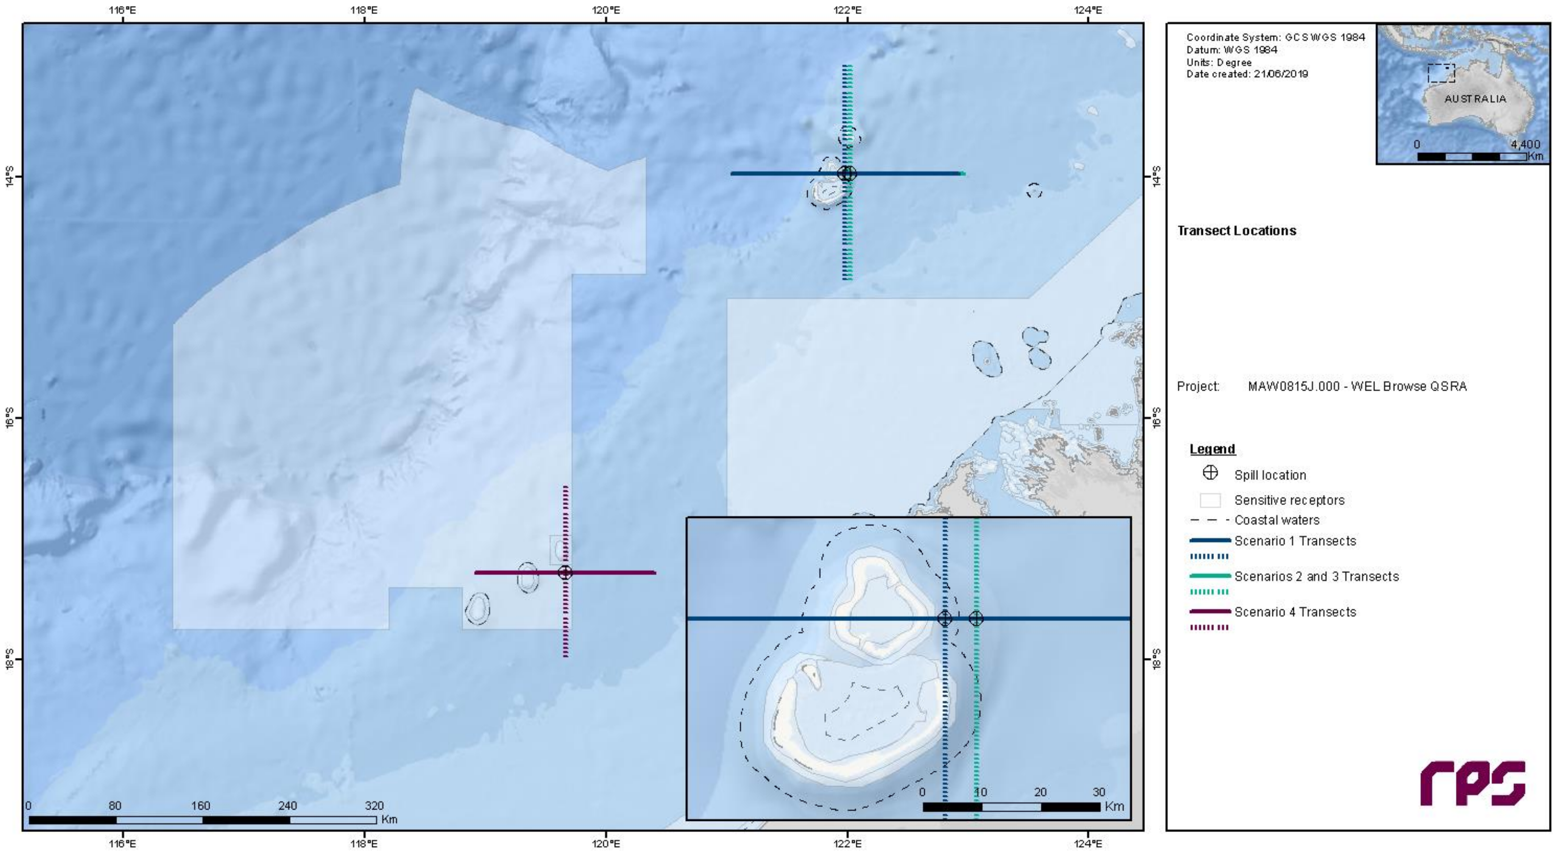

Figure 3.1 Locations of cross-sections, over a varying latitude (dashed line) and longitude (solid line), along which the distributions of maximum entrained oil and dissolved aromatic hydrocarbon concentrations were extracted for each spill scenario in this study.

3.2 Scenario 1: Long-Term (77-Day) Surface/Subsea Blowout of Unstabilised Torosa Condensate at the TRA-C Well

3.2.1 Discussion of Results

3.2.1.1 Overview

This scenario investigated the probability of exposure to surrounding regions by oil resulting from a long-term (77-day) surface/subsea release of 142,154 m^3 of unstabilised Torosa Condensate at the TRA-C well during operations at any time of year, with no mitigation measures applied.

During the initial surface release phase, the volatile fractions of the oil (16.5%) are likely to evaporate within 24 hours of exposure to the atmosphere. The low-volatility fraction of the condensate (32.8%) will take longer times of the order of days to weeks to evaporate, and the remaining fraction (50.7%) is expected to persist for an extended period of time as residual oil.

During the subsea release phase, the small oil droplets rapidly transported to the sea surface by the rising gas plume will be susceptible to re-entrainment into the wave mixed layer under typical wind conditions. It is likely that the bulk of the oil mass will remain entrained in the water column until degradation processes occur. Due to the weak buoyancy of the oil droplets, the formation of floating slicks is unlikely, and therefore only a small fraction of the volatile compounds is likely to be exposed to the atmosphere. Considering the spill volume and low levels of evaporation expected, there is a high potential for dissolution of soluble aromatic compounds.

3.2.1.2 Floating and Shoreline Oil

The probability contour figures for floating oil indicate that concentrations equal to or greater than the 10 g/m^2 threshold could potentially be found, in the form of slicks, up to 143 km from the spill site (Figure 3.3).

The Scott Reef South, Scott Reef Central and Scott Reef Central – Sandy Islet shoreline receptors are predicted to be contacted by floating oil concentrations at the 10 g/m^2 threshold with probabilities of 45%, 9% and 8%, respectively (Table 3.1). At these receptors, the corresponding minimum times to contact at this threshold are 18 hours, 42 hours and 46 hours.

The Scott Reef South, Scott Reef Central and Scott Reef Central – Sandy Islet receptors are predicted to experience shoreline oil accumulation in excess of the 100 g/m^2 threshold with a probability of 92% (Table 3.1). Potential for accumulation of oil on shorelines is predicted to be significant, with a maximum accumulated volume of 827 m^3 and a maximum local accumulated concentration of 34.3 kg/m^2 forecast at these receptors (Table 3.1). The predicted zone of shoreline impact is restricted to Sandy Islet, at which these three receptors overlap. Sandy Islet is treated as an emergent feature, while the intertidal reefs to the north and south are treated as submerged features for the purposes of this study.

The forecast annualised minimum times to contact and EMBA for floating oil at or above the 1 g/m^2 and 10 g/m^2 threshold concentrations are depicted in Figure 3.4 to Figure 3.7.

3.2.1.3 Entrained Oil

Entrained oil at concentrations equal to or greater than the 100 ppb threshold is predicted to be found up to around 863 km from the spill site (Figure 3.9).

Contact by entrained oil at concentrations equal to or greater than 100 ppb is predicted at Scott Reef North, Scott Reef North – Flats and Scott Reef North – Lagoon with probabilities of 100% (Table 3.2). The maximum entrained oil concentration forecast for any receptor is predicted as 23.6 ppm at Scott Reef North.

The forecast annualised minimum times to contact and EMBA for entrained oil at or above the 100 ppb threshold concentration are depicted in Figure 3.10 and Figure 3.11, respectively.

The cross-sectional transects of maximum entrained oil concentrations in the vicinity of the release site show that concentrations above 25,000 ppb are expected to extend from the sea surface to depths of around 20 m (Figure 3.12).

3.2.1.4 Dissolved Aromatic Hydrocarbons

Dissolved aromatic hydrocarbons at concentrations equal to or greater than the 50 ppb threshold are predicted to be found up to around 673 km from the spill site (Figure 3.13).

Contact by dissolved aromatic hydrocarbons at concentrations equal to or greater than 50 ppb is predicted at Scott Reef North, Scott Reef North – Flats and Scott Reef North – Lagoon with probabilities of 100% (Table 3.3). The maximum dissolved aromatic hydrocarbon concentration forecast for any receptor is predicted as 13.9 ppm at Scott Reef North.

The forecast annualised minimum times to contact and EMBA for dissolved aromatic hydrocarbons at or above the 500 ppb threshold concentration are depicted in Figure 3.14 and Figure 3.15, respectively.

The cross-sectional transects of maximum dissolved aromatic hydrocarbon concentrations in the vicinity of the release site show that concentrations above 10,000 ppb are expected to extend from the sea surface to depths of around 20 m (Figure 3.16).

3.3 Scenario 2: Short-Term (24-Hour) Surface Release of Stabilised Torosa Condensate after a Vessel Cargo Tank Rupture at the Torosa FPSO Location

3.3.1 Discussion of Results

3.3.1.1 Overview

This scenario investigated the probability of exposure to surrounding regions by oil resulting from a short-term (24-hour) surface release of 18,000 m^3 of stabilised Torosa Condensate after a vessel cargo tank rupture from a vessel collision at the Torosa FPSO location during operations at any time of year, with no mitigation measures applied.

During the surface release, the volatile fractions of the oil (78.0%) are likely to evaporate within 24 hours of exposure to the atmosphere. The low-volatility fraction of the condensate (8.0%) will take longer times of the order of days to weeks to evaporate, and the remaining fraction (14.0%) is expected to persist for an extended period of time as residual oil.

3.3.1.2 Floating and Shoreline Oil

The probability contour figures for floating oil indicate that concentrations equal to or greater than the 10 g/m^2 threshold could potentially be found, in the form of slicks, up to 126 km from the spill site (Figure 3.18).

The Scott Reef South and Scott Reef Central shoreline receptors are predicted to be contacted by floating oil concentrations at the 10 g/m^2 threshold with probabilities of 6.5% and 2%, respectively (Table 3.4). At these receptors, the corresponding minimum times to contact at this threshold are 21 hours and 57 hours.

The Scott Reef South, Scott Reef Central and Scott Reef Central – Sandy Islet receptors are predicted to experience shoreline oil accumulation in excess of the 100 g/m^2 threshold with a probability of 20.5% (Table 3.4). Potential for accumulation of oil on shorelines is predicted to be moderate, with a maximum accumulated volume of 212 m^3 and a maximum local accumulated concentration of 9.5 kg/m^2 forecast at these receptors (Table 3.4).

The forecast annualised minimum times to contact and EMBA for floating oil at or above the 1 g/m^2 and 10 g/m^2 threshold concentrations are depicted in Figure 3.19 to Figure 3.22.

3.3.1.3 Entrained Oil

Entrained oil at concentrations equal to or greater than the 100 ppb threshold is predicted to be found up to around 890 km from the spill site (Figure 3.24).

Contact by entrained oil at concentrations equal to or greater than 100 ppb is predicted at Scott Reef North (48.5%), Scott Reef North – Flats (46%) and Scott Reef North – Lagoon (40%), as well as several other sensitive receptors with probabilities of less than 30% (Table 3.5). The maximum entrained oil concentration forecast for any receptor is predicted as 30.5 ppm at Scott Reef North. This is greater than the maximum concentration forecast in Scenario 1, and this result is attributable to the equivalent release rate in Scenario 2 being higher (1,846 m^3/day of unstabilised Torosa Condensate each day versus 18,000 m^3/day of stabilised Torosa Condensate in one day). The oil plume will initially be more concentrated in the latter case and will be likely to move as a more coherent mass for a sustained duration before diffusion processes act to reduce the peak concentrations.

The forecast annualised minimum times to contact and EMBA for entrained oil at or above the 100 ppb threshold concentration are depicted in Figure 3.25 and Figure 3.26, respectively.

The cross-sectional transects of maximum entrained oil concentrations in the vicinity of the release site show that concentrations above 25,000 ppb are expected to extend from the sea surface to depths of around 20 m (Figure 3.27).

3.3.1.4 Dissolved Aromatic Hydrocarbons

Dissolved aromatic hydrocarbons at concentrations equal to or greater than the 50 ppb threshold are predicted to be found up to around 517 km from the spill site (Figure 3.28).

Contact by dissolved aromatic hydrocarbons at concentrations equal to or greater than 50 ppb is predicted at Scott Reef North (41.5%), Scott Reef North – Flats (39.5%) and Scott Reef North – Lagoon (33.5%), as well as several other receptors with probabilities of less than 25% (Table 3.6). The maximum dissolved aromatic hydrocarbon concentration forecast for any receptor is predicted as 12.7 ppm at Scott Reef North.

The forecast annualised minimum times to contact and EMBA for dissolved aromatic hydrocarbons at or above the 50 ppb threshold concentration are depicted in Figure 3.29 and Figure 3.30, respectively.

The cross-sectional transects of maximum dissolved aromatic hydrocarbon concentrations in the vicinity of the release site show that concentrations above 10,000 ppb are expected to extend from the sea surface to depths of around 15 m (Figure 3.31).

3.4 Scenario 3: Short-Term (Instantaneous) Surface Release of Stabilised Torosa Condensate after an FPSO Offtake System Failure at the Torosa FPSO Location

3.4.1 Discussion of Results

3.4.1.1 Overview

This scenario investigated the probability of exposure to surrounding regions by oil resulting from a short-term (instantaneous) surface release of 768 m^3 of stabilised Torosa Condensate after an FPSO offtake system failure at the Torosa FPSO location during operations at any time of year, with no mitigation measures applied.

During the surface release, the volatile fractions of the oil (78.0%) are likely to evaporate within 24 hours of exposure to the atmosphere. The low-volatility fraction of the condensate (8.0%) will take longer times of the order of days to weeks to evaporate, and the remaining fraction (14.0%) is expected to persist for an extended period of time as residual oil.

3.4.1.2 Floating and Shoreline Oil

The probability contour figures for floating oil indicate that concentrations equal to or greater than the 10 g/m^2 threshold could potentially be found, in the form of slicks, up to 67 km from the spill site (Figure 3.33).

The Scott Reef South shoreline receptor is predicted to be contacted by floating oil concentrations at the 10 g/m^2 threshold with a probability of 1.5% and a minimum contact time of 24 hours (Table 3.7).

The Scott Reef South, Scott Reef Central and Scott Reef Central – Sandy Islet receptors are predicted to experience shoreline oil accumulation in excess of the 100 g/m^2 threshold with a probability of 2.5% (Table 3.7). Potential for accumulation of oil on shorelines is predicted to be low, with a maximum accumulated volume of 8 m^3 and a maximum local accumulated concentration of 715 g/m^2 forecast at these receptors (Table 3.7).

The forecast annualised minimum times to contact and EMBA for floating oil at or above the 1 g/m^2 and 10 g/m^2 threshold concentrations are depicted in Figure 3.34 to Figure 3.37.

3.4.1.3 Entrained Oil

Entrained oil at concentrations equal to or greater than the 100 ppb threshold is predicted to be found up to around 242 km from the spill site (Figure 3.39).

Contact by entrained oil at concentrations equal to or greater than 100 ppb is predicted at Scott Reef North (28%), Scott Reef North – Flats (25%) and Scott Reef North – Lagoon (20%; Table 3.8). The maximum entrained oil concentration forecast for any receptor is predicted as 6.4 ppm at Scott Reef North and Scott Reef North – Flats.

The forecast annualised minimum times to contact and EMBA for entrained oil at or above the 100 ppb threshold concentration are depicted in Figure 3.40 and Figure 3.41, respectively.

The cross-sectional transects of maximum entrained oil concentrations in the vicinity of the release site show that concentrations above 15,000 ppb are expected to extend from the sea surface to depths of around 15 m (Figure 3.42).

3.4.1.4 Dissolved Aromatic Hydrocarbons

Dissolved aromatic hydrocarbons at concentrations equal to or greater than the 50 ppb threshold are predicted to be found up to around 271 km from the spill site (Figure 3.43).

Contact by dissolved aromatic hydrocarbons at concentrations equal to or greater than 50 ppb is predicted at Scott Reef North (23%) and Scott Reef North – Flats (22.5%; Table 3.9). The maximum dissolved aromatic hydrocarbon concentration forecast for any receptor is predicted as 1.8 ppm at Scott Reef North and Scott Reef North – Lagoon.

The forecast annualised minimum times to contact and EMBA for dissolved aromatic hydrocarbons at or above the 50 ppb threshold concentration are depicted in Figure 3.44 and Figure 3.45, respectively.

The cross-sectional transects of maximum dissolved aromatic hydrocarbon concentrations in the vicinity of the release site show that concentrations above 1,000 ppb are expected to extend from the sea surface to depths of around 10 m (Figure 3.46).

3.5 Scenario 4: Short-Term (Instantaneous) Surface Release of Marine Diesel after a Vessel Fuel Tank Rupture near the Rowley Shoals

3.5.1 Discussion of Results

3.5.1.1 Overview

This scenario investigated the probability of exposure to surrounding regions by oil resulting from a short-term (instantaneous) surface release of 2,000 m^3 of marine diesel after a vessel fuel tank rupture from a vessel collision near the Rowley Shoals during operations at any time of year, with no mitigation measures applied.

During the surface release, the volatile fractions of the oil (40.6%) are likely to evaporate within 24 hours of exposure to the atmosphere. The low-volatility fraction of the diesel (54.4%) will take longer times of the order of days to weeks to evaporate, and the remaining fraction (5.0%) is expected to persist for an extended period of time as residual oil.

3.5.1.2 Floating and Shoreline Oil

The probability contour figures for floating oil indicate that concentrations equal to or greater than the 10 g/m^2 threshold could potentially be found, in the form of slicks, up to 82 km from the spill site (Figure 3.48).

Given that the spill location lies within the Argo-Rowley Terrace Marine Park area, floating oil at concentrations equal to or greater than 100 g/m^2 is forecast at this receptor with a probability of 100% and a minimum time to contact of less than 1 hour (Table 3.10). The Rowley Shoals – Mermaid Reef Marine Park shoreline receptor is predicted to be contacted by floating oil concentrations at the 10 g/m^2 threshold with probability of 15%, with a corresponding minimum contact times of 5 hours (Table 3.10). At the Rowley Shoals – Clerke Reef State Marine Park and Rowley Shoals – Imperieuse Reef State Marine Park shoreline receptors, probabilities of floating oil contact at the 10 g/m^2 threshold are forecast to be 1% or less.

The Rowley Shoals – Mermaid Reef Marine Park receptor is predicted to experience shoreline oil accumulation in excess of the 100 g/m^2 threshold with a probability of 1% (Table 3.10). Potential for accumulation of oil on shorelines is predicted to be low, with a maximum accumulated volume of 6 m^3 forecast at the Rowley Shoals – Clerke Reef State Marine Park and a maximum local accumulated concentration of 491 g/m^2 forecast at the Rowley Shoals – Mermaid Reef Marine Park (Table 3.10).

The forecast annualised minimum times to contact and EMBA for floating oil at or above the 1 g/m^2 and 10 g/m^2 threshold concentrations are depicted in Figure 3.49 to Figure 3.52.

3.5.1.3 Entrained Oil

Entrained oil at concentrations equal to or greater than the 500 ppb threshold is predicted to be found up to around 371 km from the spill site (Figure 3.54).

Contact by entrained oil at concentrations equal to or greater than 500 ppb is predicted at Argo-Rowley Terrace Marine Park (57%), Rowley Shoals – Mermaid Reef Marine Park (33.5%) and Rowley Shoals – Clerke Reef State Marine Park (7.5%; Table 3.11). The maximum entrained oil concentration forecast for any receptor is predicted as 167.6 ppm at Argo-Rowley Terrace Marine Park.

The forecast annualised minimum times to contact and EMBA for entrained oil at or above the 500 ppb threshold concentration are depicted in Figure 3.55 and Figure 3.56, respectively.

The cross-sectional transects of maximum entrained oil concentrations in the vicinity of the release site show that concentrations above 25,000 ppb are expected to extend from the sea surface to depths of around 20 m (Figure 3.57).

3.5.1.4 Dissolved Aromatic Hydrocarbons

Dissolved aromatic hydrocarbons at concentrations equal to or greater than the 500 ppb threshold are predicted to be found up to around 43 km from the spill site (Figure 3.58).

Contact by dissolved aromatic hydrocarbons at concentrations equal to or greater than 500 ppb is predicted at Argo-Rowley Terrace Marine Park (8.5%) and Rowley Shoals – Mermaid Reef Marine Park (1.5%; Table 3.12). The maximum dissolved aromatic hydrocarbon concentration forecast for any receptor is predicted as 2.2 ppm at Argo-Rowley Terrace Marine Park.

The forecast annualised minimum times to contact and EMBA for dissolved aromatic hydrocarbons at or above the 500 ppb threshold concentration are depicted in Figure 3.59 and Figure 3.60, respectively.

The cross-sectional transects of maximum dissolved aromatic hydrocarbon concentrations in the vicinity of the release site show that concentrations above 2,000 ppb are expected to extend from the sea surface to depths of around 10 m (Figure 3.61).

4 DETERMINISTIC ASSESSMENT RESULTS

4.1 Overview

To provide additional context to the outcomes of the stochastic assessment presented in Section 3, deterministic model runs of interest were selected from the stochastic set of replicate simulations for each scenario according to the following criteria:

- Minimum time to floating oil contact with the offshore edge(s) of any shoreline receptor polygon (at a threshold of 10 g/m^2);
- Minimum time to entrained/dissolved oil contact with the offshore edge(s) of any shoreline receptor polygon (at a threshold of 500 ppb);
- Minimum time to commencement of oil accumulation at any shoreline receptor (at a threshold of 100 g/m^2);
- Maximum cumulative oil volume accumulated across all shoreline receptors and at any individual shoreline receptor (at concentrations in excess of 100 g/m^2).

A time series compilation of figures from each deterministic replicate simulation (i.e. a single spill event) for each scenario is presented in the following sections. Each of the figure compilations includes areal exposure at discrete time intervals during the simulation.

4.2 Scenario 1: Long-Term (77-Day) Surface/Subsea Blowout of Unstabilised Torosa Condensate at the TRA-C Well

4.2.1 Simulation with Minimum Time to Oil Contact and Accumulation at Any Shoreline Receptor at Defined Thresholds

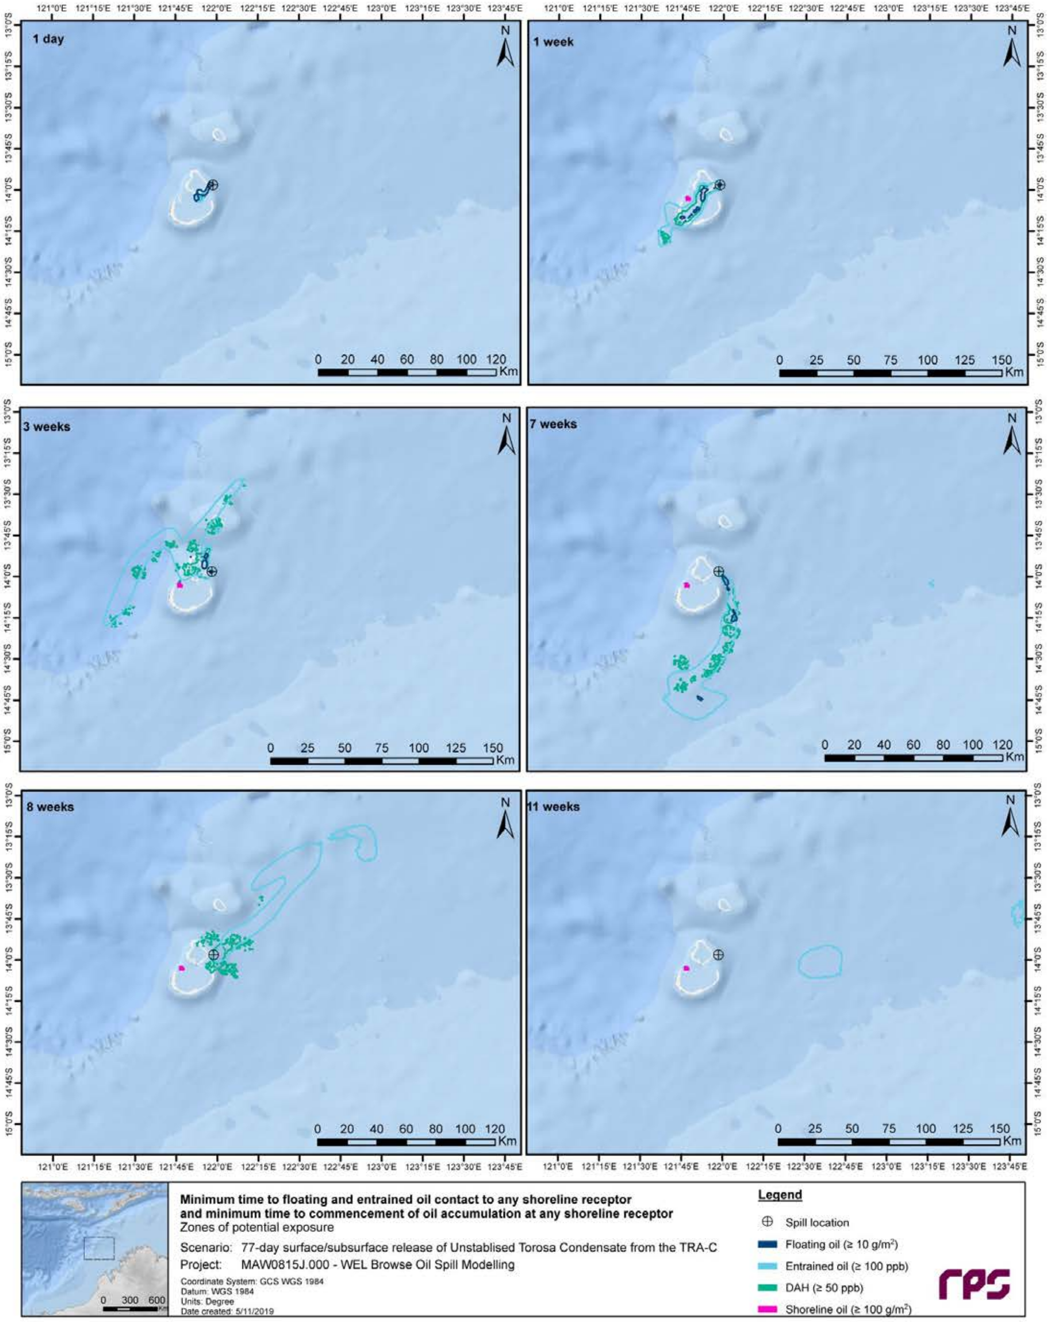

Figure 4.1 Time-varying areal extent of potential exposure at defined floating oil, entrained oil, dissolved aromatic hydrocarbon and shoreline oil threshold concentrations, resulting from a 77-day surface/subsea release of unstabilised Torosa Condensate at the TRA-C well, for the replicate case with the minimum time to floating oil contact with the offshore edge(s) of any shoreline receptor polygon (at a threshold of 10 g/m^2), the minimum time to entrained/dissolved oil contact with the offshore edge(s) of any shoreline receptor polygon (at a threshold of 500 ppb) and the minimum time to commencement of oil accumulation at any shoreline receptor (at a threshold of 100 g/m^2).

4.2.2 Simulation with Maximum Oil Accumulation across All Shoreline Receptors and at Any Individual Shoreline Receptor at Defined Threshold

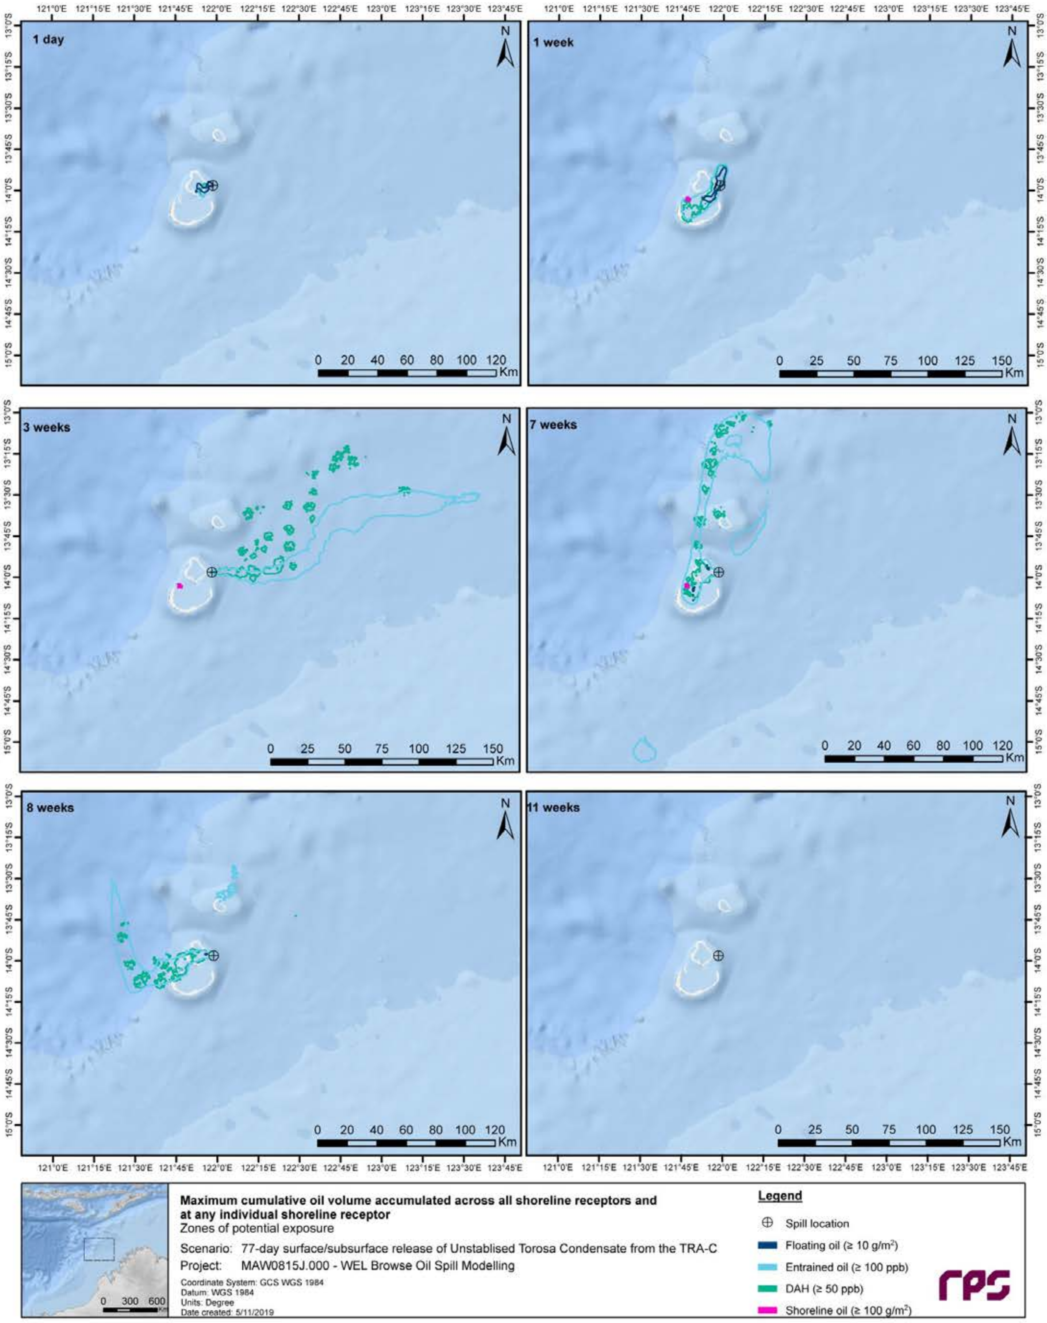

Figure 4.2 Time-varying areal extent of potential exposure at defined floating oil, entrained oil, dissolved aromatic hydrocarbon and shoreline oil threshold concentrations, resulting from a 77-day surface/subsea release of unstabilised Torosa Condensate at the TRA-C well, for the replicate case with the maximum cumulative oil volume accumulated across all shoreline receptors and at any individual shoreline receptor (exceeding a threshold of 100 g/m^2).

4.3 Scenario 2: Short-Term (24-Hour) Surface Release of Stabilised Torosa Condensate after a Vessel Cargo Tank Rupture at the Torosa FPSO Location

4.3.1 Simulation with Minimum Time to Floating Oil Contact at Any Shoreline Receptor at Defined Threshold

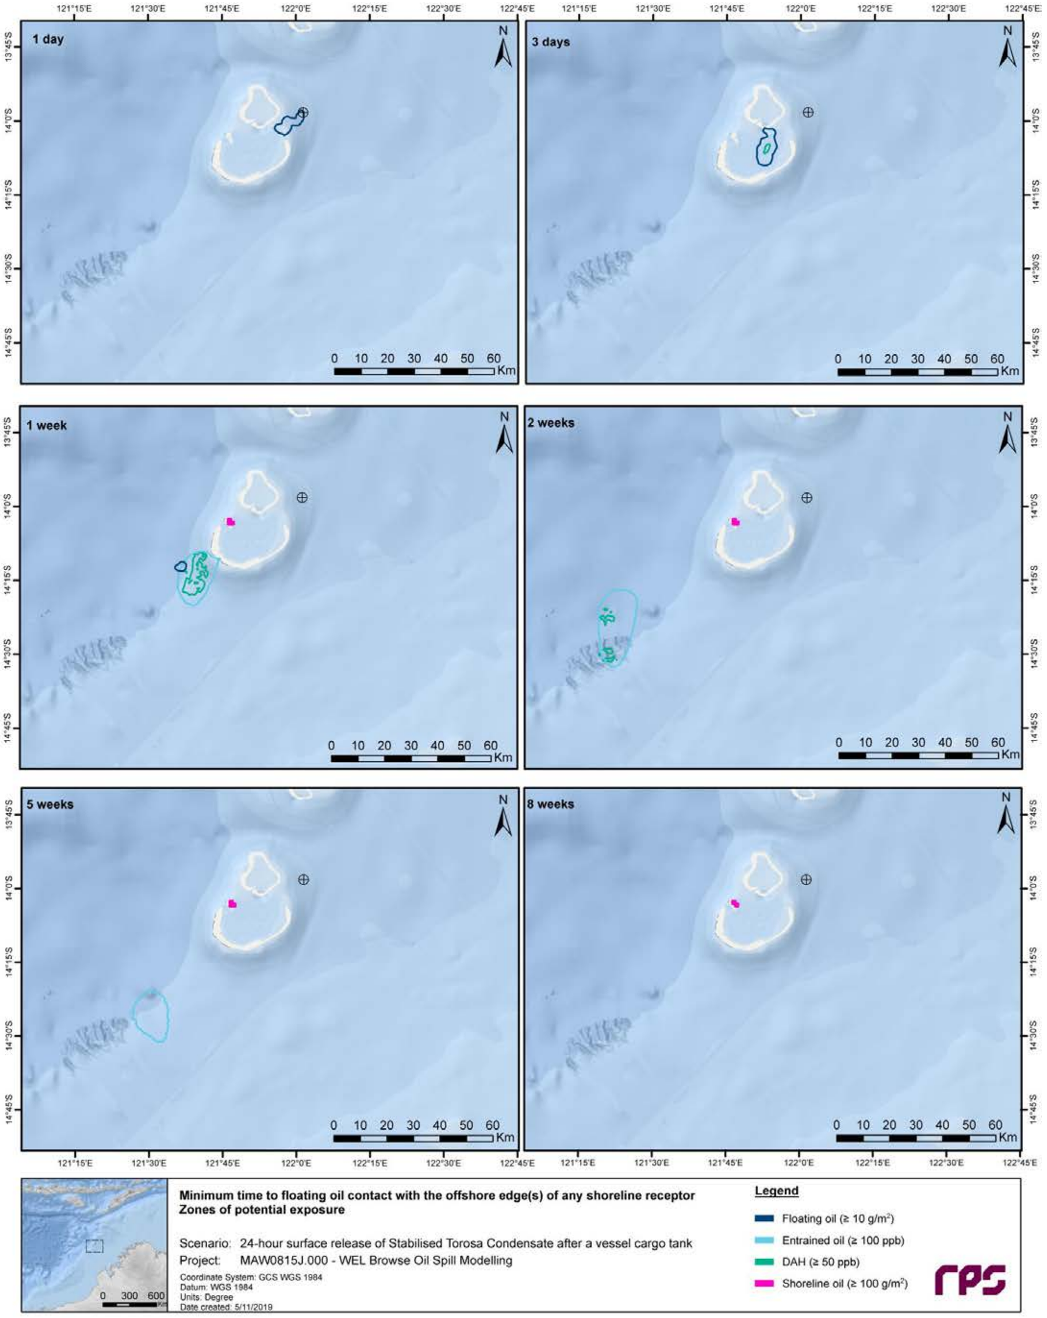

Figure 4.3 Time-varying areal extent of potential exposure at defined floating oil, entrained oil, dissolved aromatic hydrocarbon and shoreline oil threshold concentrations, resulting from a 24-hour surface release of stabilised Torosa Condensate after a vessel cargo tank rupture at the Torosa FPSO location, for the replicate case with the minimum time to floating oil contact with the offshore edge(s) of any shoreline receptor polygon (at a threshold of 10 g/m^2).

4.3.2 Simulation with Minimum Time to Entrained/Dissolved Oil Contact at Any Shoreline Receptor at Defined Threshold

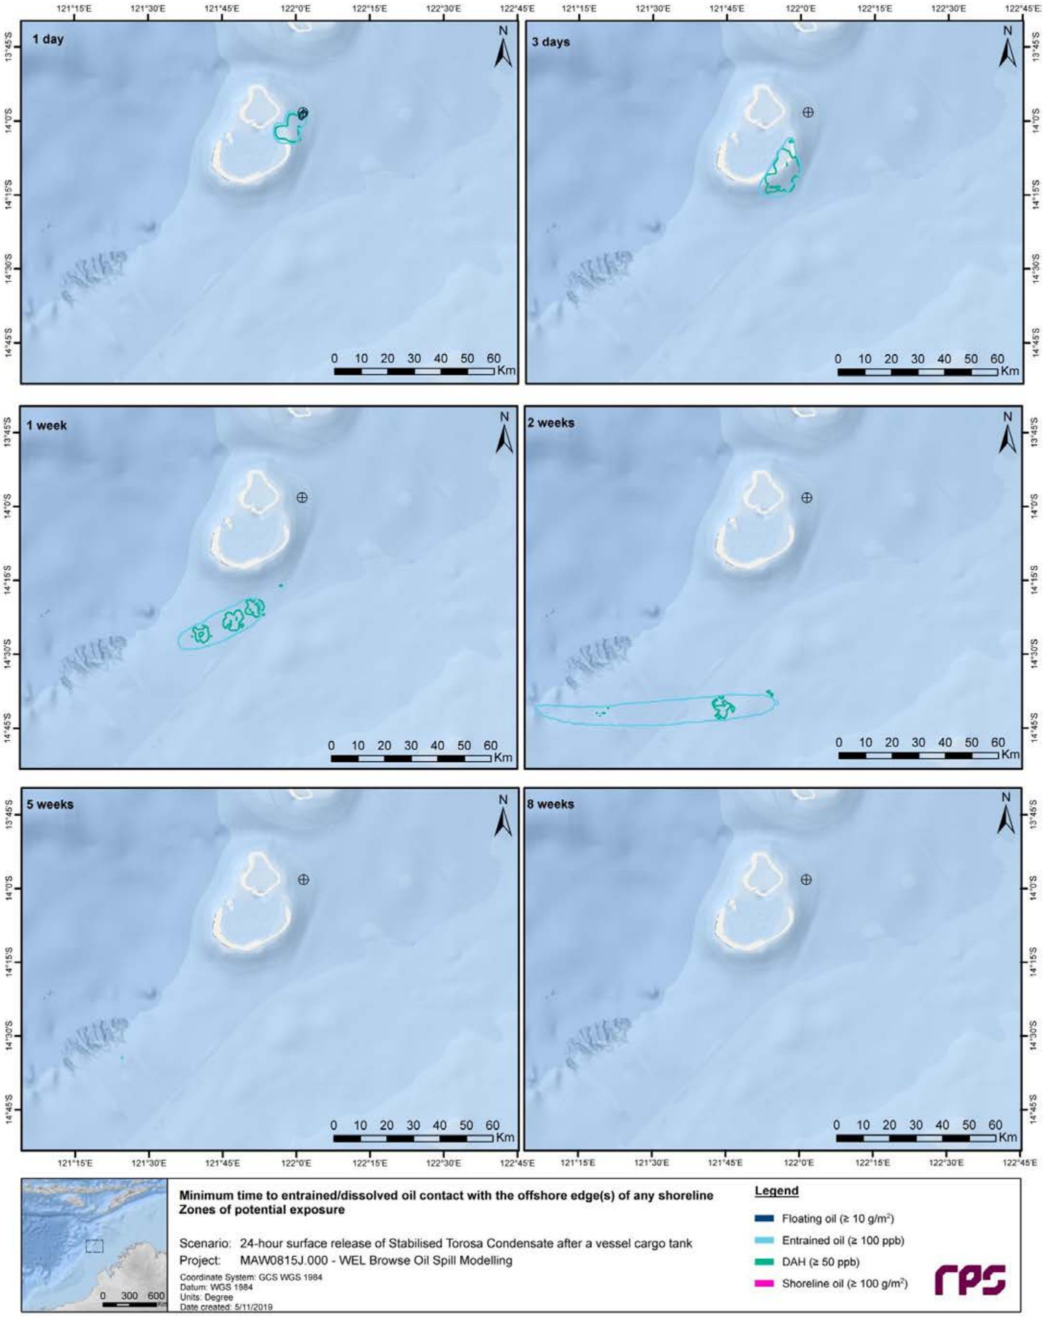

Figure 4.4 Time-varying areal extent of potential exposure at defined floating oil, entrained oil, dissolved aromatic hydrocarbon and shoreline oil threshold concentrations, resulting from a 24-hour surface release of stabilised Torosa Condensate after a vessel cargo tank rupture at the Torosa FPSO location, for the replicate case with the minimum time to entrained/dissolved oil contact with the offshore edge(s) of any shoreline receptor polygon (at a threshold of 500 ppb).

4.3.3 Simulation with Minimum Time to Oil Accumulation at Any Shoreline Receptor at Defined Threshold

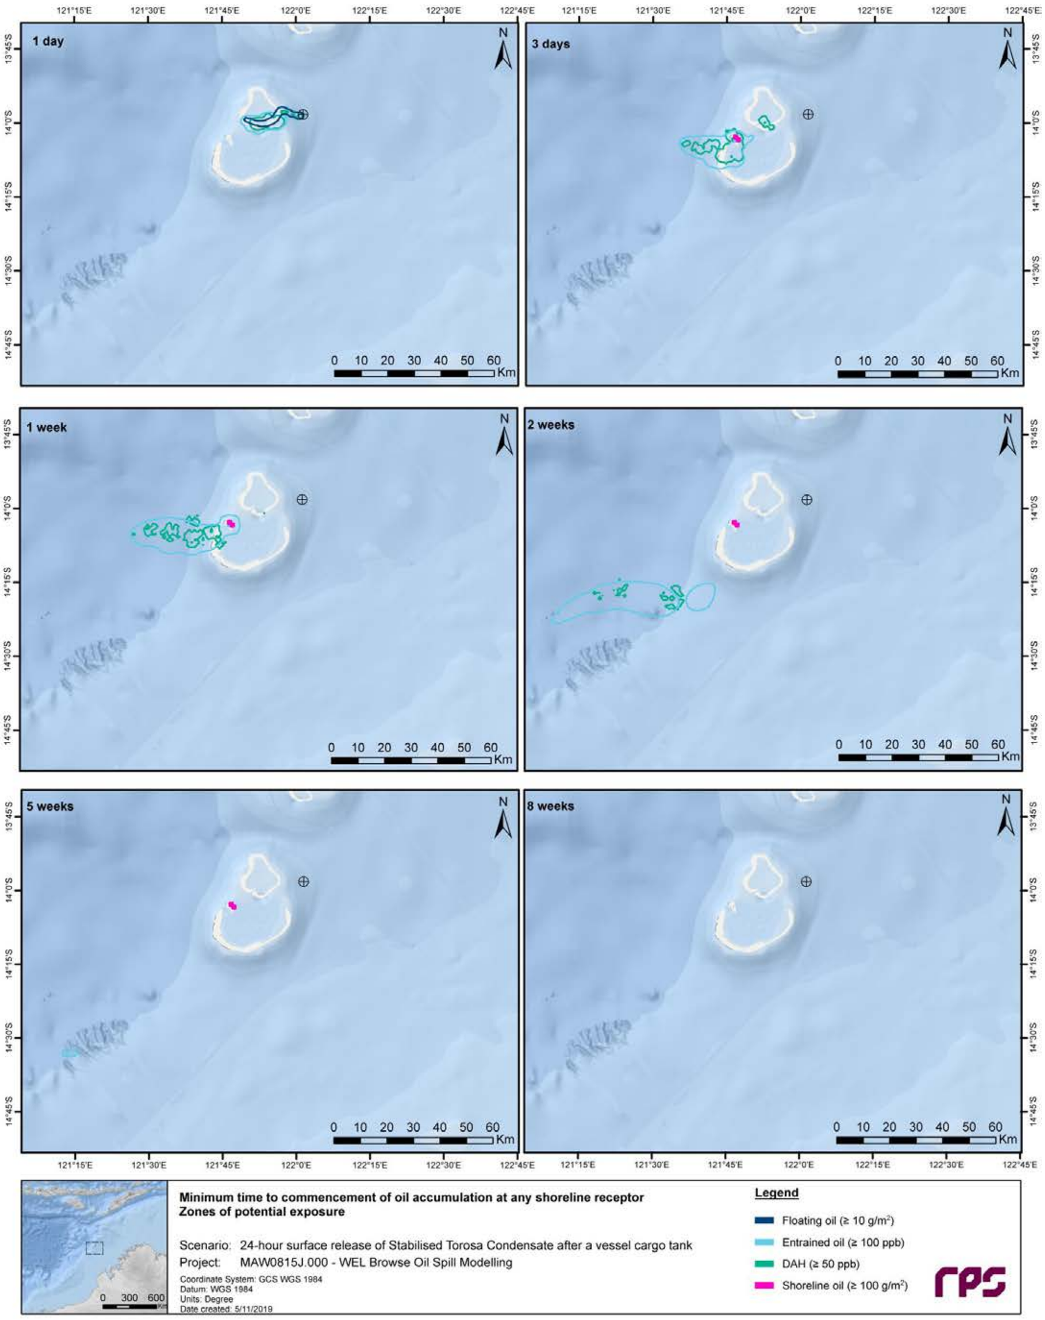

Figure 4.5 **Time-varying areal extent of potential exposure at defined floating oil, entrained oil, dissolved aromatic hydrocarbon and shoreline oil threshold concentrations, resulting from a 24-hour surface release of stabilised Torosa Condensate after a vessel cargo tank rupture at the Torosa FPSO location, for the replicate case with the minimum time to commencement of oil accumulation at any shoreline receptor (at a threshold of 100 g/m^2).**

4.3.4 Simulation with Maximum Oil Accumulation across All Shoreline Receptors and at Any Individual Shoreline Receptor at Defined Threshold

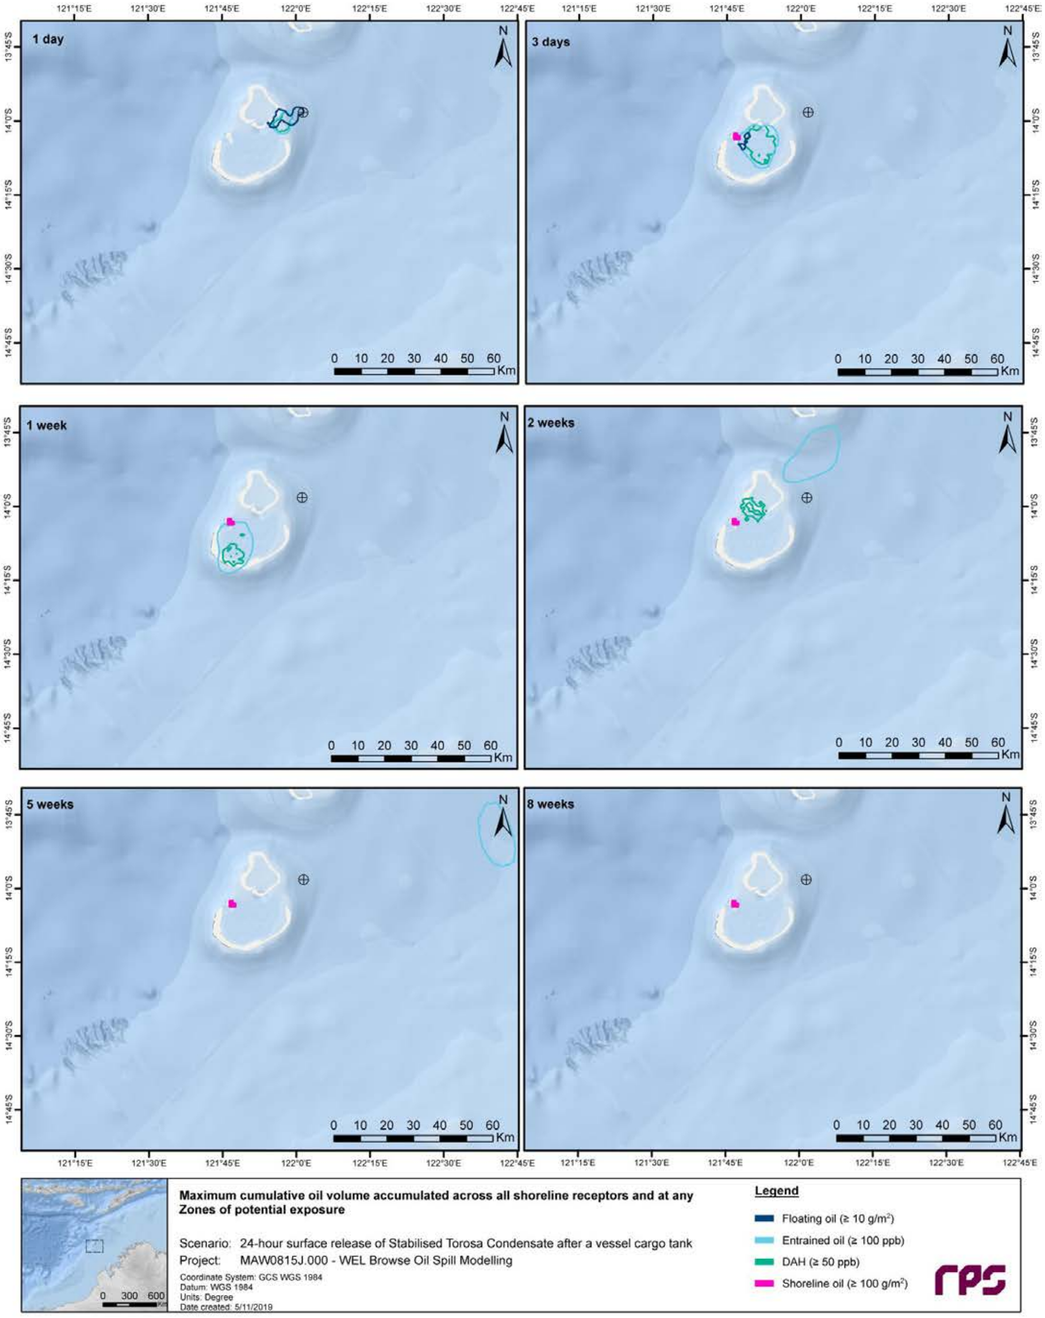

Figure 4.6 Time-varying areal extent of potential exposure at defined floating oil, entrained oil, dissolved aromatic hydrocarbon and shoreline oil threshold concentrations, resulting from a 24-hour surface release of stabilised Torosa Condensate after a vessel cargo tank rupture at the Torosa FPSO location, for the replicate case with the maximum cumulative oil volume accumulated across all shoreline receptors and at any individual shoreline receptor (exceeding a threshold of 100 g/m^2).

4.4 Scenario 3: Short-Term (Instantaneous) Surface Release of Stabilised Torosa Condensate after an FPSO Offtake System Failure at the Torosa FPSO Location

4.4.1 Simulation with Maximum Oil Accumulation across All Shoreline Receptors and at Any Individual Shoreline Receptor at Defined Threshold

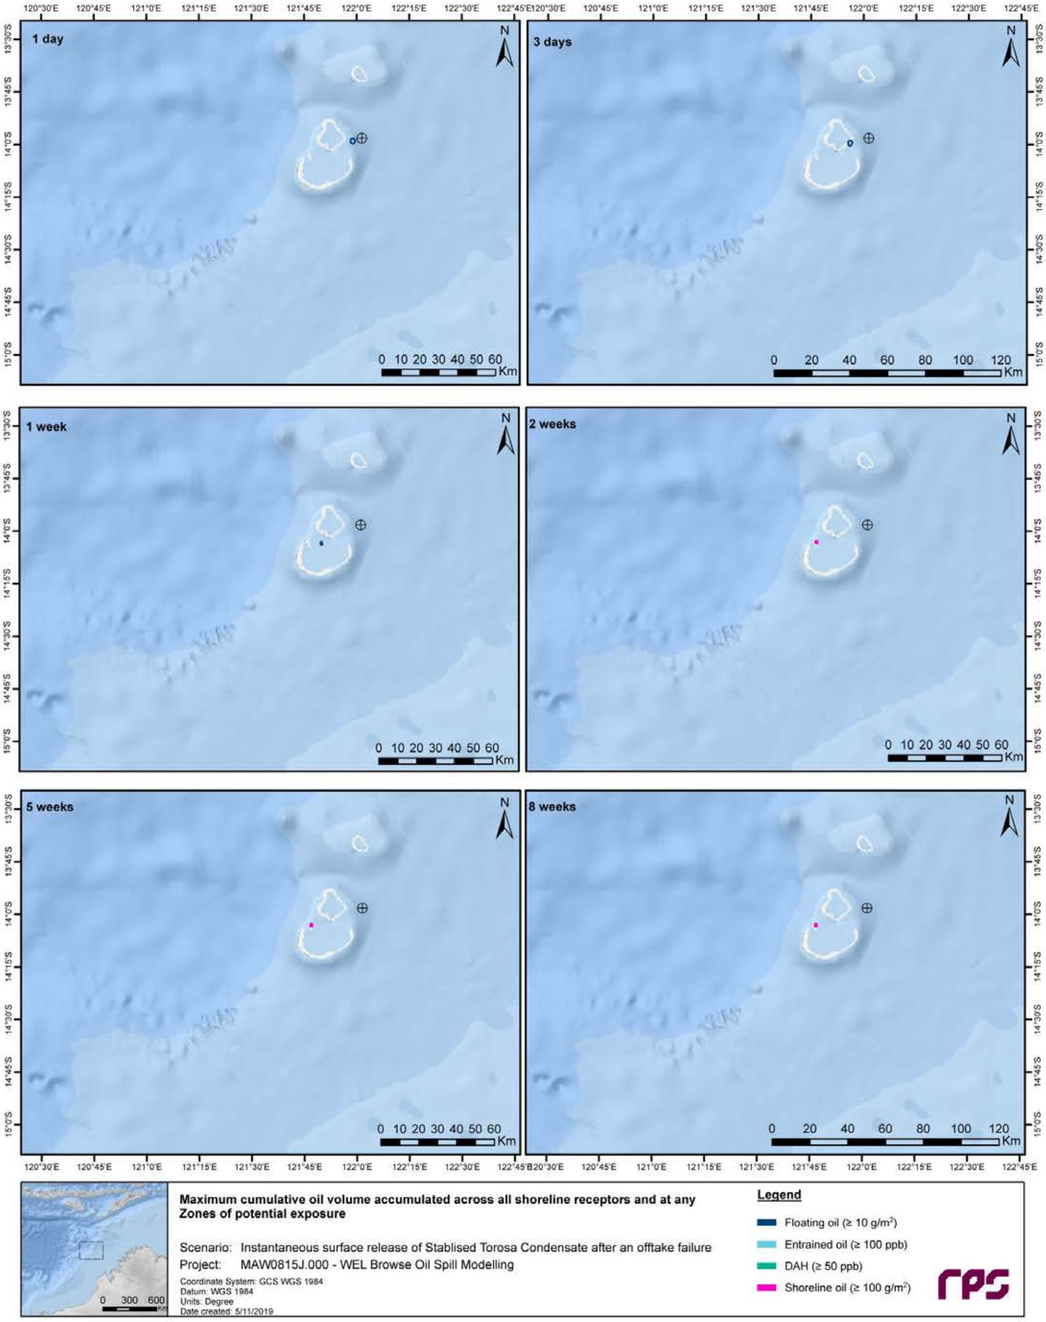

Figure 4.7 Time-varying areal extent of potential exposure at defined floating oil, entrained oil, dissolved aromatic hydrocarbon and shoreline oil threshold concentrations, resulting from an instantaneous surface release of stabilised Torosa Condensate after an FPSO offtake system failure at the Torosa FPSO location, for the replicate case with the maximum cumulative oil volume accumulated across all shoreline receptors and at any individual shoreline receptor (exceeding a threshold of 100 g/m^2).

4.5 Scenario 4: Short-Term (Instantaneous) Surface Release of Marine Diesel after a Vessel Fuel Tank Rupture near the Rowley Shoals

4.5.1 Simulation with Maximum Oil Accumulation across All Shoreline Receptors and at Any Individual Shoreline Receptor at Defined Threshold

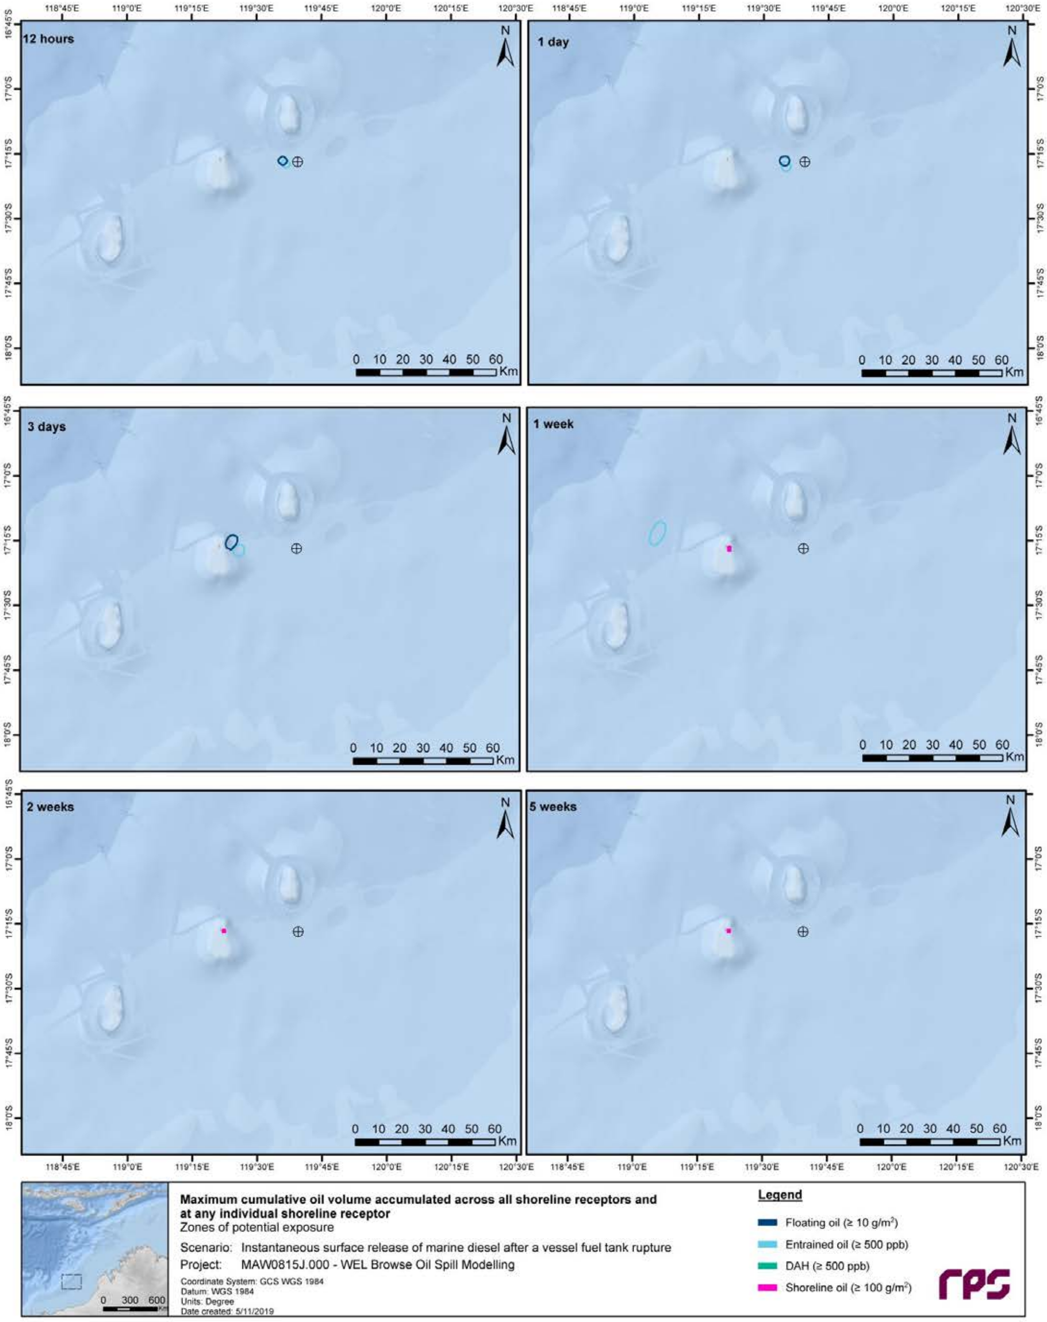

Figure 4.8 Time-varying areal extent of potential exposure at defined floating oil, entrained oil, dissolved aromatic hydrocarbon and shoreline oil threshold concentrations, resulting from an instantaneous surface release of marine diesel after a vessel fuel tank rupture near the Rowley Shoals, for the replicate case with the maximum cumulative oil volume accumulated across all shoreline receptors and at any individual shoreline receptor (exceeding a threshold of 100 g/m^2).

5 CONCLUSIONS

The main findings of this study are as follows:

Metocean Influences

- Tidal flows within the reef complex will have a significant influence on the short-term trajectory of any oil spilled at the modelled release sites, irrespective of the seasonal conditions.
- Large-scale drift currents will have a significant influence on the trajectory of any oil spilled at the modelled release sites, irrespective of the seasonal conditions. The prevailing drift currents will determine the trajectory of oil that is entrained beneath the water surface.
- Interactions with the prevailing wind will provide additional variation in the trajectory of spilled oil, and marked variation in the prevailing drift current and wind conditions will be expected over the duration of a long-term release. This will be expected to increase the spread of hydrocarbons during any single event.

Oil Characteristics

- The unstabilised Torosa Condensate mixture specified for the sea-surface release phase of the Scenario 1 blowout is a pre-processed condensate that is a mixture of volatile and persistent hydrocarbons with significant proportions of highly volatile and residual components. If the sea-surface release phase unstabilised Torosa Condensate mixture is exposed to the atmosphere, around 17% of the mass is expected to evaporate in around 24 hours, another 33% within a few days, and the remaining 51% is expected to persist in the marine environment until decayed due to photochemical and biological degradation. If the unstabilised Torosa Condensate mixture specified for the subsea release phase were to be exposed to the atmosphere, these proportions are expected to be 54%, 21% and 25%, respectively.
- Stabilised Torosa Condensate, which refers to condensate which has been processed by the FPSO and which has been considered in Scenarios 2 and 3, contains a significant proportion of volatile compounds and a low proportion of residual hydrocarbons. If exposed to the atmosphere, around 78% of the mass will be expected to evaporate in around 24 hours, another 8% within a few days, and the remaining 14% will be expected to persist in the marine environment until decayed.
- Marine diesel is a mixture of volatile and persistent hydrocarbons with low percentages of highly volatile and residual components and has been considered in Scenario 4. If exposed to the atmosphere, around 41% of the mass would be expected to evaporate in around 24 hours, another 54% within a few days, and the remaining 5% would be expected to persist in the marine environment until decayed.
- For all hydrocarbon types, the influence of entrainment will regulate the degree of mass retention in the environment.

Summary of Stochastic Assessment Results

Interpretation of Contour Figures

- The mapped spatial outcomes of the stochastic assessment for each scenario are an aggregation of the predicted oil trajectories over the full duration of many individual hydrocarbon spill simulations and indicate the probability of exposure at defined concentrations for individual locations at some point in time after commencement of the spill event.
- These outcomes do not depict a hydrocarbon slick or plume at any particular instant in time, nor do they represent the overall coverage predicted over the full duration of an individual hydrocarbon spill simulation.

Scenario 1: Long-Term (77-Day) Surface/Subsea Blowout of Unstabilised Torosa Condensate at the TRA-C Well

- The location of the release is adjacent to the Scott Reef system. Most of the predicted impacts from this scenario are focused on the receptors that comprise the Scott Reef system. Note that the set of receptor boundaries that define the Scott Reef system for the purposes of this study have some intentional overlapping areas, and this implies duplicated reporting of some oil impacts.
- Floating oil at concentrations equal to or greater than the 10 g/m^2 threshold could potentially be found up to 143 km from the spill site.
- Floating oil concentrations at the 10 g/m^2 threshold are predicted to be focused on the Scott Reef system. Floating oil at 10 g/m^2 reaches Scott Reef North in all replicate simulations, but as Scott Reef North is treated as a submerged feature floating oil is predicted to drift over rather than make direct contact with this receptor. Scott Reef Central – Sandy Islet is treated as an emergent feature. This receptor is predicted to be contacted by floating oil concentrations of 10 g/m^2 with a probability of 8% and a minimum time to contact of 46 hours after commencement of release.
- The Scott Reef Central – Sandy Islet receptor is predicted to experience shoreline oil accumulation in excess of the 100 g/m^2 threshold with a probability of 92%. With regard to shoreline receptors further from the release location, Cartier Island (22%) and Ashmore Reef (18%) are predicted to have the highest probabilities of shoreline oil accumulation in excess of the 100 g/m^2 threshold.
- Potential for accumulation of oil on shorelines is predicted to be significant for Scott Reef Central – Sandy Islet, with a maximum accumulated volume of 827 m^3 and a maximum local accumulated concentration of 34.3 kg/m^2. The predicted zone of shoreline impact is restricted to Sandy Islet. Note that the boundaries of two other receptors, Scott Reef Central and Scott Reef South, overlap with the same shoreline as Scott Reef Central – Sandy Islet so reported accumulations for these receptors are a duplication.
- Entrained oil at concentrations equal to or greater than the 100 ppb threshold is predicted to be found up to approximately 863 km from the spill site.
- Contact by entrained oil at concentrations equal to or greater than 100 ppb is generally predicted for Scott Reef receptors including Scott Reef North (100%). Seringapatam Reef is also predicted to be contacted at 100 ppb (87%).
- The maximum entrained oil concentration forecast for any receptor is predicted as 23.6 ppm at Scott Reef North.
- Dissolved aromatic hydrocarbons at concentrations equal to or greater than the 50 ppb threshold are predicted to be found up to around 673 km from the spill site.
- Contact by dissolved aromatic hydrocarbons at concentrations equal to or greater than 50 ppb is generally predicted for Scott Reef receptors including Scott Reef North (100%). Seringapatam Reef is also predicted to be contacted at 50 ppb (85%).
- The maximum dissolved aromatic hydrocarbon concentration forecast for any receptor is predicted as 13.9 ppm at Scott Reef North.

Scenario 2: Short-Term (24-Hour) Surface Release of Stabilised Torosa Condensate after a Vessel Cargo Tank Rupture at the Torosa FPSO Location

- The location of the release is adjacent to the Scott Reef system. Most of the predicted impacts from this scenario are focused on the receptors that comprise the Scott Reef system.
- Floating oil at concentrations equal to or greater than the 10 g/m^2 threshold could potentially be found up to 126 km from the spill site.

- Floating oil concentrations at the 10 g/m^2 threshold are predicted to be focused on the Scott Reef system. The Scott Reef South and Scott Reef Central shoreline receptors are predicted to be contacted by floating oil concentrations at the 10 g/m^2 threshold with probabilities of 6.5% and 2%, respectively. At these receptors, the corresponding minimum times to contact at this threshold are 21 hours and 57 hours.
- The three Scott Reef receptors that share a common shoreline, Scott Reef South, Scott Reef Central and Scott Reef Central – Sandy Islet, are predicted to experience shoreline oil accumulation in excess of the 100 g/m^2 threshold with a probability of 20.5%.
- Potential for accumulation of oil on shorelines is predicted to be moderate, with a maximum accumulated volume of 212 m^3 and a maximum local accumulated concentration of 9.5 kg/m^2 forecast at the Scott Reef South, Scott Reef Central and Scott Reef Central – Sandy Islet receptors.
- Entrained oil at concentrations equal to or greater than the 100 ppb threshold is predicted to be found up to around 890 km from the spill site.
- Contact by entrained oil at concentrations equal to or greater than 100 ppb is generally predicted for Scott Reef receptors including Scott Reef North (48.5%). Seringapatam Reef is also predicted to be contacted at 100 ppb (22.5%).
- The maximum entrained oil concentration forecast for any receptor is predicted as 30.5 ppm at Scott Reef North. This result is greater than the maximum concentration forecast in Scenario 1, where a larger total volume of oil is released. The difference in maximum entrained oil concentration is attributable to the higher release rate in Scenario 2 (18,000 m^3/day compared to 1,846 m^3/day for Scenario 1). The Scott Reef North receptor is close enough to the release site that the peak concentration is influenced more by the rate of oil released in one day than the total volume of oil released.
- Dissolved aromatic hydrocarbons at concentrations equal to or greater than the 50 ppb threshold are predicted to be found up to around 517 km from the spill site.
- Contact by dissolved aromatic hydrocarbons at concentrations equal to or greater than 50 ppb is generally predicted for Scott Reef receptors including Scott Reef North (41.5%). Seringapatam Reef is also predicted to be contacted at 50 ppb (15.5%).
- The maximum dissolved aromatic hydrocarbon concentration forecast for any receptor is predicted as 12.7 ppm at Scott Reef North.

Scenario 3: Short-Term (Instantaneous) Surface Release of Stabilised Torosa Condensate after an FPSO Offtake System Failure at the Torosa FPSO Location

- The location of the release is adjacent to the Scott Reef system. Most of the predicted impacts from this scenario are focused on the receptors that comprise the Scott Reef system.
- Floating oil at concentrations equal to or greater than the 10 g/m^2 threshold could potentially be found up to 67 km from the spill site.
- The Scott Reef South receptor is predicted to be contacted by floating oil concentrations at the 10 g/m^2 threshold with a probability of 1.5% and a minimum contact time of 24 hours.
- The Scott Reef shoreline, encompassed by the Scott Reef South, Scott Reef Central and Scott Reef Central – Sandy Islet receptors, is predicted to experience shoreline oil accumulation in excess of the 100 g/m^2 threshold with a probability of 2.5%.
- Potential for accumulation of oil on shorelines is predicted to be low, with a maximum accumulated volume of 8 m^3 and a maximum local accumulated concentration of 715 g/m^2 forecast at three Scott Reef shoreline receptors.
- Entrained oil at concentrations equal to or greater than the 100 ppb threshold is predicted to be found up to around 242 km from the spill site.

- Contact by entrained oil at concentrations equal to or greater than 100 ppb is predicted at various northern Scott Reef receptors, including Scott Reef North (28%), Scott Reef North – Flats (25%) and Scott Reef North – Lagoon (20%).
- The maximum entrained oil concentration forecast for any receptor is predicted as 6.4 ppm at Scott Reef North and Scott Reef North – Flats.
- Dissolved aromatic hydrocarbons at concentrations equal to or greater than the 50 ppb threshold are predicted to be found up to around 271 km from the spill site.
- Contact by dissolved aromatic hydrocarbons at concentrations equal to or greater than 50 ppb is predicted at Scott Reef North (23%) and Scott Reef North – Flats (22.5%).
- The maximum dissolved aromatic hydrocarbon concentration forecast for any receptor is predicted as 1.8 ppm at Scott Reef North and Scott Reef North – Lagoon.

Scenario 4: Short-Term (Instantaneous) Surface Release of Marine Diesel after a Vessel Fuel Tank Rupture near the Rowley Shoals

- The location of the release is adjacent to Mermaid Reef. Most of the predicted impacts from this scenario are focused in the vicinity of the Rowley Shoals.
- Floating oil at concentrations equal to or greater than the 10 g/m^2 threshold could potentially be found up to 82 km from the spill site.
- Given that the spill location lies within the Argo-Rowley Terrace Marine Park area, floating oil at concentrations equal to or greater than 10 g/m^2 is forecast at this receptor with a probability of 100% and a minimum time to contact of less than 1 hour. The Rowley Shoals – Mermaid Reef Marine Park shoreline receptor is predicted to be contacted by floating oil concentrations at the 10 g/m^{2}threshold with a probability of 15%, with a corresponding minimum contact time of 5 hours. At the Rowley Shoals – Clerke Reef State Marine Park and Rowley Shoals – Imperieuse Reef State Marine Park shoreline receptors, probabilities of floating oil contact at the 10 g/m^2 threshold are forecast to be 1% or less.
- The Rowley Shoals – Mermaid Reef Marine Park receptor is predicted to experience shoreline oil accumulation in excess of the 100 g/m^2 threshold with a probability of 1%.
- Potential for accumulation of oil on shorelines is predicted to be low, with a maximum accumulated volume of 6 m^3 forecast at the Rowley Shoals – Clerke Reef State Marine Park and a maximum local accumulated concentration of 491 g/m^2 forecast at the Rowley Shoals – Mermaid Reef Marine Park.
- Entrained oil at concentrations equal to or greater than the 500 ppb threshold is predicted to be found up to around 371 km from the spill site.
- Contact by entrained oil at concentrations equal to or greater than 500 ppb is predicted at Argo-Rowley Terrace Marine Park (57%), Rowley Shoals – Mermaid Reef Marine Park (33.5%) and Rowley Shoals – Clerke Reef State Marine Park (7.5%).
- The maximum entrained oil concentration forecast for any receptor is predicted as 167.6 ppm at Argo-Rowley Terrace Marine Park.
- Dissolved aromatic hydrocarbons at concentrations equal to or greater than the 500 ppb threshold are predicted to be found up to around 43 km from the spill site.
- Contact by dissolved aromatic hydrocarbons at concentrations equal to or greater than 500 ppb is predicted at Argo-Rowley Terrace Marine Park (8.5%) and Rowley Shoals – Mermaid Reef Marine Park (1.5%).
- The maximum dissolved aromatic hydrocarbon concentration forecast for any receptor is predicted as 2.2 ppm at Argo-Rowley Terrace Marine Park.
